

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at <http://books.google.com/>

THE

Medical Press and Circular. Estab. 1838.

Being the Incorporation of the Journals hitherto known as "The Medical Press"
and "The Medical Circular."

A Weekly Journal

OF

MEDICINE AND MEDICAL AFFAIRS.

FROM JANUARY TO JUNE,

1905.

LONDON: 8 HENRIETTA STREET, STRAND; DUBLIN: 16 LINCOLN PLACE.

I N D E X.

VOL. LXXIX NEW SERIES. (VOL. CXXX OLD SERIES.)

JANUARY TO JUNE, 1905.

- "A queer story," 519
 Aberdeen University (pass list), 393
 Aberystwith, health of, 343
 Abraham, Dr. P., dermatological cases, 7
 Action against a medical man, 629
 Action against an infirmary surgeon, 579
 Action against Dr. Darnell, 340
 Action of cyllin, 660
 Action of X-rays upon the spinal marrow, 538
 Acute coryza, 245, 456
 Acute interstitial keratitis, Dr. Campbell, 508
 Acute suffocative pulmonary oedema, Dr. Moorhead, 505
 Adenoma sebaceum, 406
 Admiral Rojdestvensky's illness, 543
 Adrenalin and arterio-sclerosis, 274
 Aerial convection of disease, 567
 After six years, 343
 Air embolism, 570
 Aix-la-Chapelle, 539
 Alcohol, Dr. Eccles, 30
 Alexander, Dr. W., use and progress of gynaecology, 181
 Aliens Bill, the, 434
 Alkaline saliva, 539
 Alleged poisoning on a honeymoon, 23
 Allenbury's diet, 418
 Allenbury's milk food cocoa, 258
 Allingham scholarship, 23
 Alopecia and hair dyes, 594
 Ambidexterity, Dr. Sawyer, 290
 American advertising, 410
 American medicine from a Chinese point of view, 438
 American voice, 180
 Anaesthesia by injection of stovain, 299
 Anaesthetic difficulties, Dr. Prender-ville, 346
 Anaesthetic pneumonia, Dr. W. Murrell, 1
 Anatomical bicycle pedal, 444
 Anatomy in America, 570
 Anderson's College, 391
 Anencephalic birth, repeated, Dr. D. Rorie, 55
 Ankylostomiasis in England, 68
 Annual election of the L.R.C.S.Eng., 623
 Another medical exhibition, 393
 Antagonism between bacteria, 437
 Ante-mortem clotting, Dr. P. Weber, 185
- Ante-partum insertion of perineal sutures, 68
 Anthrax, 196, 650
 Anthrax—an accident, 436
 Anthrax in West Sussex, 179
 Anthrax in Worcestershire, 49
 Anticipations of inventions, 547
 Antipyretic therapeutics, 542
 Antiseptic Analgesic, 673
 Antistreptococcus treatment of articular rheumatism, 219
 Aortic aneurysm, 431
 Aortic insufficiency, 274
 Appendicitis, 171
 Appendicitis and mineral aperient waters, Dr. D. Walsh, 186
 Appendicostomy, 627
 Appointments—end of each No.
 Arany, Dr., diabetes mellitus, 322
 Arsenic in urine, 93
 Arterio-sclerosis, 141
 Arterio-sclerosis, Dr. Curl, 560
 Arthritic pharyngitis, 379
 Articular tuberculosis, 61
 Artistic breathing, 252
 Aspects of rheumatism, the, Dr. Morison, 426
 Aspects of rheumatism in connection with skin affections, Dr. D. Walsh, 423
 Association of Medical Diplomates of Scotland, 56
 Association of Medical Diplomates of Scotland—inaugural dinner, 200
 Asthma and adrenalin, 563
 Asylum reports, 6, 30
 Atkinson, Dr., medico-legal relations of intemperance, 373
 Atrophia faciei bilateralis, 356
 Atrophy of the gastrocnemius, 458
 Attendance in confinement, 120
 Autolysis, 538
- Bacteriological department for Ren-frewshire, 468
 Bacteriological Department of the University of Durham, 687
 Bacteriological ethics, 492
 Bacteriological examinations in influenza, 300
 Bacteriology and ophthalmic surgery, 336
 Ball, Dr., conservative perineal pro-s-tatotomy (illustrated), 371
- Bangour village asylum, 579
 Bar-er, Dr., foetid bronchitis, 263
 Barlow's disease, 381
 Barr, Dr. T., organised and systematic research in ology, 239
 Basedow's disease, 61
 "Bazaar" and the appendix, 388
 Beatson, Dr., etiology of carcinoma, 236
 Beif, Mr., gift to the London Uni-versity, 339
 Belfast Corporation and public health, 19
 Belfast Ophthalmic Hospital, 341
 Belfast opinion on the "Irish Medical Directory," 324
 Belfast Maternity Hospital, 230
 Bell, Dr. B., successful treatment of foreign bodies which had been swallowed, 615
 Birmingham Hospital Sunday Fund, 343
 Birmingham, Prof., the late, 122
 Birayral, 300
 Births—end of each No.
 Birth announcements and limitation of family, 681
 Bloodless surgery, 304
 Blumenthal, Dr., chemistry of cancer, 375
 Board of National Education in Ireland and tuberculosis, 519
 Boer view of London medicine, 656
 Boils and anthrax, 379
 Bone-setting romance, 16
 Boric acid in food, 626
 Bossi's dilatation of the cervix, 60
 Brain preparation, 300
 Bramwell, Dr., word-blindness, 507
 Brandy again, 279
 Bread substitutes in diabetes, 121
 Brimacombe, Dr., fibro-cystic seba-ceous celluloma (illustrated), 549
 British Gynaecological Society, 73
 Bubonic plague in Leith, 550
 Bubonic plague in Scotland, 522, 523
 Burford, Dr., transfusion, 531; ectopic gestation, 533
 Burnet, D. J., convalescence, 209
 Burnet, Dr., therapeutics of aspirin and mesotan, 451
 Bu ton, Dr., use of pessaries under difficulties, 669
- Cairo School of Medicine, 179, 259
 Callous gastric ulcers, 380
 Cameron Memorial Hospital, 553
- Campaign against tubercle in the United States, 16
 Campbell, Dr., acute interstitial kera-titis, 508
 Cancer, 108
 Cancer aquaticus deformans, 405
 Cancer of the uterus, Prof. Jacobs (illustrated), 501
 Capillary bronchitis in children, 484
 Carbon monoxide poisoning, Dr. W. J. Thompson, 426
 Carcinoma, Dr. Mon-errat, 610
 Carcinoma, inoperable, 674
 Carcinoma of the eyelid, 273
 Care of consumptives in Dublin, 386
 Care of the feeble-minded, 443
 Carnegie trust, 283
 Carcinoderma pigmentosa, 332
 Cardiac neuroses, 647
 Cases of fibroma and of carcinoma of the ovary, Dr. Macnaughton-Jones, 187
 Caterpillar rash, 281
 Cats and dogs, 281
 Cavernoma of cranium, 356
 Celery and cheese, 682
 Centenary banquet of the Royal Medical and Chirurgical Society, 552
 Centenary of the Royal College of Surgeons, Edinburgh, fourth, 499
 Central Midwives Board, 123, 150, 327, 536
 Central Midwives Board and the Belfast Maternity Hospital, 628
 Cerebral cyst, 138
 Cerebro-spinal meningitis, 437, 438, 499, 564, 569
 Certification of deaths, 253
 Chair of midwifery, Edinburgh, 605
 Challenge to Mr. Coroner Troutbeck, 389
 Channels of elimination of bacteria, 438
 Chemists and bacteriology, 337
 Chemists' Exhibition, 315
 Chemistry of cancer, Dr. Blumenthal, 375
 Child suicide, 411
 China cup of cheeriness and comfort, 339
 Chinese manners, 520
 Chloride of barium in pleurisy, 484
 Chloroform; death under, 661
 Chloroform drop bottle (illustrated), 496
 Chloroform in acute uræmia, 432

Choice of treatment for fibro-myoma of the uterus, Dr. Parsons, 291
Cholelithiasis, 397
Christian science, 570
Chronic appendicitis, 9
Chronic epithelioma following hydrati-form mole—hysterectomy, Mr. H. Tweedy, 107
Chronic acetanilid poisoning, 679
Chronic pulmonary inflammation, 565
Citarin, 405
Clinical examination of salivas, 198
Clinical observations on new remedies, Dr. N. Tirard, 29
Clinical report of the Rotunda Hospital, Dr. E. H. Tweedy, 635
Coat-tar Vinolia soap, 633
Cocaine poisoning, 33
Cocaine, Dr., the occurrence of sudden death, 158
Colitis mucosa, 674
Colles's fracture, Mr. A. Fullerton (illustrated), 555, 570, 586
Coller, Mr. M., the tympanum an abscess cavity, 317
Comparative valuation of disinfectants, Mr. Moor, 29
Complement of blood in pulmonary tuberculosis, 646
Composition of nostrums, 652
Compressed air in the treatment of disease, 415
Compulsory treatment, 519
Compulsory vaccination in America, 396
Concomitancy of trachoma, 67
Confederation of the London Medical Societies, proposed, 365
Conference on hospital administration, 334
Congenital thorax paralyticus, 646
Congress of school hygiene, 99
Conjoint examinations in Ireland (pass list), 125, 259, 369, 443, 527
Conjoint examinations in Scotland (pass list), 179, 369, 443
Consent to operation, 623
Conservative perineal prostatectomy (illustrated), Dr. Ball, 371
Constitutional tendencies to disease, Dr. MacLachlan, 349
Consultations by telephone, 438
Consumption and travel, 680
Consumption in Ireland, 251
Consumptive homes, 19
Continental health resorts, 597
Contractility of the unimpregnated uterus, Dr. A. Duke, 80
Contravention of public health act, 20
Control of proprietary medicines, 336
Convalescence, Dr. J. Burnet, 209
Co-operation of London medical schools, 548
Copper as a disinfectant, 199
Copyright in cancer cinematograms, 49

THE OPERATING THEATRES.

CANCER HOSPITAL—
 Removal of the appendix and ovary, 515
 BECKENHAM COTTAGE HOSPITAL—
 New method of dealing with hæmorrhage from the stomach, when no bleeding point can be found, 140
 BURFORD COTTAGE HOSPITAL—
 Squamous epithelioma of the mucous membrane of the lip, 85
 CHELSEA HOSPITAL FOR WOMEN—
 Hysterectomy, 406
 FRENCH HOSPITAL AND DISPENSARY—
 Jacksonian epilepsy, 597, 647
 GREAT NORTHERN HOSPITAL—
 Cerebral abscess, 167
 Inguinal laparotomy in an infant, 11
 Suppurative appendicitis, 514
 GUY'S HOSPITAL—
 Chronic constipation and its results, 433
 Early tuberculous nephritis with strong fibrous adhesions, 301
 Fracture of the tibia and fibula, 433
 Hydronephrosis due to movable kidney, 301
 Irreducible suo-coraoid dislocation of the humerus, 433
 Sequela of a pylorotomy, 114
 Simple fracture of the femur in a woman, æt. 72, 620
 Simple spiral fracture at the hip joint, 620
 HOSPITAL FOR SICK CHILDREN—
 Dilatation of the stomach in a girl, æt. 6, 620
 ITALIAN HOSPITAL—
 Appendicitis, 333
 Removal of an abdominal cyst, 221
 Removal of the uterus and the ovary, 62
 Squamous epithelioma of the lower lip, 486
 KING'S COLLEGE HOSPITAL—
 Epididymectomy, 358
 Pstterior gastro enterostomy, 192
 Ileo-colostomy for malignant tumour of the cæcum, 648
 MIDDLESEX HOSPITAL—
 Perforated duodenal ulcer and dilated stomach, 486
 NORTH-WEST LONDON HOSPITAL—
 Complete removal of half the tongue, 540
 Enlarged spleen in front or right kidney simulating renal tumour, 140
 Large ovarian cystoma, 114
 Removal of a large vesical calculus, 275
 Tuberculosis of vermiform appendix, 406
 ROYAL EAR HOSPITAL—
 Influenzal mastoiditis, 358
 Radical mastoid operation, 34
 Submucous resection of the nasal septum, 675
 Suppurative disease of the labyrinth, 85
 ROYAL FREE HOSPITAL—
 Separation of the lower femoral epiphysis, 458
 ROYAL WESTMINSTER OPHTHALMIC HOSPITAL—
 Piece of steel inside the eye removed by means of Haab's electromagnet, 246
 ST. BARTHOLOMEW'S HOSPITAL—
 Loose body in knee-joint, 332
 ST. PETER'S HOSPITAL—
 Papilloma of the bladder, 167
 ST. THOMAS'S HOSPITAL—
 Nephrectomy for carcinoma of the kidney, 11
 Ruptured ovarian cyst with an inguinal hernia, 221
 Tuberculous disease of the appendix and cæcum, 565
 TOTTENHAM HOSPITAL—
 Abdominal hysterectomy for fibrosis, 62
 Diseased appendages, 676
 Intestinal obstruction in a woman of advanced age, 35

Unusual cause for rectal hæmorrhage in a boy, 276
 WEST LONDON HOSPITAL—
 Cholecystectomy, 38

ANÆSTHETIC PNEUMONIA.

By WILLIAM MURRELL, M.D., F.R.C.P.,

Physician to the Westminster Hospital, Examiner in the University of Aberdeen.

OBJECTION may be taken to the use of this term on the grounds that the lung condition is not always the result of the administration of an anæsthetic, and that when it does occur it is not, as a rule, a true pneumonia. In the majority of cases it is a catarrhal bronchorrhœa followed by œdema of the lungs. It is met with most frequently after the administration of ether, but is occasionally seen after chloroform, even when not given by gas or candle-light. I know of no case after nitrous oxide or ethyl chloride. Ether pneumonia may be due to the irritation produced by the anæsthetic itself, to exposure of the patient to cold, especially in prolonged abdominal explorations, and possibly in some cases to the use of a contaminated mouth-piece. It is said to be more common after "anæsthetic ether," sp. gr. 0.717, than after "ether purus," sp. gr. 0.720. At the Westminster Hospital the latter is always employed, and there have been no accidents. Ether excites a hypersecretion of saliva, and as the mouth contains many pathogenic organisms it is conceivable that in deep respiration pneumococci may be drawn into the lungs and set up aspiration pneumonia. It is more common in hospital work than in private practice, possibly because in most hospitals the patient is taken out of a hot operating theatre through draughty passages into a ward, the windows of which are always open. The risk might possibly be obviated by pulling a veil over the patient's head during the process of removal, and by taking him temporarily to a small ward well warmed and free from draughts. In private practice the operation is usually performed in a room at a temperature of 70°, and the patient is well covered with blankets and kept warm with hot-water bottles. The administration of ether lowers the bodily temperature, which, in a prolonged operation, may fall from two to four degrees. The employment of special hot-water operating tables is worth considering, especially when the patient is prone to bronchitis. A well-known anæsthetist attributes the freedom from lung complications in his cases to the fact that he never allows the windows to be opened after an operation. Attention to this point is of some importance, as the friends nearly always want the windows opened in order to get rid of the, to them, objectionable smell of ether. It has been sug-

gested that prior to the administration of the anæsthetic, the mouth, throat and nasal passages should be rendered aseptic by the use of a mouth-wash and gargle, but what is of far more importance is to sterilise the mouth-piece. In the case of a woman, æt. 59, who died with the symptoms of pneumonia on the third day after the administration of five ounces of anæsthetic ether for an operation lasting fifty minutes, the reporter attributed the fatal result, not to the anæsthetic, but to "shock and infection." He stated that he found afterwards that a visitor who was present had come straight from the *post-mortem* room to the operation. Such undesirable visitors should be excluded.

It is difficult to obtain accurate statistics of these cases, partly from the fact that there are many complicating factors which are difficult to eliminate, and to a greater extent to the circumstance that in few hospitals is an "anæsthetic register" kept. A register of anæsthetics, stating the nature of the operation, its duration, the nature and quantity of the anæsthetic employed, and any after-effect observed, would afford useful data for comparison. Many anæsthetists of wide experience have never met with cases of this description, but from statements derived from various sources I am inclined to think that bronchial complications of one kind or another are seen in, roughly, one in fifteen hundred cases of ether administration. A case which attracted some attention not long ago was that of a well-known artist who was operated on under chloroform and a very little ether in a nursing home in London. He apparently recovered perfectly from the effects of the operation and the anæsthetic, but twenty-six hours later there was hypersecretion of bronchial fluid which caused death from asphyxia in less than half an hour. I know, too, by hearsay, of a case in which a similar disastrous effect followed the administration of ether by the rectum for an operation on the larynx. Some years ago I saw in consultation a young engineer suffering from chronic bronchitis and emphysema. His story, and it was confirmed by his doctor, was that two years previously, his teeth being in a very bad condition, he decided to have them removed that a denture might be fitted. On a cold winter's day he went to a dentist's, and was shown into a room without a fire. He was told to remove his coat and collar, and a cold mackintosh was wrapped about his neck. He was placed in a chair opposite a window, from which a cold draught descended like a douche. He had gas and ether, and the operation lasted over an hour. When he

recovered consciousness he was thoroughly chilled and for some time was laid up with acute bronchitis, from which he dated all his subsequent sufferings.

With regard to anæsthetic pneumonia, it should be treated on ordinary principles. The symptoms may make their appearance in from five to seven hours after the operation, or they may be postponed for some days. The cases of hypersecretion present no difficulty, for many years ago it was shown by Ringer and myself, working independently, that atropine was the physiological antidote to this condition, and that it was prompt in its action. The patient should be inverted so as to allow the fluid to run out of the mouth, and he should be given a hypodermic injection of 1-60th grain or more of sulphate of atropine.

Therapeutic Notes.

GLYCOTHYMOLINE AS AN ORO-NASAL AND A GENERAL ANTISEPTIC.

By DAVID WALSH, M.D. Edin.,

Senior Physician, Western Skin Hospital, London, W., &c.

It is only by slow degrees that medical men as a profession are learning to realise the important part played by bacteria in the cavities of the nose and mouth. One sign of this appreciation may be found in the fact that washes and gargles for the mouth and throat are being more and more adopted in everyday practice. The systematic use of such applications, however, so far as the nostrils are concerned, is for the most part still confined to specialists. One reason for this comparative neglect of a simple method of treatment by general practitioners has no doubt hitherto lain in the difficulty of obtaining a safe and, at the same time, an efficient antiseptic and cleansing fluid for the mucous membranes in question.

Glycothymoline was brought to my notice as an excellent lotion for nasal and oral sprays and washes. On due inquiry it was found to fulfil the two conditions usually recognised by medical men in the United Kingdom as vouching for the character, so to speak, of such a preparation. First, its advertisements are accepted by our three leading medical journals, namely, the *British Medical Journal*, the *Lancet*, and THE MEDICAL PRESS AND CIRCULAR. Secondly, its composition is not a secret, its formula being freely published. Under these circumstances, I determined to try the effect of this preparation in a few suitable cases. As a general antiseptic fluid that does not coagulate albumen, and is non-irritant, deodorant and practically non-poisonous, glycothymoline has clearly a wide range of usefulness. My own observations, however, have been practically confined to its use in the nose and mouth, with results that have proved satisfactory in every instance, especially in acute coryza, pharyngitis, influenza, and septic conditions of the mouth.

Case 1.—A. B., male, æt. 37, came to hospital complaining of partial loss of hair of moustache. The patient had been under treatment at various skin hospitals for a chronic eczematous condition of the upper lip and loss of hairs of upper border of moustache. On inquiry, he was found to be subject to frequent "colds in the head." This condition is not uncommon in skin clinics. Suitable ointments and lotions were

ordered for the eczematous condition, and patient was directed to douche the nostrils with a glycothymoline solution, 1 in 3 of water, twice daily. After a few weeks of this treatment the lip showed great improvement, and now is on the high road to recovery, with signs of re-growth of hair.

Case 2.—C. D., acute coryza in a young married woman, somewhat anæmic, otherwise healthy; on the second day of attack, with profuse watery discharge and frontal headache. Coryza cut short and immediate relief of symptoms. Other cases of this kind might be quoted in which acute nasal catarrh was promptly abated and sometimes cured.

Case 3.—E. F., male, æt. 50, chronic nasal catarrh, with deflected septum and frequent blocking of left nostril. During a bout of foggy weather in London the discomfort of the chronic condition was aggravated by acute catarrh, with "sore throat," partial deafness, frontal headache and watery discharge. The use of a spray of glycothymoline, 1 in 3, several times daily, gave great relief, and under this treatment the left nostril was always free. The amount of black matter washed out of the nostrils by the spray bore eloquent testimony to the sootiness of London fogs. (It is unnecessary to quote other cases of chronic nasal catarrh and obstruction benefited in the same way.)

Case 4.—G. H., female, æt. 32, influenza, second day of attack, much prostration, frontal headaches, temperature 102°, profuse nasal discharge, slight sore throat, tongue slightly furred, constipation, complete loss of appetite, pains in the back. This patient was kept in bed and a spray of glycothymoline, 1 in 3, applied frequently to the nose. At the same time a dose of quinine and a purgative, with nutritious food and stimulants, were ordered. The catarrhal symptoms quickly subsided, and the patient recovered more rapidly than in any one of several previous attacks. This result she herself attributed to the nasal spray.

Case 5.—K. L., female, æt. 45. Patient complained of great pain in upper gum, where a swelling had been incised some days previously. The tongue was furred, pus was exuding from the "gumboil," and the breath was offensive. The frequent use of glycothymoline as a wash (warm) afforded immediate relief. The patient was enthusiastic in her praise of the remedy.

Case 6.—M. N., male, æt. 45. Primary epithelioma of soft palate, advanced stage (six months' duration). The tonsils, pharynx and base of tongue had become involved, and the foetid condition of breath and of discharges was most marked when the use of glycothymoline was begun as a spray to the nostrils and to the mouth and pharynx. Under this treatment the parts became clean and sweet, and, to the relief both of patient and attendants, remained so until the end, some six months later. The checking of secondary septic processes in the oro-nasal cavity no doubt lessened the general discomforts of the patient.

Cases 7 and 8.—These were both external wounds seen at hospital. The one was a burn of scalp, and the other a chronic non-specific ulcer of the leg in a middle-aged hard-working woman of poor health, who had borne a large family. In both cases the glycothymoline proved an excellent healing lotion. The ulcer especially, which had been under every conceivable kind of medical

treatment for years, received more benefit from the application (according to the patient's testimony) than from any other single remedy. Owing to conditions of environment and of deficient vitality, the ulcer failed to heal completely.

On this evidence it seems clear that in glycothymoline we have a good and safe application in all septic conditions of the mouth, throat and nose. It seems not improbable that in the near future medical men will attend more than they have done hitherto to the mucous membranes of the upper respiratory tract in influenza, measles, scarlatina, chronic and acute coryza, whooping-cough, and other infectious ailments. Post-nasal catarrh—that curse of modern civilisation—has never been adequately attacked by the general practitioner. Carious teeth, again, another defect of civilisation, are apt to damage the general health considerably. In both these conditions glycothymoline will be found a safe and effective remedy well worth a careful trial in practice.

Vienna Clinical Lectures.

THE CLINICAL VALUE OF RADIOGRAPHY IN TRAUMATIC INTRA-MUSCULAR OSTEOMAS.

By DR. R. KIENBÖCK,

Principal of the Radiographic Institution, Vienna.

PART I.

THE following remarks will be directed to an anatomical and clinical description of our present knowledge of traumatic intra-muscular osteomas; particularly their origin, type, localisation, histology, and hypotheses advanced. Twenty cases will be taken from medical literature on the subject, with eight cases investigated by the writer, and his clinical note. The principal part of the subject will be the radiographic anatomy with the changes observed during the first week or month after the injury to the part, and the importance of a negative diagnosis when no shadow of an osteoma is to be observed about the bone. The angle of diagnosis will also be referred to as an important factor in recognition of these neoplasms where the whole circumference of the diaphysis becomes porous and elevated in the neighbourhood of the osteoma, presumably from a separation or detachment of the periosteum. Differential diagnosis is another practical point deserving notice, as it is not always easy to say whether any of these neoplasms are simple intra-tendinous ossifications, progressive myositis ossificans, multiple cartilaginous exostoses, or some other hard accumulations of debris. A fitting conclusion will be the experience of Honzer, Schuler, and Courtin with Holzknicht's theory of fibrous ossification and functional accommodation.

The first step necessary for a clear understanding of intra-muscular osteomas and their pathology will be a brief glance at the anatomy of the part, with the clinical history of the common changes.

Intra-muscular traumatic osteoma may be defined as a bone-like scar in the muscle after an injury of varying intensity, and, properly speaking, may be classified as myositis ossificans. The injuries necessary for its production are often very slight as well as severe. The adductors of the upper part of the leg from riding long is not an uncommon source of origin; the shoulder from long carrying a heavy gun, or the deltoid from strained exercise, as well as severe injury, are all to be traced as the first or starting points of the pathological change, which would not unreasonably point to some other more remote factor in the production of the subsequent phenomena. Be

that as it may, we will not enter on that abstruse phase at present, but confine our attention to those causes that appeal most forcibly to our senses, *vis.*, severe injuries to the part, as first described by Otto in 1816, and thereafter followed by Scherb, 1854, and Rokitsansky in 1856.

It is a curious fact that this disease tends to locate itself about the upper part of the leg and shoulder after severe accidents, such as a kick from a horse, distortion or dislocation of an arm by falls, twists, &c., that frequently are met with in balancers, acrobats, &c., who are putting great strain on these particular muscles by tension or falls in the performance of their various avocations.

Whatever the real cause of the disease, little or no pain attends its course after the accident itself. If the patient be carefully observed, nothing clinically will be found after he has perfectly recovered and resumed his duty. As a general rule, there is no solution of continuity at the seat of injury as far as can be seen by the attendant, although there may be the swelling and discoloration present that usually follow all contusions; even movement in the part may be performed without any evidence of pain or stiffness in the limb. In spite of this apparent happy result of the accident, such as a dislocation of the shoulder, knee, or elbow, a week after a gradual feeling of uneasiness may set in, subsequently followed in the course of a few more weeks by a hardness near the joint. The swelling is usually to be felt lying in the direction of the bone, not regular, but uneven, with round pieces here and there that can be lifted quite up from the bone with the muscle. These neoplasms are not confined to the diaphysis of either the femur or the humerus, but are seen to extend along the muscles on contraction and retraction, as if they were placed in series along the sheaths of the muscles as hard elongated nodules. The period that elapses after the accident before the appearance of these hard concretions is arranged as Münchmeyer has done for operation purposes into three stages, *vis.* :—

(1) Inter- and intra-muscular changes in the fibrous tissue, with swelling in the muscles, accompanied with reactive œdema.

(2) The stage of fibrous tissue induration and shrinking of the neoplastic growth.

(3) The final stage of ossification and union of the isolated parts.

In the greatest number of cases operation is delayed till the third stage has been reached, or till ossification has been clearly demonstrated. In all cases of operation the muscles will be found to have been crushed, the vessels torn, or hæmorrhagic effusion into the affected part has occurred. The local conditions usually indicate a lesion of some kind in the region affected, particularly the soft tissues over the hard diaphysis. In the case of the arm this explanation is conclusive, where a luxation of the forearm at the elbow would throw it back on the humerus, injuring the periosteum, tearing the tendons and muscles by the displacement of the three bones involved in the joint. In the case of the arm the principal muscles injured would be the brachialis internus and biceps, by the enormous distension over the epiphysis of the humerus, while the quadriceps cruris would be similarly affected in the lower extremity. The ossification of the latter has often run its course so rapidly that cases have had to be operated on within a week of the lesion where true bone has been present. In some cases this hardness varies from hard bands of cartilage to genuine bone itself; indeed, all three forms may be present, as bone in thin plates covered with cartilage and hard tissue, which may form the separating line between the true tissue and neoplasm, where cysts and fluids often form to add to the enlargement.

We now come to the more speculative part of the subject—the origin of bone formation. Is the product inflammatory?

Wide differences of opinion have raged round this point of inflammatory or simple growth. In some

of the cases coming under my own observation the latter has prevailed, commencing in the intra-muscular fibrous tissue and gradually affecting the torn fibres in the muscle.

Another advocates the metaplastic theory that the muscular fibre itself is converted into fibrous tissue first, then cartilage, and finally bone. The greatest number of authors now concur in Virchow's opinion that the osteoma is intra-muscular and inflammatory in origin, although he was inclined to believe in an ossifying diathesis, as many cases occur where greater destruction of muscle takes place with no subsequent ossification. Possibly the peculiarity of the injury to the muscle itself may be the immediate cause.

There is yet another point that has been widely discussed, whether the fibrous tissue that forms along the muscle is a projection of the periosteum from the bone, or is it a genuine outcome of the fasciculi of the muscle, or from the fibre of the muscle itself? Whatever may be the true history of the case, it is found that the greatest number of cases have their origin in connection with the periosteum of the diaphysis of the bone, and the lesion is never far removed from this source, which conveys the general conviction that all presumptive, isolated osteomas are only prolongations of periosteum in some form, as fine pedicles have been traced in many secondary osteomas of this character. The rapid formation of a hard, resistant substance shortly after does not militate against this theory, as Borchard relates a case of a groom who received a kick from a horse on the side of the face, whereby the masseter muscle became ossified within twenty-one days after the accident, and whose origin was traced to the periosteum. Many eminent investigators, however, have traced no connection, and firmly believe in a primary intra-muscular osteoma. It may even be osteophytic in origin, and by some proximate change in the fibrous tissue become transformed into an ossified growth. In this connection it might be well to quote Holzkecht's experience, which he gave to the profession a year ago:—"In some of these cases local irritation of the periosteum will be met with, where a sort of ossified callus will be found. But there are other cases where the fibrous tissue becomes ossified without any apparent connection with the periosteum, spreading deep into the muscular tissue or inserting itself between the fibrous bundles of the muscular fasciculi. These insertions form exostoses, whose processes may again be traced to the periosteum, and thus circuitously back to the periosteum. We may therefore conclude that there is some common pathology in all these extra-ossæous formations, although the cause and effect are not easy of demonstration." The results of radiography are in favour of an "intra-muscular, traumatic osteoma," but, unhappily for this hypothesis, no traumatic conditions can be discovered in many of the cases investigated.

A short *résumé* of some of the cases met with in literature may assist us in forming a judgment on the subject.

Bremig reports a lady, *æt.* 19, having received a kick from a horse on the hip, which seven weeks later became hard and resisting. After examination with the Röntgen rays, it was resolved to remove the osteoma. The femur was in no way changed.

Courtin showed a radiogram recently of a boy, *æt.* 11, who had luxation of the left elbow-joint, followed six weeks after with an osteoma of the brachialis. This appeared to be connected with the epiphysis in origin, though actually in the muscle.

Rothschild records one in the right brachialis muscle of a young man, *æt.* 38, a few months after hard driving. The radiogram shows the bony structure rising from the lower part of the humerus in the fasciculi of the internal brachialis, and winding round the tendons as well as the muscle.

Köhler shows another of the elbow in a patient, *æt.* 47, where the brachialis internus muscle is involved and again traced to the diaphysis. This osteoma

appeared about five years after the supposed injury. There seems to have been some pain in movement in this case, with a well-defined tumour.

The same author records a case in the lower third of the femur, occurring in a boy, *æt.* 16. On the anterior side of the femur, about 8 centimetres above the patella, a hard tumour was present. No particular time could be assigned to the accident, but it is supposed to have occurred in childhood. The osteoma resembled a cabbage, and was connected with the diaphysis by a long pedicle.

Rammstedt gives the history of an officer, *æt.* 23, who received a kick from his horse on the hip, and two months later a hard, resistant tumour formed in the injured region. With the rays was observed a shadow 15 centimetres long and about 6 or 7 centimetres from the lower end of the femur, apparently situated in *mus. vastus internus*. The movements of the knee were so limited that an operation was necessary.

The same author gives the Röntgenograms of a groom, *æt.* 18, who had a kick on the middle third of the femur of the left leg, which showed no connection with the diaphysis, although the periosteum was found on operation to be much swollen and elevated with osteophytes. The microscope proved the tumour to be composed of fibrous tissue, cartilage, and bone.

Grünbaum showed radiograms to the *Gesellschaft der Aerzte* of a labourer, *æt.* 54, who sustained a severe blow from a falling plank on the femur. It was followed by pain, swelling, and discoloration of the skin, which a month later became hard and immobile, with stiffness of the knee. The radiogram showed a long, dark mass along a great length of the femur.

Berndt gives radiograms of two cases, *æt.* 10 and 21 respectively, who suffered from kicks. In both cases the shadows obtained are in front of healthy femurs. Both were operated on, and when closely examined were found to have originated in the periosteum. The microscope confirmed the opinion that the neoplasm was derived from fibrous, cartilaginous, and osseous tissue. This led Berndt to conclude that the periosteum was the proximate source of all these osseous formations in muscles, while Bremig and Rothschild as confidently affirm that the diaphysis is the genetic source of the neoplasm, as they always find a clear zone in the radiogram between the tumour and diaphysis, which would not be if it were connected with the periosteum. Berndt further asserts that he traced the pedicle to the spongiose portion of the bone.

The same author records a third case, where the traumatic centre was in the quadriceps, but strange to say no shadow could be observed by the Röntgen rays. The operation proved the neoplasm to be a bony structure of the spongiose class.

Overman has collected 55 records of this disease, of which 11 are not proved to be genuine traumatic cases. Two of the cases seem to be exostoses. He relates one of his own, a Hussar who received a kick from his horse. Nine months after a hard tumour, palpable and visible by the Röntgen rays, resembling bone, appeared. There were also dark shadows lying along the femur, betraying some relationship. By the operation three hard bodies were extracted from the *vastus externus*, bound up with fibrous and membranous tissue.

Schulze found, in a case of a kick from a horse on the upper part of the femur, a hard, resistant tumour which left the contour of the femur unchanged in the radiogram, but the operation revealed an osseous cyst in communication with the periosteum, where the femur seemed to have been in contact.

Schuler tells how pressure on the femur produced a hard swelling in two cases, which remained unchanged for 1½ and 2½ years respectively. The Röntgen rays showed a distinct stalactite connection with the femur.

Another case, of a man, *æt.* 22, who, after a fall on ice,

had a hard swelling, 2½ months after which the radiogram showed two hard growths lying parallel with the femur, with two fine connections to the periosteum. Later the hard tumour was removed, but unexpectedly recurred.

He also relates the case of a student, æt. 20, who had received an injury to the deltoid, after which a hard tumour appeared over the insertion of the *atissimus dorsi* and *teres major* into the humerus.

Schuler remarked that he had seen many different forms, some connected with the periosteum, others were not.

Depages gives the radiogram of a colleague, æt. 30, who, after a fall on the arm, had a swelling about the size of a walnut over the elbow two months after, which interfered with the movement of the elbow, and for which it was extirpated.

A second case was five months after the trauma on the deltoid. The rays showed its connection with the glenoid cavity.

Zimmermann records under "Myositis Ossificans Traumatica," a young man, æt. 24, who had received an injury in the *brachialis internus*, after which an osseous swelling occurred, and was removed. The rays previously showed its connection with the humerus.

Hannecast relates the history of several traumatic osteomas, among which is a wound cutting the soft tissue of the thumb, fourteen days after which an elongated osteoma appeared in the muscles of the thumb.

In another of the elbow from contusion, the same results occurred, with immobility of the elbow-joint.

Farganel tells how a soldier in turning a *soubresant* had a sprain at the thigh in the right leg. After two weeks a slight swelling commenced, spindle-shaped and bony hard. The rays added nothing to the diagnosis. As the leg became very limited in movement it had to be operated on, which revealed an osteoma 14 centimetres long and 1·8 broad. Recovery was complete.

Having reviewed the experience of other observers, I shall now venture to place eight of my own cases before you.

Case I.—A female, æt. 33, came to me in 1898 to be examined by the rays. Six weeks prior to this she had a dislocation of the left elbow-joint which was immediately after reduced. Gradually after this time a tumour was observed to form above the joint, which interfered with its movement, as there

FIG. 1.

CASE I.—Left Elbow, Medical Section. Half the natural size.

was slight pain on pressure. The radiogram, as shown in the accompanying diagram (Fig. 1), revealed a hard, bony structure at the lower front part of the humerus, which was separated by a clear zone

FIG. 2.

CASE III.—Right Elbow. Medical Section. Half natural size; 12 years old, with open epiphyseal union.

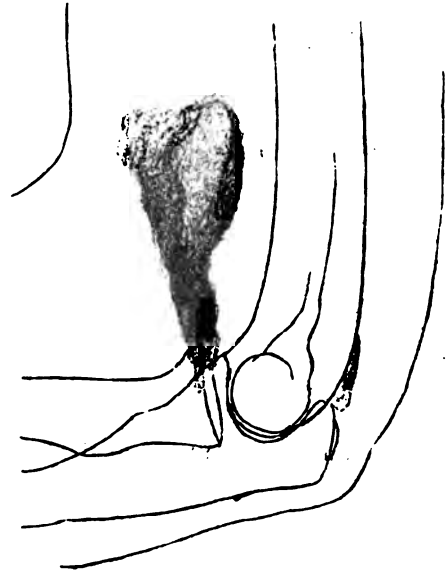

FIG. 3.

CASE IV.—Right Elbow. Medical Picture. Half natural size.

from another swelling or shadow higher up the bone and deeper in the limb. Both shadows were very dark, with apparent bands of connection. Posteriorly a dark band was observed to pass downwards closer to the humerus behind, extending in to the joint with a clear zone like the others, uniting it with the diaphysis of the long bone. No trace of any lesion could be observed in humerus, radius or ulna. In this case mechanical treatment was persevered in, and no operation performed, as the patient objected. Strange to say, this treatment had the effect of checking any further growth. It is now five years since the accident, and at the present time very little swelling can be seen with fairly good movement, which gives him a feeling of tearing the sinews of his arm when in motion. The osteoma may be said to be at a standstill in this case.

Case II is a man, æt. 31, who three and a half months before examination had fallen on his right

elbow, which was immediately followed by pain and swelling of the joint, with a good deal of discoloration, and inability to bend the limb. The swelling at the time of examination was smooth, hard, immovable, and about the size of a large nut, that prevented the complete flexing of the arm. The Röntgen rays gave a shadow 2 centimetres long and 1 broad immediately in front of the distal end of the humerus, with a delicate white band, 6 mm. wide, running into the union of the epiphysis at right angles to the humerus. The skeleton was quite normal, except this attachment. The treatment adopted was massage and passive movement.

Case III is a strong, healthy-looking boy, æt. 12, who eight weeks before skiagraphing had an awkward fall on his right arm while at his gymnastic exercise, which caused the elbow to swell and become discoloured, with great tenderness on pressure. With suffusions the swelling soon disappeared, but the power of extension and flexion was greatly impaired by a round hard tumour immediately above the elbow-joint, movable from side to side, and smooth on the surface. The radiogram is given in Fig. 2, lying as an oval swelling in front of the elbow-joint, while the radius, ulna, and humerus are quite normal, with no apparent direct connection between the tumour and epiphysis. It measured 4·8 centimetres long and 2·1 broad. The neoplasm was not homogeneous, but appeared to be composed of irregular bands, thus making the surface uneven.

In this case an operation was performed, and the osteoma extirpated from the brachialis muscle. No bands could be traced to the humerus or coronoideus ulnæ. The histological composition of the neoplasm was cartilage, fibrous tissue, and layers of bony structure.

(To be concluded in our next issue.)

Lunacy Department.

ASYLUM REPORTS.

Argyle and Bute District Asylum, Lochgilphead.—The number of patients admitted to this asylum during the year was 73, as compared with 67 in the preceding year; 34 were men and 39 women. The average age of the patients admitted was 48 years; 34 suffered from some form of bodily disease, and 18 of the remainder were in impaired general health. It is very interesting to note in the report of this asylum that no case of general paralysis of the insane has been admitted during the last three years, and the last general paralytic in the house died a few months ago. The recovery-rate was 31·5; nineteen of the cases which recovered had been under treatment for less than one year, and one patient recovered after upwards of twenty years' residence. Dr. Cameron states that eleven patients were received in such an enfeebled state of health that they died within periods varying from a few hours to thirty-three days after admission; the average duration of residence of these cases was only thirteen days. This practice of sending patients in a moribund condition to asylums is becoming much too common, and some drastic measure ought to be taken to remedy this. Doubtless in such cases the medical man who is called into certify a patient insane, and also certifies the patient to be in a sufficiently good state of bodily health to be removed to an asylum, is much to blame. In many such cases we see at once on admission that they are suffering from nothing short of the delirium of death; this reflects gravely on the medical man who signs such certificates. The Commissioners in their report speak well of the management and care taken of the patients in this asylum.

Govan District Asylum, Hawkhead.—The total number of patients under care and treatment during the year in this asylum was 750. The average daily number resident was 480; the recovery-rate was 43·8 on admissions, and the deaths numbered 66. Dr. Watson, in his report, discusses very fully the causes assigned in the various cases of insanity and the defects of this method of investigation. He states that the chief fallacies are of two kinds: those affecting the observer, and those affecting the field of observation. After pointing out how absolutely worthless the information obtained from the patient's relatives often is, he states that the investigator himself must be a psychologist in more than name; without a keen and penetrating eye for character he will be unable to estimate the value of evidence, to discriminate between what is actually true and what his informant merely believes; but all his psychology and patience will be thrown away unless he chances to possess the rare gift of the scientific spirit. Men of this stamp, he says, are hard to find, and, without disrespect to an estimable body of men, one may doubt if many medical officers of asylums even approach the standard. The whole of Dr. Watson's report affords much profitable and interesting reading. The Commissioners, in their report, strongly recommend the introduction of electric lighting because of the dinginess of the walls caused by the unprotected gas-burners. Enlargement of the pathological department is being carried out; three rooms for pathological, chemical and bacteriological research respectively are being added. In the case of injuries inflicted by a male attendant on a patient the matter was reported to the Procurator-Fiscal. The attendant was tried and found guilty, and fined £5 or twenty-one days' imprisonment. Such incidents, we are glad to say, occur seldom in this our day, and are most unpleasant to all concerned in the treatment of the insane. Yet, good may result by showing to the public, who still tend to be suspicious of the treatment that goes on within asylum walls, how seriously such offences are now viewed by those in authority. The general condition in which the patients were found is reported on most favourably by the Commissioners.

Kirkland's Asylum, Bothwell.—Dr. Skeen, in his report, states that the total number of patients under treatment during the year was 286, with an average number in residence of 215. The recoveries show a percentage of 33. The cases admitted, primarily due to the action of alcohol, number 8—not a large proportion; while its action, combined with other causes, can be traced in 4 other cases—a total of 12 or 15 per cent. of the total admissions. This, in the light of other statements on the subject, may appear very small, but we agree with Dr. Skeen in thinking that much exaggeration has of late been indulged in with reference to this matter. The married men's houses, the single men's home, and the nurses' home are now in occupation. In the single men's home there is accommodation for eight single men and a house for the head male attendant, who supervises them. It is well and comfortably furnished, while the isolation from the asylum, with the quietness and privacy they obtain, is fully appreciated by its occupants. The behaviour of the men lodged there is in every way as good as when lodged in the asylum. This, we learn, is the first home of such a kind built in

connection with any asylum in Scotland, and it is gratifying to learn that it works so successfully. The Commissioners, in their report, recommend the acquiring of more land for this asylum, as the asylum buildings are outgrowing the small amount of land in connection with the Institution, and there is no site for such necessary additions as future requirements are certain to demand. This report contains much that is interesting and readable.

The Out-Patient Departments.

WEST LONDON HOSPITAL.

Dermatological Cases under the care of
DR. P. S. ABRAHAM.

[Reported by DR. G. N. MEACHEN.]

CASE I.—**SCLERODERMIA WITH BULLÆ AND ULCERATION.**—A widow, æt. 58, came on July 30th, 1904, with a sore place on her left leg. According to her account, the limb had been somewhat white and shiny for the last twelve months, but three months ago she first noticed some little, dry, raised patches which turned to small blisters upon the front of the shin. The other leg was affected to a lesser extent, but both ached very much when kept for long in a vertical position. Soon afterwards two large blisters appeared which "ran together," subsequently breaking and leaving a sore place of which she then complained. She had had three children, the youngest being twenty years old, and no miscarriages.

On examination, there were three large bullæ situated upon the front of the left leg, about the size of a small hen's egg, and filled with a brownish-looking fluid. Above and external to the largest bullæ was an irregularly shaped ulcer, with an indolent-looking base. The margins of the ulcer and the integument over the front of the upper part of the tibia as far as the tubercle was shiny, and presented the characteristic "hidebound" appearance and feel of sclerodermia. There were some minute varicosities just below the knee. The condition in the opposite leg was sclerodermatous, but there was no ulceration.

Dr. Abraham remarked that the presence of bullæ and ulceration upon a sclerodermatous area was exceedingly rare, and only a few cases had ever been seen. The more usual complication was that of atrophy, in which the affected areas presented a sunken appearance. Some pigmentation was generally observed in connection with sclerodermia, though it was not a specially marked feature of this case. A mild antiseptic lotion and ointment were prescribed, and rest in the horizontal position was enjoined as far as possible. When the bullæ had shrivelled and the ulcer showed signs of healing, the affected area was exposed to the X-rays, which proved most beneficial. (The case was afterwards shown before the West London Medico-Chirurgical Society.)

CASE II.—**BILATERAL HERPES ZOSTER.**—The patient was a boy, æt. 14, who was first seen on December 2nd, 1904. Five days previously an eruption of small blisters had appeared upon his face, preceded by some neuralgia. His general health had been affected to a slight extent, and the tongue was furred.

On examination, typical patches of herpes were seen covering the submaxillary, submental, labial, and malar regions upon both sides. The auricles were red, and a few herpetic vesicles were seen along the margins of the right pinna and tragus. The inter-orbital region also showed a small patch. The temperature was 100.2. There was a slight enlargement of the lymphatic glands beneath the chin.

It was remarked that exceptions to the unilateral distribution of herpes zoster were distinctly rare, and such had been observed by Elliott, Finny, Colcott, Fox, and others. The level of the eruption upon both sides was not always the same, this being specially the case in zoster of the chest or abdomen. The peculiarity of this case was its abundant distribution upon

corresponding parts of the two sides of the face. The parts about the ears showed quite an inflammatory reaction. No lesions were seen upon the buccal mucous membrane, though these were commonly observed in cases of severe facial herpes.

The boy was given a simple ointment with which to smear the areas and protect them from friction, and a quinine mixture to be taken three times a day.

Transactions of Societies.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.
CLINICAL MEETING HELD DECEMBER 21ST, 1904.

DR. J. O. AFFLECK, Vice-President, in the Chair.

PROFESSOR SCHAFER demonstrated his method of artificial respiration, of which extreme simplicity was an important feature. The patient is placed in the prone position, and the operator kneels by his side facing in the direction of the patient's head, and in such a position that his hands rest on the lower part of each side of the thorax. By allowing the weight of his body to fall on his arms the operator thus compresses the thorax and squeezes air out; by raising the body the thorax is allowed to expand and air enters. It was quite easy for one man to keep up artificial respiration for an hour in this way, which was not the case in Sylvester's method. The advantages of the prone position were that the tongue did not fall back, and that water, mucus, &c., escaped readily from the mouth, that more air was driven from and entered the thorax at each stroke than in Howard's method, and that there was not the same liability to fracture of ribs and injury to the liver as in Howard's method.

Dr. W. ALLAN JAMIESON exhibited a case of Extensive Tertiary Serpiginous Eruption, showing the advantage of combining local and constitutional treatment. After disappearing on the administration of iodide the eruption had recurred within two months of the cessation of the drug. It had then been scraped, in addition to being treated with iodide, and the cure had been much more permanent. (2) A case of Lichen Planus which was fading, and showed a peculiar brownish coloration.

Dr. NORMAN WALKER showed (1) two cases of Keloid situated in the typical position over the manubrium sterni. Under treatment by the X-rays considerable amelioration had taken place, the pain in particular having been much diminished. (2) Two cured cases of Lupus, one of which had had no treatment for eighteen months. In both cases the X-rays had been used, and the results had been, so far, permanently good.

Dr. DAWSON TURNER showed (1) a case of Tic Doloureux of one month's duration, for which various remedies, including extraction of all the teeth, had been fruitlessly tried, cured by the use of the static breeze. (2) A case of Epithelioma of the Lip of two years' duration, treated by radium and X-rays. (3) Two cases of Non-healing Ulcer healed by X-rays; and (4) Injury to the foot healed by sinusoidal currents.

Mr. HODSON showed a child, æt. 3, after primary disarticulation at the hip-joint for injury. Attention was drawn to the immense value of intravenous injection of saline and adrenalin in warding off shock in such cases.

Mr. C. W. CATHCART showed (1) a patient who had suffered for nine months from Pott's Disease and Pressure Paraplegia. He also had a tuberculous testicle. Laminectomy at the level of the tenth and eleventh dorsal spines showed that the cord was compressed anteriorly. After the operation the patient rapidly improved, and could (in nine months' time) walk quite well in a go-cart. (2) A patient who some months ago had come complaining of a painful swelling in the back of the neck, which ultimately resolved itself into an abscess, and was opened. The patient

was then lost sight of, and when seen again was found to have paralysis of his arms and legs, the paralysis having begun very soon after the incision of the abscess. Removal of a lamina and scraping away of a mass of granulation tissue in the spinal canal was followed by complete recovery. (3) A patient after incision of the kidney for Septic Nephritis and Pyelitis. The temperature had fallen, and there was great general improvement.

Dr. MACKENZIE JOHNSTON showed a patient after Extradural Abscess following mastoid disease. There was also sinus thrombosis, and the noteworthy point was that the girl, though the condition had been going on for a week or longer, walked up to hospital without much sign of discomfort or appearance of illness.

Mr. F. M. CAIRD showed (1) a patient after operation for Contracture of the Muscles of the Forearm. After an injury of doubtful nature to the elbow-joint, which had been healed by bandaging in a rectangular splint, wrist-drop had developed. When Mr. Caird first saw the case it closely resembled the appearance of musculo-spinal paralysis, and in fact there was a scar of a previous operation for stretching the musculo-spinal nerve. The wrist-drop, however, was due to contracture, not to paralysis, and the case was an example of what was called "ischemic paralysis" or "contracture": it was caused by pressure of bandages and occurred mostly in young subjects. The treatment was to split and suture the tendons. (2) A second case of the same condition, treated by splitting and suture of the lengthened flexor tendons, in which a secondary contracture of the extensor muscles had occurred. (3) A patient after extirpation of the rectum and anus for a cancer of four years' duration by the combined abdominal and perineal route. (4) A patient after suture of two successive perforating gastric ulcers. There was a rather prolonged history of gastric disturbance. At the second operation the stomach was found to have an hour-glass constriction resulting from the suture of the first ulcer, so a gastro-entostomy was performed at the same time.

Mr. ALEXIS THOMSON showed a case of gout, from which very large tophaceous concretions had, from time to time, been removed.

Mr. COTTERILL showed specimens of (1) ileo-cæcal intussusception; (2) hydronephrosis; (3) loose bodies from the knee-joint; and (4) cancer of stomach; and Mr. CAIRD (1) rectum removed from patient referred to above; (2) tuberculous kidney, with drawings illustrating the results gained by Luy's separator; and (3) preparation of stomach, showing posterior gastro-jejuno-stomy and lateral anastomosis.

THE OTOLOGICAL SOCIETY OF THE UNITED KINGDOM.

ANNUAL MEETING HELD DECEMBER 5TH, 1904.

The President, DR. THOMAS BARR, in the Chair.

AFTER the election of Officers and Members of Council for the ensuing Session, 1904-05, a list of whom will be found in our "Medical News" column, the meeting resolved itself into the usual ordinary meeting, under the same presidency.

INFLUENZAL LEPTO-MENINGITIS.

Mr. A. E. CUMBERBATCH read notes of a case of fatal lepto-meningitis following upon acute suppurative otitis media of influenzal origin. The antrum, sulcus lateralis, and the upper surface of the tegmen tympani were explored by the usual radical operation. A small quantity of pus was found in the antrum, but none in the other places mentioned. No symptoms of any kind, except a rise of temperature to 106° F., followed the operation. At the *post-mortem* examination, purulent lepto-meningitis was found; but no direct communication between the meningeal lesion and the middle ear could be discovered. Mr. Cumberbatch suggested that it would be well in all acute cases, where exploration of the mastoid failed to give relief, to explore the sulcus lateralis and the middle fossa of the skull. He also asked whether anything further could be done, and for

the experience of members in the use of antistreptococcal serum injections of 10 c.c. every hour.

The PRESIDENT and Dr. URBAN PRITCHARD considered the prognosis of lepto-meningitis in influenza to be absolutely bad.

Mr. ARTHUR CHEATLE thought there ought to be no question of further exploration when the mastoid operation failed to give relief.

Dr. MILLIGAN thought draining the subarachnoid space afforded a chance of relief.

Mr. C. A. BALLANCE distinguished between two forms of lepto-meningitis—one, where the pus lay between the dura and pia mater, and was fairly limited, in which operation gave a good chance of success, and another, where the pus lay between the pia and brain, and followed the prolongation of the pia into the fissures and sulci of the brain, in which it was quite impossible to drain away the pus. Mr. Ballance further reminded members that meningitis might occur in influenza independently of any middle ear suppuration.

Dr. DUNDAS GRANT referred to the recent paper of Lermoyez, in which he advocated repeated lumbar puncture in the treatment of otitic meningitis.

Mr. HUGH E. JONES related two cases operated on by him in which he found the second form of lepto-meningitis described by Mr. Ballance, and in which extensive removal of bone and multiple punctures of the pia arachnoid failed to drain away the semi-solid pus present.

GENERALISED TINNITUS.

Dr. FURNISS POTTER reported a case of severe tinnitus, with almost complete loss of hearing, in a male, æt. 21. Drug treatment had proved valueless. Dr. Potter asked whether, in the opinion of members, this was a suitable case for removal of the cochlea or division of the auditory nerve.

This interesting question was discussed by the President and a large number of members, who were unanimously opposed to operation, because in this case the tinnitus, instead of being referred to one or both ears, was generalised over the whole head, and was therefore in all probability of cerebral origin. Dr. Potter concurred in this opinion.

DEAFNESS WITH NUMBNESS OF THE EAR.

Mr. ARTHUR CHEATLE read notes of a case of internal ear deafness of sudden onset and associated with a "dead feeling" in the ear of a woman of middle age. Mr. Cheatle attributed the numbness to an associated affection of the second and third cervical nerves. "Noises," lasting twenty or thirty minutes and followed by deafness, had come on after the patient had yawned seven or eight times. There had been no vertigo, the deafness persisted, but the tinnitus had become "occasional." Examination of the ear revealed nothing but marked nerve deafness.

ACUTE OTITIC CEREBRAL ABSCESS.

Mr. A. L. WHITEHEAD reported the case of a boy, æt. 14, who, having had double otorrhœa for twelve months was suddenly attacked by acute headache. When first seen headache had lasted twenty-four hours, drowsiness six hours, coma three hours. Both middle ears were filled with pus and granulations; both mastoids were tender. The radical operation was performed on both sides, and subsequently exploration of both temporo-sphenoid lobes, the latter with a negative result. The coma continued; thirty-six hours later an abscess in the right temporo-sphenoid lobe of the brain was found and drained. The patient recovered. Mr. Whitehead remarked on the comparative rarity of acute abscesses, and the difficulty of diagnosis and comparative frequency of acute extension of chronic abscesses.

A MODIFICATION OF THE RADICAL MASTOID OPERATION.

Mr. CHARLES HEATH read a short paper (founded upon an experience of 400 operations) on the restoration of hearing after removal of drum and ossicles by his modification of the radical mastoid operation for suppurative ear diseases.

The discussion on Mr. Heath's paper was deferred until the next meeting.

EXHIBITS.

Dr. ALBERT GRAY gave a lantern demonstration of the following specimens:—The human membranous labyrinth, showing (a) an accessory ampulla in the horizontal canal; (b) supernumerary otoliths or calcareous deposits in the labyrinth. The membranous labyrinth of the seal, showing (a) the large size of the organ; (b) the large otoliths. A section of the cochlea of the mouse. A section of the organ of Corti of the mole, showing the spiral arrangement of the nerve-termination at the base of the hair-cells. Section of the cochlea of the guinea-pig.

Mr. RICHARD LAKE exhibited an oto-masseur driven by a turbine (Ash) giving 2,000 strokes per minute.

In the evening the Annual Dinner, at which the President, Dr. Barr, presided, was held at the Trocadero Restaurant.

The principal guests were Sir Thomas Barlow, Sir Douglas Powell, Sir Felix Semon, Dr. Fredk. Roberts and Dr. Nestor Tirard.

In responding to the toast of the Otological Society, the President set a high ideal before the members; he hoped some day to see in working order a scheme of research in the pathology of ear disease, and to see established a central museum of otology to which all students would have access.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, January 1st, 1905.

CHRONIC APPENDICITIS.

THERE is a tendency to-day to consider appendicitis no longer as an acute malady commencing suddenly, but as a process essentially chronic, subject to acute symptoms of which the clinical expression is the "attack." It is in attentively examining the history of the patients that digestive troubles and pain can be discovered, which constitute the true prodroma of the appendicular attack.

Three orders of symptoms, says Dr. Wagon, exist in chronic appendicitis: pain, dyspeptic troubles, and certain phenomena resulting from chronic infection. The pain can be spontaneous or provoked, but rarely absent. In children it is seated in the umbilical region or on the right side of the umbilicus. It appears suddenly without prodroma while playing, or is provoked by some movement; the child stops, turns pale, and puts his hand on the painful spot. The pain only lasts a few seconds, and disappears without leaving any local tenderness. In the adult the seat of the pain varies, and is of little importance as a diagnostic. Sometimes dull, it presents a greater intensity on the right side. It can be found in the epigastric region, the lumbo-iliac region, in the left iliac fossa, and at the base of Scarpa's triangle. The pain, however, is never so intense as to make the patient cry out. Pain provoked by a gentle and deep pressure over the point of MacBurney is the most important and the most constant symptom; but, contrary to the received opinion, its absence at this point does not necessarily imply the absence of the appendicitis.

The digestive troubles are extremely variable. The most alarming are the acute phenomena of intestinal infection, with high fever, foetid diarrhoea, vomiting (sometimes), loaded tongue, foetid breath, which appears so frequently in the course of chronic appendicitis, particularly in children.

A very important phenomenon which is sufficient to give the idea of appendicitis, particularly in the adult, is that such patients digest certain foods with difficulty, always the same for each patient (meat, sauces, fatty foods); and the patients have remarked that the digestion of these foods always coincided with a return of the painful abdominal sensations. In certain cases vomiting is observed after meals—children especially suffer from this kind of dyspepsia. Constipation is very frequently observed. Patients suffering from chronic appendicitis frequently present

a facies characterised by anxious expression, sub-icteric tint, sunken eyes, pinched nose—phenomena depending on a certain state of congestion of the liver. The most frequent complication, as well as the most important, of chronic appendicitis is the acute attack.

As to the treatment of chronic appendicitis, it mainly consists in rest, régime, and a judicious employment of purgatives.

INCONTINENCE OF URINE IN CHILDREN.

Incontinence of urine is observed almost always in children from three to ten years old; some have it diurnally as well as nocturnally, but others, and they are the most numerous, urinate simply at night. According to M. Guinon, these children belong to the degenerate and neuropathic type. It can be said that the commencement of this neurosis is the hyphen between first and second childhood; it is the persistence of the habits of infancy, and results from derangement of the nerve centres. The trouble manifests itself by atony of the sphincter added to the spasmodic contraction of the muscle of the bladder, a veritable spasm, independent of the will. If such is the affection, an antagonist should be opposed; an anti-spasmodic must be chosen, and atropine is indicated in preference to belladonna, which is much less active, or to rhus aromanticus, which does not always succeed.

M. Guinon employs the following solution:—

Sulphate of atropine, 1 centigramme;
Water, 10 grammes.

For a child, *æt.* 6, five drops are given three times a day in a tablespoonful of sweetened water, and increased by one drop each time until 10 drops are reached, or 30 drops daily. This latter dose is maintained for two or three days to insure a complete cure.

In cases of very young children (two or three years) the initial dose is 2 drops three times a day, and increased in the same manner until 15 drops in the day are attained. As an adjuvant to the above treatment, which seldom fails, the wet sheet may be employed morning and evening for half an hour.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, December 31st, 1904.

At the Society for innere Medizin, Hr. Plehn spoke on

PSEUDO-LEUCÆMIA.

He said two distinct diseases were designated by this name, one with multiple tumours, in which peculiar polymorphous wandering cells participated. This disease had certainly nothing to do with true leucæmia. Then true lymphadenomata of homogeneous cells, the carriers of these tumours, and in the blood not the characteristic features of leucæmia, because a flooding of these blood cells had not yet taken place—a latent leucæmia. Under certain circumstances this feature remains limited to the bone marrow, and then occasionally the leucæmia remains latent until death. Then the disease was looked upon as pernicious anæmia, according to the behaviour of the blood. Sometimes, however, the leucæmia became manifest from the character of the blood in a few days, as Litten first pointed out. Benda also had occasionally found a symptom of pernicious anæmia in bone marrow. There were therefore many connecting links between leucæmia and pernicious anæmia. The speaker, in the case of leucæmia, had found the same iron reaction that was met with in pernicious anæmia. He then shortly sketched the clinical history of a case from which microscopic sections (shown) were taken. A patient, a middle-aged man, who had been ailing for months, attended Litten's polyclinic on September 5th, when the disease was diagnosed as lymphatic leucæmia. The proportion of red corpuscles to white was 1:12½; a week later the proportion was 1:350; some days later the changes of pernicious anæmia were found in the peripheral blood. Four weeks later the patient,

who had taken to bed, was admitted into the speaker's ward. Examination of the blood showed 9,375 white against 160,000 red blood corpuscles. The patient improved, the swelling of the spleen receded (perhaps from large doses of quinine), and in a week the red blood corpuscles had increased to a million. Then occurred rapid disappearance of red corpuscles, great increase of lymphocytosis (65,000, then hæmorrhage) and the patient died with symptoms of sepsis. There were streptococci in the blood.

Dr. Benda remarked that the symptoms had been very unusual. The large lymph gland tumours were absent, and the spleen had been much larger than was usual. The bone marrow showed an almost complete lymphoid change. Metastatic lymphomata were found in large numbers, especially in the liver and kidneys; the latter were swollen and so much filled with lymphomata that they looked almost white. There were numerous growths of lymphomata on the walls of the veins.

In the *Zeitsch f. N. Med.*, Dr. Metzger related a case of

MENSTRUAL JAUNDICE.

The patient was a healthy woman, æt. 45, therefore in the climacteric period, who shortly before commencement of a period or during it, regularly became jaundiced.

As regarded the connection between the menstrual process and the onset of jaundice, it was to be borne in mind that latent gall-stone trouble would react with an attack during menstruation, but in the case under notice there was no trace of gall-stone mischief. Senator, in explanation of his cases, had assumed a hyperæmia of the liver causing pressure on the bile-passages, and consequent stasis of bile. E. Pick thought it was a functional disturbance of the liver cells. The writer concludes that in his case the jaundice was caused by reflex contraction of the bile-passages.

DISCUSSION ON PHYSIOLOGICAL ALBUMINURIA.

In the discussion that followed Senator's address on the subject, Hr. Max Salomon said the subject had to be treated clinically, as to its diagnosis, its prognosis, and treatment. He could not agree with the view that when albuminuria appeared under certain conditions—after a hearty meal, fatiguing marches, cold bathing, &c.—it was of no pathological importance. He saw in it in any case a warning sign, and it behoved such patients as possessed it to avoid anything that could bring it on. It was plain that with them the kidneys were the seats of lesser resistance. He would not deny that such a condition could be recovered from, but at the time one could form no judgment as to whether they would recover or end in chronic nephritis. A case came to his own knowledge, in which a young medical man found occasional albumin in his urine, and consulting a medical friend was told that it was physiological. Much comforted, he went on as before. Some years later he thought of marrying, and not wishing to marry as an invalid, he consulted another physician, who also told him the albumin was physiological and harmless, and that he might marry with an easy mind. The gentleman did marry, and four or five years afterwards died of contracted kidney, leaving a wife and two children in straitened circumstances. The case spoke volumes. It taught us that albuminuria was not to be treated as a *quantité negligible*, but seriously, and it taught us that there was no such thing as a physiological albuminuria, but that every albuminuria was pathological.

Hr. Fürbringer had seen cases of complete recovery, one that of a medical man who had undergone severe and sudden shock, and whose urine contained 6 per cent. of albumin. Complete recovery took place within eight months.

Hr. L. Caspar had watched three cases for years, and in the end they all turned to chronic nephritis.

Hr. Benjamin had seen albumin in the urine of a girl two days before each period, and Klemperer had seen such cases.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, December 31st, 1904.

HARD TRAUMATIC ŒDEMA.

RUDOLF showed a case of hard traumatic œdema to the members of the Gesellschaft of some interest to practitioners. The patient got his left arm hurt, which swelled up, but after effusion it soon healed again. Fourteen days later he got the same arm injured again, which swelled, with pain, but did not go down as before. The skin is now red and thick all over the back of the hand and fingers, which prevents flexing of the fingers and hand, except with great pain. There is no fever, nor can any fracture or injury to bones be observed by the assistance of the Röntgen rays, neither can atrophy of the bone be discerned.

This morbid process in the tissues seems to have been first described, although known long before this time, in 1901, by Secrétan. Vulliet shortly after this time described the process as a diffuse, fibrous exudation in the subcutaneous cellular tissue, which lasted eight or twelve weeks.

Grunbaum recommended injecting thiosinamin combined with the hot-air application.

TUBERCULOUS CARRIES AND RONTGEN RAYS.

Freund next exhibited four cases which he was treating at his clinic with the Röntgen rays. The first was a girl about twelve years of age, with caries in the first phalanges of the index finger, which had existed for eleven years, and twice during this time the bone had been cleaned out, leaving a fistula along the bone $1\frac{1}{2}$ centimetre long, and 6 millimetres wide. The rays were concentrated on the fistula, with the result that after twelve applications the fistula healed completely up, and now assumes a normal appearance.

The other three cases were epithelioma of the face, which was first removed and the rays applied to the bottom of the wound, which healed up rapidly afterwards.

In the case of females, Freund volunteered the information that these were more susceptible to the rays than others, as the menses were rapidly induced, or if pregnant produced telangiectasis, which ought to be carefully guarded against in all our experiments.

Federn asked if this sensitive condition to the rays was more accentuated during the period, or did it affect the whole body throughout the period? Again, was it active only a short time before and during the menstrual period?

Freund replied that the action was greatly accentuated before the period, which might be induced by the fulness of the vessels, as was also the case in the gravid state. He had one case where telangiectasis occurred, although the rays had not been used during pregnancy, nor for some time before conception. He presumed this phenomenon was due to the rays having altered the blood-vessels, or varied the current in some way.

TUBERCULOUS PROTECTION.

Teleky referred to the different changes that have taken place in the treatment of tubercle within the last decennium, and concluded that in spite of the orthodox bacteriology on the subject, we had only got the length of prophylaxis of an international character. He summed up the treatment in three phrases—"Dispensaire anti-tuberculeux," personal comfort, and hygiene, with removal to a suitable sanatorium. Among the poor the latter was a necessary adjunct, as their home comforts were limited and their environment bad.

After relating a number of conditions necessary, he thought the benevolent societies and town councils of Austria were rivalling Belgium, France, and Germany in providing sanatoria and convalescent homes. Since Calmette commenced these institutions in Lille every country in Europe had followed the example

with surprising zeal and reputed success. In Vienna itself the Austrian "Hilfsverein" established its first effort in 1902; last year saw another of these benevolent institutions rise; and now we are promised another next year. The convalescent homes must be distinguished from the sanatoria, the latter for poor patients, where the disease is active, the former where no infection exists, or non-active. One family may have members in each institution under the patronage of the medical benevolent society which extends over the whole of Austria, but such institution sends its own servants to investigate the habits, status, and condition of the individual members before admission. This secures immunity from dangerous contacts, which is all important in the successful treatment of tubercle.

Escherich congratulated Teleky on the good work this guardian society had undertaken, which, according to his opinion, was the first and best treatment of tubercle.

The Operating Theatres.

GREAT NORTHERN HOSPITAL.

INGUINAL LAPAROTOMY IN AN INFANT.—Mr. PEYTON BEALE operated on a male infant, *æt.* 3 days, who had been admitted with a history of having passed nothing *per rectum* since birth. The child was very well nourished and, as far as external appearances went, perfectly developed. There was some distension of the abdomen. Upon making a rectal examination, the tip of the finger encountered a narrowing of the lower end of the sigmoid. The rectum was quite normal, and no diaphragm could be detected within it. It was considered probable that the case was one of arrested development of the colon. Mr. Beale had generally found that when there was a well-developed rectum present and the finger could be inserted to the full extent without encountering any obstruction, that an arrest of development of the transverse and descending colon, and very often of the cæcum and ascending as well, was present. He therefore advised the house surgeon, Mr. Alford, to perform a right inguinal colotomy. He did this and two or three coils of intestine distended with meconium presented; attached to one of these there was observed to be a fibrous band about a quarter of an inch in diameter, extending up towards the liver; and starting from this where it joined the distended intestine was a rudimentary vermiform appendix about an inch and a quarter long and about a sixth of an inch in diameter. A mesenteric stitch was passed beneath a loop of the distended intestines, the stitch being passed through all the layers of the abdominal wall and then drawn tight and tied under the loop of intestine. Mr. Alford then freely opened the intestine, and a large quantity of meconium escaped. The bowel was rapidly irrigated with hot sterilised water in order to clear it as much as possible and the wound dressed in the ordinary way. The operation only lasted a very few minutes; this was, of course, a matter of great importance in very young infants, and it was, Mr. Beale said, in these cases of colotomy, which had to be rapidly performed, that the mesenteric stitch was of special value. He considered that in performing colotomy in adults, it was always desirable to stitch each end of the protruding loop of intestine to the skin; prolapse was much more common in the case of the large than in the case of the small intestine.

The infant only survived ten or twelve hours, and *post-mortem* the conditions which were present were exactly as diagnosed.

ST. THOMAS'S HOSPITAL.

NEPHRECTOMY FOR CARCINOMA OF THE KIDNEY.—Mr. BATTLE operated on a very stout woman, *æt.* 52, who had been sent to him by Dr. McCarthy Morris for hæmaturia. The history of the case was as follows: The patient had enjoyed good health until nine weeks before admission, when she had been seized with severe pain in the left renal region, which ran downwards towards the bladder. Soon after the commencement of this attack of pain she had noticed blood in the urine, and although the pain subsided after a few hours, there had been blood in the urine constantly since that time. On admission, examination of the urine showed it to be darkly red in colour and to contain on microscopical examination numerous blood corpuscles with a few pus cells, but there was no evidence of abnormal cells. The left kidney could be felt on examination, and was larger than normal. The history appeared to point rather to calculus than to anything else, and it was proposed to examine her with X-rays, in order to assist the diagnosis, but the X-ray department said that the patient was too stout to give any reliable result. The kidney was explored through a lumbar incision; no stone could be felt on examination of the kidney from behind, and the only unusual condition ascertained was a fulness about the pelvis of the kidney. This was rather indefinite, and it was thought that it might be due to a deposit of fat about the hilum of the kidney, between the ureter and the vessels. An incision was therefore made in the kidney substance behind, and through this the forefinger was passed into the renal pelvis; no stone could be felt, but in its lower part there was a soft, cushiony, smooth projection, about the size of half a walnut; this, which was evidently new growth, was broken off with the finger and extracted with forceps; the base from which it had been removed bled rather readily, and the hæmorrhage was stopped by pressure. A portion of the growth evidently belonged to a larger mass involving the substance of the kidney, and was of a malignant nature; it was therefore decided to remove the kidney at once, and this was done, the pedicle and ureter being caught in the same clamp, and after excision of the kidney they were enclosed in one ligature of No. 4 silk. The growth, which was the size of a hen's egg, occupied the lower and anterior part of the kidney; it was soft and vascular, with a smooth, bossy surface. No enlarged glands could be felt. The operation was a difficult one, on account of the extreme stoutness of the patient, but she bore it well, and did not suffer much from shock. Mr. Battle said that in the absence of help from the X-ray department he did not think it was possible to come to a correct diagnosis in a case of hæmaturia commencing suddenly with severe pain only nine weeks before admission. In all cases of excessive hæmaturia of renal origin occurring in patients over middle age, the possibility of growth, he thought, must not be overlooked, and its duration will help very much in deciding whether it is of a malignant nature or otherwise. Some cases of renal calculus, he remarked, may cause hæmaturia without pain, although this is a most unusual occurrence; much depends upon various factors in the case, such as intermittence in the flow of blood, its amount, the duration of the symptom, and the effect of treatment or neglect of treatment.

In all probability in this case the attack of pain was caused by the passage of a blood clot, and was not due to obstruction of the ureter by growth, for the character of the piece which projected into the pelvis of the kidney negated any possibility of its acting as a valve.

A few days after the operation the amount of urine daily passed by the patient diminished to a few ounces, but at the end of ten days the remaining kidney was working well, and a normal quantity was being passed; the case has since progressed favourably.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, JANUARY 4, 1905.

THE HOSPITAL SUNDAY AND KING EDWARD'S FUNDS AND THE ROYAL ORTHOPÆDIC HOSPITAL.

It is natural that the various Hospital Funds should seek to exercise the power put into their hands by the great sums of money entrusted to them for distribution. No readier method of enforcing their views upon individual institutions could be imagined than that of the purse, by way of the bestowal or the withholding of grants. At the same time, the interests of the public demand that, in wielding this great power, the policy of the Funds should be clearly stated. Anything in the nature of an arbitrary and autocratic executive, which gives without stint to one and withholds without explanation from another charity, cannot be tolerated in the present democratic age. With all due respect to the transparent loftiness of aim and purity of purpose of the Hospital Sunday and the King Edward's Funds, we must insist that their administration partakes more of the irresponsible methods of a Russian bureau than of the typical British trust supported by the people, controlled by representatives of the public, and freely criticised by the press. We will now proceed to inquire how the influence of the Hospital Sunday and the King Edward's Funds has been brought to bear upon the Royal Orthopædic Hospital, formerly in Oxford Street, but recently

amalgamated with the National Orthopædic Hospital. It is difficult to obtain exact proof, as the Funds rarely furnish reasons for giving or withholding grants. The Royal Orthopædic, however, was considering the sale of site in 1898, and the Hospital Sunday Fund grant in that year sank to £52 10s. In 1899 the proposal to sell the site for £28,000 by Lord Wantage, as chairman, and Sir Walter Gilbey, as treasurer, was defeated by a party led by Mr. Harry Marks, now M.P. for the Thanet division. Soon afterwards, Mr. Marks became chairman, and then, curiously enough, suddenly reverted to the policy of sale. The grants of the Sunday Fund thereupon sprang from £52 in 1898 to £78, £95, £100, £134, £81, and £100 in successive years to 1904. Will the Sunday Fund say whether the decrease and increase of grants had any relation to the question of sale of site? The secretary of the Royal Orthopædic Hospital, in the *Hospital* for December 10th, 1904, denied that the Metropolitan Sunday Fund advised his hospital to sell its site. Against that statement we hold the definite assurance of a member of the deputation, consisting of the honorary solicitor, one of the surgeons, and the secretary, that the chairman of the Fund said in so many words that the hospital should be sold. In any case the general hostility of the Sunday Fund to small hospitals is no secret. That is freely admitted by Sir Henry Burdett who, in the *Hospital* for December 3rd, 1904, speaks of the “time the Hospital Sunday Fund urged that a sale was desirable.” On the whole, it seems clear enough that the Sunday Fund has all along approved the sale of the site, urged amalgamation, and influenced the Royal Orthopædic either by reducing or by increasing grants. As to the King Edward's Fund, there is no room for doubt. The first grant to the Royal Orthopædic was one of £61 5s. in 1897, about the time when the sale of the site was first seriously discussed. In 1899 a grant of £250 was made for “rebuilding and new site fund.” Next year a grant was refused, “last year's conditions being ignored.” In 1901 £200, and in 1902 £250 were awarded towards the discharge of existing debts. In 1903 a further £200 was given, with the note: “the committee view with satisfaction the amalgamation with the National Orthopædic Hospital.” Here, in the King's Fund, there was no hesitation in saying why grants were given or withheld—an outspoken practice that may be commended to the Metropolitan Sunday Fund. On the foregoing evidence we may reasonably assume that both the Funds in question urged the sale of the Royal Orthopædic site both directly by spoken and written word, and indirectly by the granting, or, more forcibly still, by the withholding of grants. The point is, could the Funds limit their responsibility to advice upon so vital a matter without full inquiry into the facts of the sale they were urging? Was that inquiry made? If so, where are the official minutes of the information on which the Funds acted? The sale was opposed by a small but

strong minority of the hospital governors, by the *Lancet*, and by THE MEDICAL PRESS AND CIRCULAR. What steps were taken to ascertain the grounds of this opposition before the Funds gave their powerful support to the sale? Had the Funds' wishes been followed in 1899 the hospital would have lost £12,000, as the minority forced the sale price up to £40,000, and claim it is worth £50,000. Sir Henry Burdett says it was the duty of the governors to secure "the highest obtainable price for the site." (a) "The Sunday Fund," he continues, "could have had nothing to do with the price or the value of the site, and their action must have been confined to an expression of opinion in favour of its being realised and a new site found elsewhere." The Funds' opinion, however, be it noted, ceased to be pious when backed by grants. It is our contention, before they brought pressure of such an extreme kind to bear upon the management of a hospital, they should have made an exhaustive inquiry into the circumstances of the case. It may seem to Sir Henry Burdett a small thing that a hospital should lose £12,000. Philanthropists are apt to think in large figures, a fact that the Prince of Wales has discovered in the wholesale annual waste going on yearly in London hospitals. Sir Henry Burdett has had a wide experience of City matters as secretary of the Stock Exchange and director of various companies. Perhaps he thinks the finances of the Royal Orthopædic Hospital are bound to be conducted on lines of absolute wisdom by a financier of the experience of Mr. Harry Marks, especially when aided by two such well-known City men as Mr. James Head and Major Ricarde-Seaver as trustees of the charity. The minority thought otherwise, and the soundness of their opinion has been abundantly confirmed by the enhanced value of £40,000, at which the site has been sold. They further thought that, if sold at all, the sale should have taken place at Tokenhouse Yard. Was that point—urged also by various medical journals—known to the Funds? The minority thought also that a site of such great and rapidly increasing value should have been let on lease. As a matter of fact, £1,400 a year was offered as a rental for one portion only of the site. By letting on lease a permanent income would have been secured to the charity, which would at the same time have kept an enormously valuable freehold endowment in their own possession instead of squandering its purchase money in bricks and mortar elsewhere. Was that aspect of the matter presented to the council of the Metropolitan and the King Edward's Funds before they urged the sale? Did they know and not care, or did they not know and not care? Anyway, the public is entitled to learn the methods of procedure adopted by the Funds in such weighty matters. It is shameful enough that medical charities should be damaged by irresponsible amateurishness. It is a thousand times worse, however, if public trusts are to be allowed to set up as auto-

cratic bodies, entitled to play fast and loose with the properties, the prospects, and the reputations of small hospitals.

TUBERCULOSIS IN IRELAND.

IN matters of public health it is curious how difficult it is to focus the attention of the public where it can prove of any use. A few years ago, owing in great part to the personal interest shown by the King, it is true that much interest was roused in the subject of the prevention of tuberculosis, and branches of the National Association sprang up all over the country. We fear, however, that the interest of the laity was of a temporary sort, and that, like any other fashion, it has now veered into other quarters where it is of much less service. For instance, one can hardly take up a daily paper without coming on paragraphs dealing with researches into the causation and therapeutics of malignant disease, a subject which is precisely at the stage where it can only be safely dealt with by men of science. We only wish that half the energy which is now dissipated in idle curiosity as to alleged cancer cures were spent in rational work for the prevention of tuberculous disease. It is constantly demanded of medical men and men of science to explain the causes of this, that, or the other disease, but when this is done and, the public is furnished, as is the case with tuberculosis, with methods for the prevention, if not for the cure, of the disease, then but little use is made of the knowledge. We are led to these remarks by the fact that the Dublin Branch of the National Association for the Prevention of Tuberculosis, in a city of over a quarter of a million inhabitants, in spite of the energetic exertions of the honorary officers and committee, enrolled only three new life-members during the year, and that it contains in all only seventy-five paying members. And, indeed, Dublin, in this respect, is only typical of the lack of interest all over the Kingdom in this overwhelmingly important subject. It is only a few weeks since the Council in London was forced to appeal for funds to the public in a letter to the papers, in which it was stated that "the apathy of the public and the inertia of authorities charged with the maintenance and preservation of the public health have to be overcome. The further work of the Association will be seriously curtailed unless further subscriptions to the funds be forthcoming." It is a matter for rejoicing, however, that although the National Association is not supported as it deserves, much is being done to reduce the mortality from tuberculosis. In England and Scotland there has been, during the past forty years, a steady decrease in this mortality, but in Ireland the rate is stationary. In Great Britain the public bodies are gradually recognising their responsibility and duties in the matter, but in Ireland, except the educational work, done for the most part by the agency of the National Association, nothing has been done. The public bodies, with one or two exceptions, have not moved. The Dublin Corporation has distinguished

(a) *Hospital*, December 2nd, 1904, p. 180.

itself especially by its stony deafness to the suggestions alike of its own Public Health Committee and of the medical profession. We commented adversely some weeks ago on their refusal to appoint a City Bacteriologist to give assistance to practitioners in matters of diagnosis, and we are glad to see that the Annual Report of the Dublin Branch of the National Association raises the same point. Cork and Belfast, luckily, are far ahead of Dublin in dealing with tuberculous disease. An arrangement between the city of Cork and the various district councils has been come to by which a sanatorium for the consumptive poor of the city and county will shortly be established. In Belfast the Board of Guardians is about to remove to the country the two or three hundred consumptive patients at present in the union infirmary. We are glad to notice that the interest of the various religious bodies in Ireland has been roused in the subject of tuberculous disease, and at the recent meetings of the General Synod of the Church of Ireland, of the General Assembly of the Presbyterian Church, and of the Methodist Conference, resolutions on the question were adopted. The Dublin Branch of the National Association continues its excellent educative work on the community at large, and it must not be discouraged if the results obtained are not as rich as was hoped would be the case some years ago. Public bodies are hard to move, for they wait till a strong public opinion is formed, and it is only by such work as the Dublin Branch has taken in hand that this end is to be attained.

Notes on Current Topics.

Mr. Jonathan Hutchinson and Titular Honours.

It is said that henceforward the New Year's honours list will cease. The recurrence of the familiar season, however, reminds us of the curious absence of titular distinction as regards one of the most distinguished figures in the modern British world of medicine. It may be that, like John Bright and William Ewart Gladstone, Mr. Jonathan Hutchinson has declined an honour which does not appeal to his philosophical mind, and prefers that his name should go down as a commoner to posterity, whither it certainly will go. There are public aspects of the question, however, which should render the views of a particular individual to some extent amenable to more general interests. In the case of a medical man the bestowal of titular honours has a peculiar significance, as it usually recognises the distinguished work of a man eminent in a noble and humane profession, where the average reward is scanty. The most conspicuous honour of the kind is obviously that of the peerage bestowed upon Lord Lister. It is likely that his name will live for ever in the history of mankind as one of the greatest benefactors that the human race has ever known. It is right and fitting, therefore, that Lister should be recognised by

one of the highest titular distinctions available in our social system. On looking through the list of medical baronetcies and knighthoods, however, it is remarkable how many of them have been bestowed upon obscure individuals whose names are not widely familiar in their own, and will certainly never survive the cycle of a succeeding generation. Some of these titles have been given for military or naval services, and many have been given to presidents of colleges or provincial schools, while others, again, have been bestowed upon medical men whose duties have brought them into contact with Court circles. In any ideal scheme of distribution the test of titular worth would not unreasonably be made to depend upon the scientific standing and achievements of the individual. Applying that test, there is no untitled medical man in London more entitled by his sheer scientific merits to titular honour than Mr. Jonathan Hutchinson. Year after year we have seen his name omitted from the lists with a feeling of surprise and chagrin, and a growing conviction that the only possible explanation of this unaccountable omission was the express objection of Mr. Hutchinson himself to any such honour. Year after year medical knights and baronets have been created who were, from the point of view of scientific comparison, unfitted to loosen the latchet of the shoe of one of the most philosophical surgeons of the last half century. We venture to draw the attention of Mr. Balfour's Government and of His Majesty to what appears to have been an unaccountable oversight. If Mr. Jonathan Hutchinson has declined titular honour we certainly think that fact should be officially announced, or else the whole system of bestowal of such honours will sustain a most damaging blot upon its reputation.

The Examinations of the Central Midwives' Board.

We are glad to see that the Privy Council has referred back to the Central Midwives' Board the scheme of examinations which the Board submitted to the Council for approval. The Board, or rather that portion of it which has so far apparently acted whenever possible in opposition to the medical profession, decided to appoint examiners other than registered medical practitioners to examine, and, as we are informed, gave as a reason for this curious action that it would be well to have examiners who could examine in bed-making. The Privy Council has, however, put a stop to the absurd anomaly which would have rendered it possible, and, indeed, probable, for some half-trained midwife to sit in judgment on the teaching of registered general practitioners in all such medical matters as the scheme of examination included. The Privy Council considers that the examiners appointed by the Central Midwives' Board should be duly qualified medical practitioners, and that it should be optional to the examiners, when they thought fit, with the consent of the Board, to employ, for certain parts of the

examination, properly qualified women who were not medical practitioners. We congratulate Sir William J. Sinclair and those of his colleagues who opposed the Central Midwives' Board on this matter on the success of their opposition. Some little time ago, we recorded the fact that the dispute between the authorities of the Rotunda Hospital and the Central Midwives' Board had been satisfactorily arranged, and that in future nurses trained at the Rotunda Hospital would be allowed to present themselves for the examination of the Board, and we are now glad to see that the Coombe Hospital has been similarly recognised. Truly, the ways of the Central Midwives' Board are past comprehension! In the past, its method of procedure has been farcical and its actions ludicrous; it has ridden for a fall, and it has received one. Will it, in future, conduct its deliberations in, and allow its actions to be governed by, a judicial spirit? We hope so.

Medico-Legal Experimentation.

THE mysterious death of M. Syveton, following so closely upon his assault on General von André and the uproar created by his extraordinary conduct, has given rise to profound sensation in France. The various theories of homicide, suicide, and accident each have their advocates, but probably the real truth will be elicited by the inquiry now being instituted by the *juge d'instruction*. M. Syveton, it will be remembered, was found dead in his study. His body bore no marks of violence, and circumstances pointed to death having been due to coal gas, or carbonic oxide, poisoning. Madame Syveton advanced the theory that her husband had taken his own life, either by leaving the tap of a gas-stove, which he had in the room, turned on whilst he sat at his table, or by deliberately inhaling the gas as it came from the stove. It therefore became important to find out if either or both of these methods were feasible, and, if feasible, likely to be effective. As both of them suggested practical difficulties which seemed to negative the idea of suicide, appeal was made to Dr. Ogier, and he decided to put the matter to a practical test. A dog was taken and tied to the stove in such a manner that he inhaled the gas directly from the open burners, whilst two guinea-pigs were left free to run about the room. The dog made frantic struggles to get free, and did not die for nearly an hour, whilst the guinea-pigs were still alive, although unconscious at the end of that time. This evidence would seem strongly against the idea of suicide, for it would practically negative the idea that M. Syveton died while sitting in a chair away from the stove, and it would still more strongly militate against the theory that he held his head over the jet and inhaled the gas directly. Only the most determined suicide would hold himself in a strained position for nearly an hour in order to destroy his life. Whatever the eventual upshot of the inquiry may be, the evidence obtained by the experiments will be of great help to the *juge* in coming to a right conclusion,

and thus demonstrate—if demonstration were needed—the utility of experimentation on animals in medico-legal work. We tremble to think of the outcry which such an experiment would produce if performed in this country—to say nothing of it being directly contravened by the existing state of the law.

Murderer Feigning Insanity.

IT is somewhat strange that criminals when arrested for murder do not more often endeavour to evade the penalty of their crime by feigning insanity. Probably their ignorance of the real symptoms and signs of mental disease prevents them from trying to practise a deception which, if successfully carried through, would substitute a life of comparative ease for the certainty of death. Wagner (a) describes a case in which the patient, a man aged thirty-two, who had murdered his wife, pretended to be insane, and with great ability kept up the fraud for eighteen months. He appeared morose at some times and incoherent at others, and to these psychical manifestations he added certain physical ones—inability to walk, coarse tremor of the leg, and Rombergism. Although tried and convicted, he was never caught off his guard for a moment, and when the state of his mind was subsequently inquired into by a committee of experts, he wore such an imbecile expression and behaved so strangely that he might possibly have got off had not Wagner suggested that the effect of an anæsthetic should be tried. As the ether was being administered, he began to talk in a loud voice, although previously he had only appeared able to whisper, and his language was not only coherent but profane and abusive. When consciousness was fully abolished he was placed on his feet and allowed to come round in the vertical position, and then, before he was thoroughly aware of his surroundings, he was assisted to make a few steps, and then left. He continued walking, placing his feet squarely on the ground, and showed no signs of the tremor of the legs that had been constant before. The prisoner afterwards confessed that he had been malingering, and added that the strain for eighteen months had been so awful that he would rather die than endure it longer.

A Lady Dentist.

DENTISTRY would seem to be the Cinderella of the professions, so far as women are concerned. Medicine they have eagerly embraced, the ministry possesses at least one lady pastor, and the bar is only recruited from the ranks of the male sex because it churlishly refuses to entertain angels un-awares. But this stigma has now been removed—not, unfortunately, in this country—by the recent success of the Countess Helene von Schweintz in the final examination in dental surgery at Berlin. It is somewhat remarkable that a calling which demands so much neatness of hand and manual dexterity should have hitherto exercised too little

(a) *Med. News*, November 19th, 1904.

attraction for the newer womanhood, especially when many are entering paths where the qualities which generally characterise women are but little advantageous. A lady dentist in this country would be pretty sure of a *clientèle* of the curious, just as the earlier women doctors are said to have had a good many patients who came to see how they would act and what they would say. But, we fear, one can hardly hope to start with a Countess as the first female dental surgeon. Medicine has not yet drawn to its study a peer of the realm, much less a peeress. In Germany, however, things are different. There the nobility are considerably more numerous than here, and considerably less well off. Quite a number of barons are in practice as physicians, and there are at least two princes who have devoted themselves to ophthalmology. The enterprising Countess, therefore, will not find herself entirely cut off from "her own people."

Campaign Against Tubercle in the United States.

It is perhaps due to the fact that tuberculous disease does not figure so largely in the death statistics in America as in this country that our neighbours have been somewhat behindhand in the formation of a National Association for the Prevention of Tuberculosis. It is true, however, that preventive measures are practised in many of the States in a much more efficient manner than we are accustomed to. For instance, the laws against spitting in public places are much more stringent than has been found practicable at home, and thus a prolific method of spreading infection is annulled. Again, in many American cities, the public health authorities deal with tubercle and other infective diseases in the most efficient manner. Expert aid is at hand for the early diagnosis of tuberculous disease by bacterioscopic methods, and rigorous disinfection of premises is practised. Nevertheless, there is still plenty of educative work for a Preventive Association to perform, and the newly-formed body, whose executive contains the leading men in the profession in America, will, if it keeps to the programme sketched out at the inaugural meeting, find its hands full. Among the items mentioned are the erection of sanatoria and isolation hospitals, the promulgation of special legislation, the education of local Boards of Health, and a propaganda to the people by means of pamphlets, popular lectures, and articles in the press.

A Bone-Setting Romance.

THE remote districts of the Lowlands, which a few months ago sprang into unenviable notoriety from the fact that three bone-setters of extraordinary fame had elected to practise in them, seem to have lost their proud pre-eminence, for one now hears of these experts popping up in all sorts of different places. One of them has found an anchorage in Bond Street, and here he is daily being interviewed by halting patients and by

minor journalists. The visits of two of these happened to coincide—doubtless by chance—the other day, and the result was that an interesting account of the consultation and its results found its way into one of the leading morning papers. The patient was a charming lady who had been stricken with paralysis of one side of the body five years ago, but later the palsy took the curious course of "settling in both her feet." The medical treatment for this extraordinary malady seems to have been an unusual one for paralysis of the feet, namely, the application of iron supports to the outsides of the legs; anyhow, thus equipped, the paralysed lady was able to walk about. A lover in the background completed the picture, but for all the lover's faithfulness the iron supports acted as an insuperable bar to the legitimate consummation of his aspirations. This pretty romance only needed the bone-setter to act the part of the fairy queen, and in Bond Street the bone-setter was found. A few magic manipulations of the paralysed feet—the irons were discarded, and the lady walked with springy gait. The lover beamed, the journalist wrote, and the bone-setter doubtless pocketed his fee. Thus all ended happily. The interview could not be prolonged as a large number of patients were waiting to see the bone-setter. How the rest of the suffering and doubtless opulent crowd fared, however, is not recorded.

Pathology at Oxford.

WE are glad to observe that the importance of making proper provision for the teaching of pathology at Oxford is not likely to be overlooked. It will be remembered that, when the Regius Professorship of Medicine fell vacant, it was proposed to appoint the Reader in Pathology to the vacant chair, as the University was unable from any other source to make due provision for the maintenance of the pathological department. The proposal, however, met with strong objections from a large and influential body of Oxford graduates, and was finally abandoned, and, as everyone knows, the Chair of Medicine was offered to Dr. Osler. The problem of establishing the teaching of pathology on a proper basis still remains. The University chest professes itself unable to furnish funds at all adequate to the demands of the situation, or sufficient to retain the services of the present distinguished Reader. Temporary help has been given by the Rhodes Trustees, who are granting a sum of £200 a year for five years on the condition that Dr. Ritchie remains in the Readership. This timely help should allow some means to be devised to meet the situation. A meeting of Oxford men was held in London before Christmas under the chairmanship of Sir William Church, when resolutions were adopted in favour of starting an endowment fund for the permanent support of a pathological department at Oxford, and of pressing its claims for fuller recognition from the University authorities. A strong executive committee has been appointed, and some large subscriptions have been already promised. We trust that the effort

thus inaugurated by pious sons of the University will receive support not merely from Oxford men, but from the public.

Secret Commissions in Canada.

WE commented in a recent number (a) on the system of underhand commission or "grafts" which is a subject of discussion in the States. We learn from a Canadian contemporary (b) that the same noxious practice is creeping into the Dominion, and in Toronto a particularly offensive trick has just been brought before the public. A well-known physician of that city, Dr. MacCallum, received a note from the principal of an important ladies' college asking for his medical attention to one of the pupils, "subject to the usual condition that a discount of 10 per cent. is deducted by the College off fees charged to the pupils." He very properly refused to accede to any such conditions, and followed up his refusal by bringing the correspondence before the profession in Toronto, and before the College of Physicians and Surgeons of Ontario. The unpleasant part of the thing is not the impudent attempt to bribe Dr. MacCallum, but the fact that other medical men have been found who are ready to attend pupils at the College on the proposed conditions.

M. Doyen and Cancer.

FROM the highly sensational paragraphs which have appeared in the lay papers during the past few weeks, many have been led to believe that M. Doyen's views as to the causation and cure of cancer had been upheld by competent authorities. It was freely stated that the committee of experts appointed to inquire into the matter had sent in their report, and that it was conclusive on the side of M. Doyen. We learn, however, from M. Doyen's own statement to the Société de Chirurgie, what we had indeed somewhat suspected, that the matter is still far from being a *chose jugée*. The Committee's report has not yet been drawn up, nor is it likely to be so for a considerable time. One of its members, however, M. Metchnikoff, who was conducting the investigations from the bacteriological standpoint, has sent in a preliminary report. This very guarded document states that in several cases he has obtained from fragments of cancerous tumours pure cultures of an organism identical with the "micrococcus neoformans" described by M. Doyen. In other cases, however, though in a smaller number, he failed to find the organism. Of its specificity he is unable to say anything until a much longer period has been occupied in experimental work, and the same remark is made of its pathogenicity towards animals. So far, M. Metchnikoff speaks *ex cathedra* as a bacteriologist. Disclaiming, however, any right to express any opinion on clinical grounds, he, nevertheless, admits that he has "received the impression that several patients attacked by very grave cancer have been benefited

by the injections of M. Doyen." It might have been more prudent of M. Metchnikoff to have left all expression of opinion on clinical matters to his colleagues, but it will be seen that as yet matters have not been really advanced, except in so far as the existence of M. Doyen's coccus is established.

Laundry Hygiene.

THE way in which soiled linen goes through the laundry leaves little to be desired, however much it may be criticised. The accusation of wilful destruction called forth by the return of collars and cuffs, not to mention other raiment, in a barely recognisable condition, may now and then appear to be justifiable, but surely the spoiling of one's linen may be borne with a certain amount of resignation, nay, even with cheerfulness, when it is accompanied with the manifold advantages of a sepsis? Modern sanitation has undoubtedly effected great reforms in the management and conduct of public laundries in large cities, and it is comforting to reflect upon the reasonable safety and immunity from infectious disease enjoyed by customers. What though the linen does not possess quite that snowy whiteness such as is obtained from the drying-grounds of the country hill-side, may it not almost be worn by an "up-to-date" operating surgeon without any qualms of conscience? It might be supposed, however, that it is another matter with the laundry employes themselves. Theirs is all the unpleasant part of the business, and one which is commonly believed to predispose to divers affections, such as rheumatism, varicose veins, and eczema. With the object of ascertaining if such is really the case, Dr. Ira S. Wile (a) sent round a circular letter to the proprietors of a number of laundries, asking certain questions regarding the prevalence of disease among the workers. The answers he obtained show conclusively that there is no more illness among laundry employes than is the case with other workers in factories or shops. It is somewhat remarkable that in this experience not a single case of acute specific disease was contracted through handling soiled linen, which, however, was not received from places where contagious disease was known to exist. Tuberculosis was not more common than elsewhere. That "starching was the best employment for consumptives" was a view expressed by one scientist.

Loretto Dress for Boys.

THOUGH the coat does not make the gentleman yet a flannel shirt may be the making of a school-boy, at least, such is the deliberate opinion of Mr. E. N. Marshall, M.A., the headmaster of the Kingston-on-Thames Grammar School. Having spent seven years at Loretto, this worthy pedagogue was much struck by the fact that the average physique of the boys was far superior to that observed at any other public school, especially with regard to chest measurement and develop-

(a) THE MEDICAL PRESS AND CIRCULAR, December 21st, 1904.
(b) Canadian Journ. of Med. and Surg., December, 1904.

(a) Med. News, December 3rd, 1904.

ment of the limbs. Sixty per cent. of the scholars were English. The distinctive dress worn by the boys is believed to be the chief cause of their increased physical well-being. This consists in flannel shirts with collars of the same material, and flannel or tweed breeches, according to the season. The waistcoat is altogether discarded. The late Dr. Almond, founder of the school, noticed that within three months of the rejection of the latter garment an increase in the circumference of the chest was observed in nearly all cases. Combined with this costume, every encouragement is given to the boys to indulge in all forms of sport and physical exercises. Mr. Marshall has communicated with the parents of his pupils upon the subject of rational dress, advocating the adoption of the Loretto system at Kingston. There is no doubt that much of the clothing of the present day, both for children and adults, is at once both unsuitable and unhygienic. Motives of sentiment cannot be allowed to interfere with the growth and physical progress of the rising generation, and a costume which is reasonable and neither ludicrous nor ill-adapted to the movements of the body should certainly become popular. To endeavour to build up a coming race of giants by attention to collars and waistcoats, however, is to put the horse before the cart with a vengeance.

The Metropolitan Hospital Sunday Fund and Mr. Stephen Coleridge.

THE letter from the Hon. Sydney Holland published in our last issue suggests some serious considerations as regards the policy of the distributing funds and the medical charities. Here is a private gentleman, of the highest honour and integrity, the chairman of one of the greatest medical charities in the world, who feels constrained, according to his own admission, to shield the institution over which he presides from outside criticism by refusing a proffered subscription. Surely the methods of the London Hospital with regard to the disposal of its huge finances are not so weak and feeble as to be unable to withstand the wholesome breath of public criticism? If there be nothing to hide, why shrink from the questions of the Hon. Stephen Coleridge or any other man, be he crank, philosopher, knave, fool, or idiot? The Metropolitan Hospital Sunday Fund has taken upon itself to administer discipline to small hospitals, to say that under pain of loss or diminution of grants the hospital shall be rebuilt or amalgamated or what-not. Now let the Fund turn to the larger hospitals and first let it make up its mind definitely whether the London Hospital was or was not justified in spending £6,000 on a sports ground for students. That is Mr. Coleridge's question, and he has a right to be answered. Either the Hospital Sunday Fund has or has not a definite policy on the point. In any case, Mr. Sydney Holland, whose hospital draws a huge sum from the Sunday Fund, does not seem the right man to represent the views of the Fund. He is an interested party in the discussion.

Honours to Members of the Medical Profession in 1904.

It is interesting at the opening of 1905 to recall the honours that have been bestowed upon medical men during the past year. The July list of birthday honours included knightships to Dr. Thomas Stevenson, Analyst to the Home Office, Dr. Constantine Holman, best known in connection with the British Medical Benevolent Fund and Epsom College, and Mr. Kendal Franks, C.B., the Irish and South African surgeon. Several decorations were awarded in commemoration of the jubilee of the Crimean War. Among the recipients were Surgeon Thomas Ligertwood, who was made a Companion of the Bath in the Military Division. He served in the Crimea at Alma, Inkerman, and Sevastopol. Among the new Knight Commanders of the same Order were Deputy-Surgeon-General James Howard Thornton, I.M.S., C.B., and Surgeon-General Edmond Townsend, A.M.S., C.B., C.M.G. Surgeon-General William James Fawcett, A.M.S., was made a C.B., Military Division, and Hon. Colonel John Edward Squire, a C.B., Civil Division. Mr. Bolton Glanvill Corney, M.R.C.S.Eng., Chief Medical Officer of the Colonial Government at Fiji, was appointed a Companion of the Imperial Service Order. The November list of birthday honours bestowed the honour of knighthood upon Mr. Charles H. Marriott, Surgeon to the Leicester Infirmary; Mr. Shirley F. Murphy, Medical Officer of Health to the County of London; Professor William Japp Sinclair, Professor of Obstetrics at the University of Manchester; and Major Allan Perry, R.A.M.C., Principal Civil Medical Officer of Ceylon.

Medical Receptions by Public Performers.

AT present there is in Glasgow one Captain Vetrico, who styles himself the "poison-proof man," giving exhibitions in one of the places of entertainment of his ability to swallow lethal doses of certain poisons, such as strychnine, phosphorus, and so on, with apparent impunity. With these we are told he varies his *menu* by eating glass and flower-pots! Before he made his first public appearance, a number of medical men responded to his invitation to meet him in the Windsor Hotel, where he swallowed half a grain of strychnine in their presence, and also, we are told, partook in quick succession of considerable doses of Paris green, blue indigo, verdigris and so on without evil effects. This demonstration, we are further told, concluded by Captain Vetrico eating a considerable portion of a stick of phosphorus. He invites medical men to bring their own poison. A letter appeared in the *Glasgow Herald* pointing out the responsibility resting with any medical man, from a medico-legal standpoint, who should, in the event of this man's death, have supplied him with the poison. We think any doctor who procured for this man any of the recognised deadly poisons would occupy an unenviable position in the event of the man's death, and we most unhesitatingly say that life to him is always

peculiarly precarious. Recently another performer, who appeared as a hypnotist in one of the music-halls of the city, issued invitations to members of the medical profession. Evidently a number had accepted the invitation, as it was immediately announced that a large number of medical men had patronised his exhibition. Clearly members of the profession ought to exercise great discrimination in accepting such invitations, as the motive is perfectly apparent. In the case of the "poison-proof man" it is not one, we think, that ought to be encouraged with the semblance of professional approval, for it is an exhibition that can be neither elevating nor entertaining. We are in complete agreement with the *Glasgow Herald* when it said, in referring to this so-called entertainment, that "it is open to question whether a man has any right to toy with death" in that fashion.

THE attention of our readers will be doubtless arrested by the unusual number of deaths that have recently taken place in the profession. One remarkable fact is the large proportion of sudden deaths due to disease or accident. A perusal of our obituary columns of this week will bring the latter fact into prominence. Many of the recent losses have been those of distinguished men in the provinces as well as the metropolis, some of them of an old-fashioned, sterling type, of social and scientific worthiness that is by no means always to be found in the present generation.

PERSONAL.

WE are informed by the War Office that the King has been pleased to approve the appointment of Lieut.-Colonel A. Keogh, M.D., C.B., Deputy Director-General, Army Medical Service, to be Director-General, Army Medical Service, vice Surgeon-General Sir W. Taylor, M.D., K.C.B., K.H.P., retired.

SIR WILLIAM BROADBENT will give the Introductory Lecture to the spring course of Post-Graduate Lectures and Demonstrations held in connection with the Mount Vernon Hospital for Consumption and Diseases of the Chest, at the Central Out-patient Department, 7, Fitzroy Square, on Thursday, January 19th, at 5 p.m., the subject of the address being "The Examination of the Heart and What May be Learned from It."

DR. WILLIAM ST. CLAIR SYMMERS, M.B., has been appointed to the Musgrave Professorship of Pathology in the Queen's College, Belfast, vice Professor Lorraine Smith.

DR. WILLIAM GIBSON, Medical Officer of Health for the burgh of Campbeltown, was presented last week with a public testimonial, consisting of a cheque for £360 and a lounge chair, with silver salver and tea service for Mrs. Gibson, on the attainment of his fiftieth year of professional life in Campbeltown.

DR. FRED J. SCRIMGEOUR, Dundee, has been appointed to the responsible position of colleague and successor to Dr. Vartan, the well-known Scotch missionary at Nazareth.

THE Ameer of Afghanistan having applied to the Government of India for the services of a British officer to take medical charge of his household, the appointment has been approved of Major H. F. Cleveland, Indian Medical Service. Major Cleveland takes up

his residence at Kabul with a staff of native subordinates, but will retain his position in the Indian Service.

IT is announced that the new headquarters of the Manchester companies of the Royal Army Medical Corps (Volunteers) will be opened on Saturday, January 7th, by Major General M'Kinnon, Director-General of Auxiliary Forces.

DR. ANDREAS VISCHER, assistant in the surgical clinic of the University of Basle, will go out to Urfa in Asia Minor, as German medical missionary in charge of the hospital there.

THE President of the Board of Education has appointed Dr. Norman Moore, M.D., F.R.C.P., to be a member of the Consultative Committee of the Board of Education, vice Professor Bertram C. A. Windle, M.D., F.R.S., who has resigned his membership upon appointment as President of Queen's College, Cork.

MR. JOHN HENRY SALTER, J.P., surgeon, Tolleshunt D'Arcy, has been appointed to the office of Deputy-Provincial Grand Master, in the room of the late Mr. Claude E. Egerton Green.

Special Correspondence.

[FROM OUR OWN CORRESPONDENTS.]

SCOTLAND.

CONSUMPTIVE HOMES. BRIDGE OF WEIR.—This is part of the work instituted, and for long carried on by the late Mr. and Mrs. Quarrier, both recently deceased, and it may be said of both, they did noble service in their lifetime. An appeal by Miss Quarrier appears in the newspapers, from which we gather that the eighty beds in two blocks of buildings continue to be fully occupied, and many patients are constantly waiting for admission. It is proposed to begin the building of a third block to accommodate other forty patients; £8,500 of the £10,000 required has been subscribed. It is stated that about £20 per day is required for the daily needs of the consumption part of the work. Roughly, it works out at something approaching £2 per week for each patient. We understand the diet is generous, and therefore costly, and we think the greatest care should be taken to see that the patients assimilate the food which they are required to swallow, and we say this advisedly, as it is within our knowledge that some patients adopt expedients by which they escape taking the required amount of food allotted them. The work being done is very good, but we are of those who think that some economy should be exercised in this direction. Then again, it would be well if some of those patients who are dismissed, cured or improved, could be watched for some time afterwards, as with their altered environment to stuffy rooms and spare or perhaps starvation diet, compared with what they were getting in the Homes, a relapse is very apt to take place. We say this because we know of cases where patients were dismissed very much improved—not cured—and where relapse and death ultimately followed. We are informed that some of the patients now pay whole or partial board, as far as their circumstances will allow.

GOVAN MEDICAL DEFENCE ASSOCIATION.—Some short time ago, at least three-fourths of the medical men of Govan, near Glasgow, formed themselves into the above Association for the purpose of conserving their interests and improving their ethical and professional attitude towards one another. Their aim seems in a fair way of being realised, as there was held recently a meeting of the members of the Association to present Dr. Wilson, the President, with a tangible and valuable token of their appreciation of his services. Dr. James Barras made the presentation, and in doing so he said the Association had done good work in raising the minimum visiting fee to what it was in an adjoining district. Dr. Wilson (President) in a speech enlivened

by some pawky humour, said that the ordinary Govan man was not overburdened with generosity, but that he was "not a bad sort after all," and just as he wished to get his pound of flesh, so the medical man had a right to his. He went on to explain that the society had been formed to imbue the Govan working-man with a true sense of the fact that the medical men of Govan had some rights to conserve. He would tell the working-man a few things. He should not have a child taken ill in the morning and not send for a doctor till near midnight, and he was not to run from one doctor to the other, and not pay any of them. When he changed his address he should go and tell his doctor where he had removed to, especially if he owed his doctor a nice little bill. And he should not hold to the belief, which seemed to be very common, that a doctor was bound to come at once when called upon. This was not so, unless the fee was forthcoming. The evening finished very pleasantly with social intercourse, the general tone of the meeting showing that the members were on the best of terms with each other, and were united in striving to advance the interests of the Govan Medical Defence Association.

PRESENTATION TO DR. GEORGE HALKET, GLASGOW.—On the occasion of his resigning his position as Surgeon to Court Royal Thistle, A.O.F., Dr. Halket has just been made the recipient of an illuminated address and a study clock, with a beautiful silver rose bowl for Mrs. Halket, in appreciation of his valuable services extending over the long period of 26 years as medical officer. Dr. Halket, along with Dr. I. Stuart Nairne, is one of the original members on the staff of the Samaritan Hospital for Women, and we understand he is going to devote more of his time now to the work of the hospital.

PRESENTATION TO DR. GIBSON, CAMPBELTOWN.—Dr. William Gibson, medical officer of the burgh of Campbeltown, on the attainment of the fiftieth anniversary of his professional life in the district, was presented with a public testimonial in the Town Buildings on December 27th. The testimonial took the form of a cheque for £360, a lounging chair, a silver salver, and a silver tea service, and the presentation was made by ex-Provost Greenlees. Dr. Gibson is to be congratulated on the fact that after fifty years of arduous work he still feels able to continue his duties, and wishes to go on with his work.

CONTRAVENTION OF PUBLIC HEALTH ACT IN EDINBURGH.—A modified fine of 10s. was imposed on a man the other day for having conveyed his child, suffering from membranous croup, to the Fever Hospital in a cab. It seems that the doctor who examined the child did not come to any definite diagnosis but expressed the opinion that the child should be taken to a hospital or placed under observation. The accused then became alarmed and conveyed the child in the manner stated to the hospital. In the case in question there seems little doubt that the fine was deservedly imposed, and that the child ought to have been removed in a proper vehicle. But at the same time the machinery for transferring patients to the Edinburgh City Hospital is not all that can be desired in one respect, *viz.*, that it is practically extremely difficult to get patients removed after the public health office is closed for the day. The obvious solution would seem to be to allow notifications for removal of urgent cases during the evening and night to be accepted at the Fever Hospital; but this is not done, and a medical practitioner called in the evening to a case, say of diphtheria, where tracheotomy will probably be required within a few hours' time, has perforce to delay taking steps for its removal till the following morning. This has frequently been made the subject of complaint among the practitioners, but no steps are taken to remedy the grievance.

MEDICAL PRACTITIONERS AND VACCINATION CERTIFICATES.—Some members of the profession in Falkirk appear to have adopted a novel and not very dignified method of enforcing the payment of

debts due to them, *viz.*, by refusing vaccination certificates to patients who have unpaid accounts standing against them. The matter came up at the Parish Council recently by the inclusion of such persons on the list of vaccination defaulters, and the consequent expense involved by orders being sent to the public vaccinator to attend them. The Local Government Board stated to the Council that while it was, in their view, illegal for a medical practitioner who had successfully vaccinated a child to refuse a certificate, there was no means of compelling him to do so. They advise remonstrance, and failing that a threat of prosecution of the defaulter, which would compel the patient to pay his fees and get the certificate. Would it not be far more straightforward and business-like to sue the patients directly than to resort to this indirect method of obtaining payment of just debts?

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

SMALL HOSPITALS, THE FUNDS, AND THE LONDON HOSPITAL.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—You write of the £6,000 invested by the London Hospital in a sports ground that the money "was devoted to the purchase of a sports ground, not as a Hospital endowment investment." What do you mean? The money was sold out from one investment—we had then about £200,000 invested—and put into this sports ground investment as one that would pay a better interest, and certainly increase in value. The investment had the double advantage of being a very excellent "endowment investment," as you call it, and also in providing our students with an excellent cricket ground which is good for the tone and *esprit de corps* of the hospital. The club were anxious to borrow the money of us and buy the land themselves, but acting on expert advice we bought the land and let it to them at a rent which pays the hospital 4 per cent. It is a travesty of words to call this a "diversion of funds," any more than if we had bought railway debentures.

I am, Sir, yours truly,

SYDNEY HOLLAND.

Kneesworth Hall, Royston, Herts., Jan. 2nd, 1905.

[Mr. Holland *confuses* the issues. Can the purchase of a site for medical schools be called a pure Hospital investment? The money was given by subscribers—either direct, or through one of the Funds—for the benefit of the sick poor—not to purchase cricket grounds for medical students.—Ed. M.P. & C.]

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

"Play fair, and do not show any personal animosity in controversial criticism."—SYDNEY HOLLAND.

SIR,—Mr. Sydney Holland's methods of controversy with me are, I believe, unique. As a person interested in hospitals and their management I venture to criticise what I believe to be an unjustifiable diversion of the funds of the London Hospital. Mr. Holland thereupon, among other epistolary elegancies, taunts me with not being a subscriber to the London Hospital. I then send a subscription. It is returned to me with impertinent allusions to my motives. Mr. Holland then makes assertions based on the accounts of the College to which I am refused access.

In such circumstances, I may reasonably be excused from participating in further discussion with him, and in any case, unless he can avoid introducing personalities into a discussion on a matter of public interest, I would rather address myself elsewhere. I think he must have discovered at the Mansion House the other day that to be personal is not necessarily to be convincing.

In conclusion, may I be permitted to say that if a

hospital manager takes upon himself to sit in judgment upon the motives of subscribers, some very large subscriptions might possibly have to be returned!

I am, Sir, yours truly,
STEPHEN COLERIDGE.

Victoria Street, London, S.W. Dec. 29th, 1904.

HOSPITAL FUNDS AND SMALL HOSPITALS.
To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR.—Though Mr. Sewill is apparently one of those who consider that repetition and argument are the same, he has gone a little too far when he speaks of the general hospitals being practically beyond criticism. H.R.H. the Prince of Wales told a very different story, and £39,000 for a beginning is a nice little sum to waste.

While it is possible that some of the special hospitals have been started without any very high motive, I would like to hear from Mr. Sewill if he knows of any physician or surgeon attached to any London hospital, general or special, who does not expect to be helped on in the world through his connection with the hospital.

Some day I hope that the question of taking fees from hospital patients will be thoroughly inquired into.

I hold no brief for any hospital—indeed, when asked to which hospital money should be given, I invariably recommend that the money be given in private charity to avoid waste. Talking on this subject lately with a wealthy man who gives largely to one of the general hospitals, I was surprised to hear him say that he was beginning to think very much the same. He had been making inquiries, and was amazed at the waste he was told of. Reform the special hospitals when needed by all means, but do not let us have any more of these unworthy flouts about advertising; we lately had an example of how to do it, where three general hospitals were represented.

I am, Sir, yours truly,
OUTSIDER.

CONSUMPTIVE HOSPITALS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR.—I am glad to see that you are directing attention to the question of the practical value of consumptive hospitals. The surroundings of the hospital at Brompton are not improving, and a very little now would lead to the neighbourhood being deserted. Very few would care to live in an atmosphere like that.

I am, Sir, yours truly,
R. L.

WORKHOUSE INFIRMARIES—COST PER BED.
To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR.—Can any subscriber give me an instance, or tell me if it is possible to erect a workhouse infirmary with administrative accommodation fitted up with modern sanitary accessories which will meet the requirements demanded by the Local Government Board at a cost of less than £90 per bed?

I am very interested in this description of work, but have never found a case where the cost was less than the sum mentioned. If anybody could enlighten me on this matter I should be very grateful.

I am, Sir, yours truly,
A SUBSCRIBER.

January 2nd, 1905.

Obituary.

DR. LOCKHART GILLESPIE, EDINBURGH.

By the sudden death on Christmas Day of Alexander Lockhart Gillespie, M.D., F.R.C.P.Ed., a career which showed every sign of brilliancy was unexpectedly cut short. He was a member of an old Edinburgh family being the son of a distinguished surgeon and the grandson of an equally well-known physician; to his own undoubted attainments were thus added the prestige which an inherited and traditional association with medicine bestows. He graduated in 1888, and in 1892 had conferred on him the degree of M.D., receiving at the same time a gold medal for his thesis. In 1894

he obtained the Freeland Barbour Fellowship of the Royal College of Physicians for original research, a field for which a critical intellect combined with an original and versatile temperament specially fitted him. The branch of medicine to which he particularly devoted himself was that of disorders of digestion, and a series of articles on this and allied topics culminated a few years ago in the appearance from his pen of a volume on the natural history of digestion published in the Contemporary Scientific series, and of a manual of modern gastric methods in which the diagnosis of diseases of the stomach was exhaustively treated. Dr. Gillespie was a recognised authority on the subject on which he wrote, and his opinion on difficult or doubtful cases was sought after and valued by his professional brethren. He held numerous important public appointments, some inherited from his father, among which his position as Surgeon to the Merchant Company, to the Institution for Incurables, and to Donaldson's Hospital, may be enumerated. For twelve years he was medical registrar to the Royal Infirmary, and in the duties connected therewith, as well as in a series of tables on medical meteorology, published monthly in the *Edinburgh Medical Journal* he found work rendered congenial by his talent for statistics. Apart from his attainments in Medicine he possessed in marked degree the journalistic sense, was an artist of considerable talent, and, like his father, excelled as a song writer. He was for many years on the staff of the *MEDICAL PRESS AND CIRCULAR*, of the *Medical Magazine*, and of the *Edinburgh Medical Journal*, and the facility with which he could write racy and sparkling articles was the envy of many among his acquaintances. He married a daughter of the late Dr. Blair Cunynghame, and is survived by three children, but his last months were saddened by the loss of his wife, who predeceased him a year ago, and he never completely recovered from the shock of this bereavement. He was in his usual health only a few days before his death, and succumbed quite unexpectedly to sudden heart failure on the morning of December 25th.

THOMAS HENDERSON POUNDS, F.R.C.S.ENG.,
L.S.A.

WITH regret we announce the death of Dr. Thomas Henderson Pounds at his residence, Friar Gate, Derby, on the 27th ult., from the effects of injuries sustained some three weeks ago while motoring. A dog ran across the road, and in the sudden attempt to avoid a collision the steering gear of the car became deflected and he was thrown out. Dr. Pounds was the son of Captain Pounds, R.N., of Plymouth, was educated at Charing Cross Hospital, and became F.R.C.S. in 1884. He was a Fellow of the British Gynaecological Society, a member of the North of England Obstetrical Society, and author of several contributions to the medical journals. In Derby he had acquired considerable reputation in surgical cases, and it was through his instrumentality that the Derbyshire Hospital for Women, an institution which does excellent work in Derby, was established. Dr. Pounds, who was only forty-eight, leaves a widow and a young family.

JAMES ARMSTRONG, M.B.ED., OF LIVERPOOL.

WE regret to announce the death, under painful circumstances, of Dr. James Armstrong, recently in practice at Rodney Street, Liverpool. His body was found at a farmhouse near Llandyrnog, where he and his family had for some time been staying. The inquest showed that death was due to the accidental discharge of a gun. Deceased was educated at Edinburgh University, where he took the M.B. degree in 1868. At the time of his death he was Consulting Physician to the Lying-in Hospital, and formerly Physician to the Liverpool Hospital for Children.

EDWARD TREHARNE, L.R.C.P. & S.ED.,
AND F.P.S.GLAS., J.P.

WE regret to announce the death of Mr. Edward Treharne, J.P. for the county of Glamorgan, with painful suddenness at his residence, Cadoxton House,

Cadoxton-Barry, on the 29th ult. He had been out during the night on professional duties. When he got up in the morning, about nine o'clock, he appeared to be in his usual good, robust health. Soon afterwards, however, he fell back on the bed and died. The deceased, who was one of the most highly-respected practitioners in the Barry district, was only forty-two years of age. He leaves a widow and two children. Dr. Treharne was the son of Mr. David Treharne, Pentre-Rhondda. He was a member of the old Barry and Cadoxton Local Board of Health, and subsequently of the Barry District Council, and had been chairman of the latter body. He also held a seat on the Glamorganshire County Council. He was public medical officer for the Cadoxton district of the Cardiff Union. He was made a J.P. for the county about five years ago.

DR. ADAM, OF LIVERPOOL.

WE deeply regret to have to announce the death of Dr. Adam, late of Shaw Street, Liverpool. The melancholy event took place on the 19th ult., at 38 Princes Avenue, where he was temporarily staying. He was educated in Dublin and took the M.R.C.P.I. in 1880, and M.D.St.And. 1880, and M.R.C.S.Eng. 1857. Up to a few years ago Dr. Adam was one of the most active members of the profession in the city of Liverpool. He was an able and well-read man, and his natural aptitude for the details of his profession, both as regards diseases and patients, amounted to what may be called genius. Although a man of firm opinions he never made an enemy, and by all who had the privilege of knowing him he was admired, esteemed and loved. He was an Irishman and one who possessed the characteristics peculiar to the inhabitants of the Sister Isle—brightness, cheerfulness, kindness, and *bonhomie*; a fine speaker, he was always listened to with even more than interest. Take him all in all, he was a typical medical practitioner of the better sort. For some years his health had been failing, a laryngeal affection, that caused breathlessness on exertion and especially when associated with a bronchial catarrh, was very hard to bear, and he himself was fully aware that his days were nearly numbered. His friends hoped for something better, but it was not to be. A deeper or more heartfelt sorrow has rarely been aroused than has been by the death of this gentleman. The writer feels that only one word can adequately describe all that Dr. Adam was to patients as well as to friends—he was essentially and intensely—human.

FRANCIS HENRY BLAXALL, M.D.ST.AND., M.R.C.S.ENG., L.S.A., R.N.

DR. FRANCIS HENRY BLAXALL, Retired Fleet Surgeon, Royal Navy, died last week at Clan Lodge, Bath, in his seventy-ninth year. He entered the Naval Medical Service in 1848, and during the Russian War was Assistant Surgeon of the *Colossus* in the Baltic, receiving the medal. He was promoted to be Staff Surgeon in 1856, took the M.D. Degree at St. Andrews in 1861, and became a Fleet Surgeon in 1869. After his retirement from the Navy he acted as Medical Inspector of the Local Government Board at Liverpool.

DR. J. R. WOLFE, GLASGOW.

WE regret to announce the death, on December 26th, of Dr. Wolfe, at the advanced age of eighty years. He took the M.D. Degree, Glasgow University, in 1856, and was elected F.R.C.S.Edin. in 1868. He was an excellent linguist, and before commencing practice in his own country, he went through the campaign in Italy with Garibaldi as surgeon on the personal staff. On returning to Scotland he was appointed Ophthalmic Surgeon to the Aberdeen Royal Infirmary, and making ophthalmology his principal study, he subsequently went to Glasgow, where he attained considerable eminence as the leading oculist in that city. Nor was his reputation confined thereto, as by his modification of the operation, as then practised; for the extraction of cataract in cases of detachment of the retina, he succeeded by aspiration in restoring the retina to its normal

position, and his name became known and his operation adopted throughout the ophthalmic world. He was the founder of the Glasgow Ophthalmic Institution, where for many years he did excellent work, and from time to time he held post-graduate courses there, which were largely attended by medical men. He was also for some time Professor of Ophthalmology in St. Mungo's College. Dr. Wolfe was a frequent contributor to the columns of this journal and was the author of one or two excellent treatises on diseases and injuries of the eye. Some few years since his health gave signs of breaking down, and this induced him to relinquish practice in Glasgow and to seek the sunnier clime of Australia, where his reputation had preceded him, and he was appointed Surgeon-Oculist to the Governor of Victoria. He returned to this country about four years ago, and had been living in retirement until his death. He leaves a widow and children to mourn their loss, two sons being members of the medical profession.

HERBERT WILLIAM KNOWLES, M.R.C.S.ENG., OF ST. HELEN'S.

WITH regret we announce the death, on December 28th, of Dr. Herbert William Knowles, a well-known St. Helens doctor, who carried on an extensive practice with his brother, Dr. Fred Knowles. The deceased was only taken ill on Friday last, when he had a heart attack, and was confined to bed. He was apparently progressing well, but subsequently had a second attack, which resulted fatally. Dr. H. W. Knowles, who was forty-eight years of age, was a native of St. Helens, and leaves a widow and a son and daughter. He was medically educated at Liverpool, and at University College, London, whence he took the M.R.C.S.Eng. in 1882.

CHARLES SMITH, M.R.C.S., BANFFSHIRE.

MR. CHARLES SMITH, of Marnoch, Banffshire, died on December 29th at the age of eighty-five. He was educated at the old Marischall College, Aberdeen, and took the M.A. degree in 1838. Four years later he qualified as M.R.C.S., and in 1892 he celebrated his professional jubilee. Mr. Smith, who had retired from practice, was one of the best-known doctors in the north-east of Scotland.

JOHN THOS. JONES, L.R.C.S. & P.ED. OF HOLY- WELL, FLINTSHIRE.

WE regret to record another death from accident in the person of Dr. John Thomas Jones, who died on Christmas Day. At the inquest held over him, evidence was given to the effect that in August last Dr. Jones was struck in the groin whilst getting into a waggonette through the door flying back. Internal complications set in, and he succumbed on Christmas Day, at the age of forty-five. Dr. Jones leaves a widow and four children. He qualified in 1884, and began practising as a surgeon and physician at Gronant twenty years ago, removing first to Llanasa and then to Lfynnongroew.

Literature.

DISEASES OF THE STOMACH. (a)

THE deservedly great name of the authors will ensure a good reception for this work, but, apart from this consideration, its intrinsic value makes it incumbent on all abdominal surgeons carefully to study its contents. Those who have followed the advance of gastric surgery, as recorded in the various journals, will doubtless find little in this book which could be called new, as Messrs. Mayo Robson and Moynihan have never been diffident about publishing their work and statistics; but it is nevertheless convenient to review their cases and conclusions in book form. The descriptions of operations are very concise and clear, and the indi-

(a) "Diseases of the Stomach and their Surgical Treatment." By Mayo Robson and Moynihan. Second Edition, pp. xiv and 508; illustrations, 108. Demy 8vo, price 15s. net. London: Bailliere, Tindall and Cox, 1904.

cations for operation well defined; but, knowing what a large number of gastric cases have been under observation by the authors, we might suggest more clinical details and more definite descriptions of mechanical and chemical aids to diagnosis in the next edition. The chapter on perforation might be greatly improved, as the description given will hardly lead to the recognition of many cases in time for successful operation, and the directions for treatment lack definiteness. It would be hard to conceive anything better than the description of gastro-enterostomy, and we heartily congratulate the authors on their brilliant results.

ENLARGEMENT OF THE PROSTATE. (a)

THIS is a volume which we can confidently recommend to the senior student and young practitioner. The anatomical and pathological descriptions are concise and quite sufficient. The clinical course of the disease is treated in a manner which shows an intimate knowledge of such cases on the part of the author, whilst the chapters on the treatment, although short, and on the whole, perhaps, not quite up-to-date, are written in such a dispassionate and broad-minded tone that they must prove useful.

Most works on this subject of late years have begun with a fight over "capsule" and "sheath," and have ended in special pleading for some one operation.

The present book is quite free from these blemishes, and although it contains nothing new, yet it is refreshing.

Medical News.

The Otolological Society of the United Kingdom.

The following members were elected as officers and members of Council for the ensuing session 1904-05:—*President*, Thomas Barr; *Vice-Presidents*, Alphonso Elkin Cumberbatch, John B. Story, Cresswell Baber; *Honorary Treasurer*, Edward Law; *Honorary Librarian*, Herbert Tilley; *Hon. Editor of "Transactions"*, Jobson Horne; *Council*, Urban Pritchard, Arthur Whitehead, Logan Turner, Arthur Cheatle, Richard Lake, Ernest Waggett; *Honorary Secretaries*, Hugh E. Jones, Macleod Yearsley.

Vital Statistics.

THE deaths registered last week in eighty great towns of the United Kingdom corresponded to an annual rate of 19.4 per 1,000 of their aggregate population, which is estimated at 17,139,295 persons in the middle of last year. In the preceding three weeks the rates had been 21.6, 18.5, and 19.2. The highest annual death-rates per 1,000 living, as measured by last week's mortality, were:—from *all causes*, 17.0 in Edinburgh, 17.6 in London, 20.6 in Belfast, 23.7 in Glasgow, 24.5 in Dublin, 25.0 in Bury, 25.3 in South Shields, 25.5 in Newcastle-on-Tyne, 25.6 in Rhondda, 26.5 in Manchester, 27.0 in Stockton-on-Tees, 28.5 in Tynemouth, 29.1 in Middlesbrough, 31.9 in Huddersfield, and 32.6 in Hanley; from *measles*, 1.3 in Nottingham and in Rhondda, 1.4 in Liverpool and in Merthyr Tydfil, 1.8 in St. Helens, 2.0 in Stockton-on-Tees, 2.2 in Stockport, 3.1 in Grimsby, 3.3 in Wigan, and 4.8 in Devonport; from *scarlet fever*, 1.3 in York, and 1.6 in Hanley; from *diphtheria*, 1.6 in Hanley, 1.7 in Wigan, and 1.8 in East Ham; from *whooping-cough*, 1.3 in Rhondda, 1.4 in Norwich, 2.0 in Tynemouth, 2.7 in Preston, and 2.9 in Halifax. One death from *small-pox* was registered in Gateshead, but none in any other of the large towns.

Plague at Bangkok.

The suspected outbreak of plague at Bangkok has been definitely confirmed. Two more deaths have occurred. It is hoped, however, that it will be possible to prevent the disease from spreading.

Alleged Poisoning on a Honeymoon.

DR. IVAN BRAUNSTEIN, a well-known physician, of

Munich, has been arrested on a charge of poisoning his wife under peculiar circumstances. After his marriage early in the year with a wealthy young lady from Halle, the newly-wedded pair started for Italy on their honeymoon. Frau Braunstein died on this journey, and it is now alleged that her husband mixed poison in her food at various hotels in such a way that her death was gradual. His object, it is stated, was to obtain sole possession of his wife's wealth. The case has created intense interest throughout South Germany.

Allingham Scholarship.

MR. HERBERT WILLIAM ALLINGHAM, F.R.C.S. Eng., by his will bequeathed £2,000 or the residue of his estate, if less than that sum, to St. George's Hospital, to found a surgical scholarship to be named the "Herbert Allingham Surgical Scholarship," the sum to be invested separately, in permanent funds, and 10 guineas out of the income are to be paid to the examiner for the scholarship annually and the residue of the income in such way as the governors of the hospital may direct.

The Status of Hospital Ships.

THE International Convention concerning the status of hospital ships in war time was signed at The Hague by the following States:—France, Germany, Russia, Austria-Hungary, the United States, Holland, Belgium, Denmark, Spain, Greece, Luxemburg, Portugal, Roumania, Servia, Japan, China, Korea, Siam, Mexico, and Persia.

The Gresham Lectures.

DR. E. SYMES THOMPSON will deliver a course of lectures on "Evolution in the Vegetable Kingdom," at Gresham College, Basinghall Street, E.C., on Jan uary 17th, 18th, 19th, and 20th, at 6 o'clock. The lectures will be illustrated by diagrams, and are free to the public.

PASS LISTS.

University of London.

THE following passed the M.D. Examination for Internal and External Students (Branch I Medicine), during December, 1904:—Wm. Maurice Anderson, B.S., Alfred Armer, Joseph Hugh Arthur, Joseph Barnes Burt, Janet Mary Campbell, B.S., Archd. Robt. John Douglas, B.S., Ronald Hatfield, Herbert Charlton Jonas, B.S., Frederick Samuel Langmead, Joseph John Scammell Lucas, B.A., Greer Edmund Malcomson, William John Morrish, Eugene Michael Niall, B.S., Ralph Norman, Harold Edward Ridewood, Charles Newton Sears, B.S. (obtained the number of marks qualifying for the University Medal), Arthur Rendle Short, B.S., B.Sc. (University Medal), Ernest Wethered, Owen Thomas Williams, B.Sc., Louisa Woodcock, B.S., Guy Theodore Wrench, B.S.

The following passed the M.S. Examination for Internal and External Students:—Frank Barnes, Reginald Cheyne Elmslie (obtained the number of marks qualifying for the University Medal), Lawrence Jones, Cyril Alfred Rankin Nitch (University Medal), Florence Elizabeth Willey, B.Sc., Ernest Eric Young.

Society of Apothecaries of London.

DURING the December Examinations the following candidates passed in:—

Surgery.—W. Archer, J. J. Comerell (sections I. and II.), P. C. Franze, F. E. Gubb (section I.), M. E. Jeremy (sections I. and II.).

Medicine.—J. J. Comerell (sections I. and II.), W. L. Crabtree, P. C. Franze, J. A. R. Wells (sections I. and II.), P. B. Whittington (sections I. and II.).

Forensic Medicine.—P. C. Franze, F. E. Gubb, W. V. Pegler, A. F. Reardon, P. L. Vawdrey, R. J. S. Verity, P. C. West, P. B. Whittington.

Midwifery.—D. L. E. Bolton, J. J. Comerell, P. C. Franze, F. E. Gubb, C. F. Kernot, J. W. Rollings.

The L.S.A. Diploma of the Society was granted to the following candidates, entitling them to practise Medicine, Surgery, and Midwifery:—W. Archer, P. C. Franze, and P. B. Whittington.

(a) "Enlargement of the Prostate: its Treatment and Radical Cure." By O. Mansell Moullin, M.D. Oxon., F.R.C.S., Third Edition. 8vo. Pp. xii+304. Price 6s. London: H. K. Lewis, 1904.

Notices to Correspondents, Short Letters, &c.

Correspondents requiring a reply in this column are particularly requested to make use of a distinctive signature or initial, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

ORIGINAL ARTICLES or LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

CONTRIBUTORS are kindly requested to send their communications if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in re-forwarding from office to office. When sending subscriptions the same rule applies as to office, these should be addressed to the Publisher.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

MEDICAL CERTIFICATES.

At Merthyr on Thursday Mr. Frank T. Jones appeared on behalf of the managers of the Gelligaer elementary schools, to prosecute several parents for not sending their children regularly to school, and he complained that medical practitioners in the parish gave medical certificates with too much ease, with the result that the attendance throughout the district had fallen off considerably. Sir T. Marchant Williams, the learned Stipendiary, said the bench attached very little importance to medical certificates. They could not act upon these certificates; but if the doctors came to court themselves and gave evidence, then they could give due weight to their testimony.—*Western Mail*.

H. K. WRENCH (Bangor).—(1) Little is now heard of scoury, although there were some cases, we believe, in the South African War, and some have been reported from the Far East in the present Russo-Japanese War. Want of fresh food generally is a more correct way of describing the cause than merely want of fresh vegetables. It has been shown that the malady may be induced in the absence of fresh animal food, even when there are plenty of fresh vegetables available. (2) A copy of the issue you mention can be had by applying to the office of this journal.

A DOCTOR'S JOKE.

Dr. Little Glenfalls, of New York, is said to have sent a thousand patient's a handsome silver spoon inscribed, "Dedicated to the patients who have survived my practice." The presents cost over 2,000 dollars.—*Lafayette*.

R. F. W. (Leicester).—Stones in the kidneys occasionally reach very great size: an ever-present danger is rupture. In one case death followed rupture of the kidney in a football player who suffered from a large unsuspected renal calculus.

W. A. SMITH.—Consult one of the medical dictionaries: you will find all the information you seek in Gould's larger dictionary, an excellent work.

A. E. MALDON.—If you take our advice you will write at once, whether you are a member of the Society or not, to A. J. Bateman Esq., M.B., Secretary Medical Defence Union, 4 Trafalgar Square, London, W.C.

THE OLD MEDICAL BOTANISTS.

BECAUSE of the familiar little blue Lobelia we can never forget Matthias de L'Obel, that ever doctor who travelled about Europe studying plant life, and who practised medicine in Holland before he came to England to be physician and botanist to James I. It is noteworthy that the botanists of those days were almost invariably physicians too, for mineral remedies were practically unknown, and hence it was to doctors, in their search for new remedies in their profession, to whom plant study naturally fell. Therefore there was nothing strange or derogatory in the fact that Matthias de L'Obel had charge of Lord Zouche's garden at Hackney, in addition to, or perhaps even as an aid to, his medical work. An old engraving in the Tyase Library at Hackney, presents him as a venerable old man with a noble forehead and bushy beard, holding a flower in his hand. He was so far in front of his contemporaries that it is in his writing that we first find the rudiments of a scientific classification of plants.—From "The Leisure Hour," for January, 1905.

R.R.R.—The law is clear on the subject whether applied to the individual or combination of persons, prohibiting any one to take charge of the insane or idiots unless specially licensed under the Act.

Meetings of the Societies, Lectures, &c.

THURSDAY, JANUARY 5th.

ROYAL SOCIETY (29 Hanover Square, W.).—8.15 p.m. Mr. C. E. S. Phillips: (1) Description of an Automatic Vacuum Pump (the

apparatus will be shown at work); (2) Exhibition of a Method by which Strongly Adherent Films of Aluminium may be applied to Glass; (3) A Note on the Colouration of Glass by Radium Radiation.

NORTH-EAST LONDON CLINICAL SOCIETY (Tottenham Hospital, N.).—4 p.m. Discussion on the Medical-Legal Aspects of Alcoholism (opened by Dr. A. J. Whiting).

Bacancies.

Clayton Hospital and Wakefield General Dispensary.—Senior House Surgeon. Salary £180 per annum with board, lodging, and washing. Applications to the Hon. Secretary, Clayton Hospital, Wakefield.

Clayton Hospital and Wakefield General Dispensary.—Junior House Surgeon. Salary £90 per annum, with board, lodging, and washing. Applications to the Hon. Secretary, Clayton Hospital, Wakefield.

Borough of Scarborough.—Medical Officer of Health. Salary £250 per annum. Applications to D. Arthur Nicholl, Town Clerk Town Hall, Scarborough.

Hospital for the Insane.—Assistant Medical Officer. Salary £100 per annum. Applications to the Medical Superintendent, the Lawn Hospital, Lincoln.

Royal Dental Hospital of London.—Mechanical Pupils' Department. Demonstrator. Salary £120 per annum. Applications to the Dean, 32 Leicester Square, W.C.

Lancashire County Asylum, Winwick, Warrington.—Assistant Medical Officer. Salary £180 per annum, with furnished apartments, board, attendance, and washing. Applications to the Medical Superintendent.

Lancaster County Lunatic Asylum.—Assistant Medical Officer. Salary £150 per annum with board, lodging, washing, &c. Applications to the Medical Superintendent.

Royal City of Dublin Hospital.—Resident Medical Officer. Applications to Mr. G. Jameson Johnston, F.R.C.S. (See Advt.)

Appointments.

GOLDBIE, F. M. M.D. Edin., Public Vaccinator to the Woodford District of the West Ham Union.

GROVES, E. W. HET, M.D., B.S., B.Sc. Lond., L.R.C.P., M.R.C.S., Demonstrator of Anatomy at University College, Bristol.

JONES, E. T., M.R.C.S., L.R.C.P. Lond., Certifying Surgeon under the Factory Act for the Helston District of the County of Cornwall.

LAPAGE, C. P., M.B., Ch.B. Vict., Senior Resident Medical Officer to the St. Mary's Hospital, Manchester.

PARK, A. GLEN, M.D. Glasg., Certifying Surgeon under the Factory Act for the South Bolton District of the county of Lancaster.

PICTON, GUY BROUGHAM, M.B., B.S. Durh., District Medical Officer to the Redruth (Cornwall) Board of Guardians.

PRICE, FLORENCE M. S., M.B., Ch.B. Edin., House Physician to the Swansea General and Eye Hospital.

SCHOSTEIN, GUSTAV, M.D., M.A. Oxon., F.R.C.P., Physician to the Brompton Hospital.

STOCK, W. S. VERNON, M.D., B.S. Lond., L.R.C.P., M.R.C.S., Demonstrator of Anatomy at University College, Bristol.

Marriages.

HAMOND—TILLEY.—On December 29th, at St. Peter's Church, West Hants Hill, near Bridgwater, Philip William Hamond, M.B. Lond., M.R.C.S., &c., son of J. Blomfield Hamond, of Upper Norwood, to Francis, second daughter of Mrs. Tilley and the late Edward Tilley of Hants Hill.

HARLEY—BLAGDEN.—On December 29th, at Stone Church, near Aylesbury, Edward Vaughan Berkeley, son of the late George Harley, M.D., F.R.S., to Mary eldest daughter of the Rev. Canon Blagden, Peverel Court, Aylesbury.

LE BAS—DE CRESPIGNY.—On December 29th, at St. Peter's, Eaton Square, London, Dumaresq Le Bas, R.A.M.C., only son of the late Dumaresq Le Bas, of Monte Video, Uruguay, to Mary de Crespigny, widow of Robert de Crespigny, of Sandy Mount, Dublin.

MAURICE—GIFFARD.—On December 27th, at the Church of St. Michael and All Angels Overton, Wilts, Thomas Hector Molesworth, Lieut. R.N., H.M.S. "Bulwark," son of J. Blake Maurice, M.D., J.P. of Lloras House, Marlborough, to Cicely, second daughter of H. Eyecroft Giffard, Esq., J.P., of Lockeridge House, Marlborough.

WRIGHT—TERRELL.—On December 29th, at St. Mary Abbott's, Kensington, George Angus, M.B. B.C. Cantab., youngest son of Hugh Wright, Esq., J.P., of Alniory, Wigtownshire, to Nellie Noel, eldest daughter of Gilbert Howard a Beckett Terrell, Esq., of Great Fishall Hall, Tonbridge.

Deaths.

HOLDSWORTH.—On December 28th, at 5 Sinclair Gardens, Kensington, W., John Hall Holdsworth, Esq., M.D., aged 94, son of the late Joseph Holdsworth, Esq., J.P., Coplow House, Leicestershire, and Lord of the Manor of Ellenden.

KNOWLES.—On December 28th, at Harshaw Street, St. Helens, Herbert William Knowles, M.D., aged 48 years.

WATTS.—At 5 Upper Addison Gardens, Kensington, Anne Watts, widow of the late John Watts, M.D., of Shrewsbury aged 86.

Vienna Clinical Lectures.

THE CLINICAL VALUE OF RADIOGRAPHY IN TRAUMATIC INTRA-MUSCULAR OSTEOMAS.

By DR. R. KIENBÖCK,

Principal of the Radiographic Institution, Vienna.

[SPECIALLY REPORTED BY OUR VIENNA CORRESPONDENT]
PART II.

CASE IV is that of a saddler, æt. 19, who when examined by the rays had six weeks previously fallen on his right elbow, which had become greatly swollen and painful. Mechano-therapy had been applied with no success. At the time of examination extension was very limited, but no œdema. In the sulcus of the bicipitalis internus a hard, irregular and movable tumour about the size of a child's fist could be felt. The Röntgen rays revealed a long pediculated shadow as seen in Fig. 3 in front of the humerus, 6 centimetres long. The fine attachment was 1 centimetre broad and 2 centimetres long, oval in shape, and irregular on the surface. Its constituents appeared in bands and layers, with a large white area on the inner side of the growth. At the level of the fossa olecrani fine bands could be seen passing backwards to the humerus. When the shadow was taken from behind, the neoplasm could be seen rising 4½ centimetres above the epicondylus. Fine fibres could be seen entering the epiphysis of the humerus laterally. When viewed laterally, another shadow of small dimensions was observed to be connected with the distal posterior part of the humerus. No injury could be observed about the extremities of the bones around the joint. Six weeks later the conditions were much the same. Moseitig finally operated to relieve movement, and removed all the bony structure from the brachialis internus with its insertions into the ulna.

Case V was a boy, æt. 14, who received a contused wound on the right elbow, which under the rays showed the arm in a half-flexed condition, with pain on movement. Above the joint was impacted a bony hard tumour among atrophied muscles, irregular on the surface and immovable, commencing at the epiphysal line, and extending 8 centimetres upwards parallel with the humerus. At some places it was near the humerus, at others more adjacent to the skin. On the posterior side of the humerus a small, thin shadow could also be observed. No abnormal changes could be found in the bones about the joints.

Case VI was a young man, æt. 19, who fell on a hillside and dislocated his elbow, which was speedily reduced, leaving a good deal of swelling. A few weeks after a distinct hardening took place, with a hard swelling about the size of a walnut, irregular surface, and lying in the sulcus of the bicipitalis internus. The medical radiogram revealed a well-defined shadow between the elbow-joint and plica cubiti,

arising from the front of the diaphysis of the humerus, with thin, spiny connections. The whole appearance was arrow-like, 4 centimetres long, with an isolated portion in the brachialis internus. It appeared to be composed of bone, cartilage, and fibrous tissue. A clear, fine fibre could be seen extending into the distal end of the humerus. Posteriorly there was also a dark shadow to be observed. Humerus, ulna and radius were perfectly healthy.

Case VII.—A female, æt. 28, was thrown from an automobile and dislocated the elbow, followed by pain and swelling. After reduction, the arm was carried in a sling for several weeks till it became stiff. Eight weeks after the accident the Röntgen rays were applied, when the arm could not be extended beyond 70°. Movement passively was difficult, pronation and supination impossible. Fracture or injury to the head of the radius was suspected, although there was no deformity beyond a hard swelling in the brachio-radialis muscle. The radiogram proved the bones to be entire. Behind the humerus was a dark shadow, which was uneven, as well as one in front having connection with the capsule. Higher up was another shadow about the size of a bean, oval, and lying in front of the diaphysis.

Case VIII was a man, æt. 30, who received an injury to the right elbow from the butt end of a gun in recoil while hunting. Swelling, pain, &c., took place much in the same way as in the preceding. The radiogram revealed a dark shadow in front of the humerus under the green coloration of the skin on the right arm where the gun had recoiled. The biceps had a bony hardness with no pain. This hardness was not evenly distributed, but arranged in bands along the muscle, passing well behind the humerus into the fold of the axilla; this all appeared confluent in the radiogram. Three points should be noted in this case:—(a) In the region of the axilla one of these hard masses about the size of a hazel nut had a fine shadow connection with the bone, measuring 35 millimetres from the humerus; (b) a section 2 centimetres thick stood out as a separate dark band; (c) at the distal end of the humerus two other sections appeared, both tapering into one centre at the lower end of the bone, with a fine pedicle 11 centimetres long.

In these eight cases I have just cited we have a complete picture of the course taken by a typical intra-muscular osteoma arising from a simple accident, of which there are another twenty recorded in literature on the subject, of which twelve are in the quadriceps cruris, six in the brachialis internus, one at the insertion of the deltoid, and one in the latissimus dorsi, most of these having been operated on and confirmed by the microscope.

In my own cases, the reader will observe six of them were located at the elbow with ossification of the musculus brachialis internus, Cases 3 and 4 being confirmed by operation. In both these cases the osteoma was movable. In No. 3 no connection was observed with the skeleton, while No. 4 had a pedicle connecting it with the ulna. In the other four cases the osteoma was connected with the humerus.

It will be seen from my own cases that they are not in accord with the others, which had the greatest number connected with the quadriceps cruris, while my own have the greatest number in the brachialis internus. This is not a matter of much consequence as the numbers are not great enough to determine the frequency of site. What is common to all is the injury either in the form of distortion, stretching or luxation, having in all cases a common clinical symptom. The manner of ossification in the supinator muscles or the biceps brachii, as recorded in my seventh and eighth cases, is not common to the disease, but the nature of the accident in No. 8, which was from the recoil of a rifle, is a peculiar cause of the lesion, which may also be noted here, as dislocation at the elbow-joint is the most common cause. It is worthy of note that this case was associated with osteo-arthritis, as the radiogram showed changes on the surface of the articulations and ossification of the capsule, with slight atrophy of the spongy portion at the end of the long bone, which accounted for the ankylosis of the elbow-joint.

The next character to be noted is the time taken before the growth becomes fully developed after the accident. In my own cases the first had reached its full size after six weeks; in the second case it was seven months after the accident before it reached its full size; in the third case it was eight weeks; in the fourth it was six weeks; in the fifth it was four weeks; in the sixth it was five weeks; in the seventh case it was seven weeks; and in the eighth case it was only three weeks. It seems, therefore, that after a definite time the osteoma remains stationary, which may guide the operator in determining whether an operation is necessary or not. This corresponds with Schuler's results, which gave the limits of the growth from a fourth of a year to two and a half years after the accident, which occurred mostly in his cases in the femur. Another point to be remembered is that after extirpation there is no return, and that those that have been operated on radically show an anatomical connection with the periosteum, and that near the end of the long bones.

In closely examining the radiogram we find the dark shadow confined to particular sites, having an elongated appearance, parallel with the long bones, and usually a pedicle near the diaphysis. The centre of origin does not seem to be circular, but springs from one part, particularly the anterior side of the forearm, although sometimes it may be slightly lateral in the femur; as a rule confined to the elbow in the upper extremities, and the femur at its lower third or just above the patella in the leg. Sometimes the pedicle is so small that it may pass unobserved in the radiogram. In the upper arm, Case 4 is a good example of the pedicle being obscured where the osteoma appears in front of the humerus; although the pedicle can be traced to the head of the ulna, yet the ossification occurs in the brachialis internus, which may anatomically be explained by the insertion of the tendon. When the tumour is large and round, lying in front of the humerus without any connection, such as in Case 3, but movable, the presumption, though no pedicle can be observed by the rays, is in favour of an osteoma. At the beginning of the formation of the tumour, little or nothing can be seen by the rays till the fourth week has been reached, when a fine outline can be detected in the shadow lying above the diaphysis and having the appearance of bony attachment. About this time ossification usually sets in, although the shadow has a clear centre with a distinct outline. About the fifth or sixth week the hardness can be observed on palpation, the shadow having still the same outline, with a clear centre, as in the third or fourth week, though its circumference has not increased. This is well shown in Cases 5 and 8, three or four weeks after the accident, which agrees with Rammstedt and Grünbaum's observations in the leg. It is common knowledge that new formations of bone tissue before the deposit of lime takes place, such as in the callus of fractures, are transparent and not easily detected

by the rays. Berndt tells us that nothing abnormal could be observed with the rays, although an operation had to be undertaken to remove an osteoma which occurred in a youth, and which was very porous when removed. The density and saturation of the osteoma, therefore, must be considered in diagnosing these growths by the rays, though technical skill is absolutely essential in their detection, as the intensity of the shadow is a diagnostic feature. However, in a large femur three weeks after the accident with a bad diaphragm, the osteoma should be observed. In examining the neoplasm more closely the growth is found not to be homogeneous, but contains several clear areas, sometimes pressed into one region of the growth. The surface of the growth has its elevations and depressions like a land perspective, which often leads to confusion in the diagnosis by isolating it from the diaphysis. A few weeks later the shadow becomes darker and more saturated like the diaphysal end, with internal streaks and spots which, lying parallel to one another, form laminae.

Koehler records a case where this rapid progress did not occur, but took five years to reach this stage. Schuler tells us of one of his that took three years, but as a rule six to eight weeks are sufficient. In old typical cases the shadow gives a connection with the diaphysis of the long bone, although a space is sometimes observed, and no pedicular connection can be seen with the rays. This may be easily confounded with an effusion from the periosteum into the muscular tissue, where ossification and organisation of blood clot may take place, but with careful observation the clear centre in both may be differentiated by the surroundings and palpation. The porous framework of the osteoma and the striped ossification, which prefer the sheaths of the muscular fibre, are unmistakable signs. The real worth of this knowledge by means of the radiograph is interesting as well as useful to the practitioner. In clinical practice he will often meet with hard tumours in this position whose history is uncertain, but it should always be borne in mind that these osteomas have a history of some accident a few weeks prior. They are usually hard and resistant, having neither pain nor oedema, which may lead the clinician to conclude that a fracture had existed, and that callus, and probably a spike of bone, have become organised. In the brachialis a fracture of the head of the ulna or the capitulum of the radius may be mistaken for the neoplasm.

Osteo-myelitis or sarcoma of the diaphysis is another error that might occur. Syphilitic bands in the muscles and myositis ossificans progressiva are other blunders that may be made. In the case of syphilis other parts of the body would be affected, while myositis has a multiple arrangement, and may be found in the muscles of the neck, back, and other parts of the body. In the case of intra-tendinous ossification, confusion of the diagnosis may be at first experienced, but this will be found in other parts of the body, such as the calcaneum and other prominent parts, as an exostosis of the bone sending ramifications into the tendon of the Achilles and the plantar aponeurosis. These ossifications are generally bilateral, arising from slight injuries, and are usually accompanied by slight pain.

According to the diagrams given by Virchow, many of these require careful diagnosis, especially when occurring above the patella and elbow-joint. Arthritis and bursæ occurring after dislocations are other sources of error; while ossification of the tendons of the triceps or quadriceps may be equally misleading. In cases of fracture about the joints with a thick deposit of callus, rupture of the tendons and subsequent ossification, or a fracture of the angle of the olecranon, are all fertile sources of error.

Rosaneo reports a case bearing on this subject worth repeating. A child in its fifth year, of a rachitic nature, suffered from an osteo-clasia in the left tibia about its lower third, which formed a pseudarthrosis on healing. The fibula thickened from functional activity, but subsequently commenced to bend below

the fracture in the tibia, causing a rotation of about 90° outwards. The Röntgen rays revealed a band with an overlapping resembling a new growth in the neighbourhood of the fracture, which apparently lay over the lower and upper third of the bone. From this bony deposit lying over the fracture, extensive lineal projections radiated both up and downwards, giving all the appearance of an intra-muscular deposit. This is not an uncommon phenomenon, as the fibrous tissue at this point has a tendency to calcify with the tibialis anticus. On this account statistics of intra-muscular fibrous tissue and fascia bulk largely in all fractures and injuries about this region, which has been by some termed functional ossification from the callus thrown out at the fracture. This change may be compared with the arthropathy in tabes and syringo-myelitis, osteo-malacia puerperalis and hypertrophic tuberosities. Henrad records one of the latter cases, where a blacksmith got a kick from a horse on the right shoulder. On examination with the rays an enormous exostosis was seen on the right clavicle, which had developed after pain, swelling and functional impairment of the shoulder-joint. Hence the term traumatic exostosis, which is another name for intra-tendinous ossification, and, by closer reasoning, may be the same as intra-muscular osteomas, the site of the bony deposit being the only difference in the pathology. It seems, however, that different muscles by their insertions into the bone are more prone to this change than others, as we find the brachialis internus more frequently ossified than any of the others.

Whether we can connect apophyical, periosteal, and tendinous exostoses with cartilaginous ossification requires finer argument, but the anatomy must be the guide in radiography. It should be borne in mind, however, that all this argument brings us back to the difficulty we commenced with, that it was in the spongiosis of the diaphysis where the intra-muscular excretion commenced, extending along the long bones between the muscles and their fibres, and might properly be termed epiphysial cartilage. The intra-muscular osteoma might be diagnosed from the more compact cortical diaphysis by being more porous in consistence than the bony structure covering the extremities of bones, although their origins are not far apart. In this light Constin may be correct in his conclusion after all, that genuine typical traumatic intra-muscular osteoma was only "exostose ostéogénique," i.e., cartilagineaire.

In conclusion we may accept Wolff's law of the pathogenesis of bone, that it is a functional adaptability in the structure of a tissue that proceeds to form bone, and that fibrous tissue, when injured by the skeleton, such as luxation, fracture, or contusion, will excite it to calcify. He qualifies this with normal and abnormal tissue, the former being accepted in this case, but where the trophic centres are at fault such as in tabes, syringo-myelitic arthropathy, myositis ossificans, &c., the conditions are altered. In the child genuine myositis ossificans does not commence with calcification of the tissue in the primary stage, but with an enfeebling, or weakening, of the fibrous tissue, with subsequent ossification of the structure. It should be remembered that muscular tissue does not produce calcification, neither are its fibres calcified by atrophy, but the calcification and growth of the fibrous tissue may cause the muscular tissue to atrophy and disappear, but in no case is the converse true. This theory of traumatic functional injury may explain ossification in the intra-muscular fibrous tissue, but it still leaves us without adequate reason for the enormous growth and character of the neoplasm that follows. It is possible, as suggested, that fibrous tissue, or a certain class of these, may have functional centres that, when excited, form osseous structures in certain regions, but as yet we have no definite proof to support such an hypothesis, however plausible.

PLAGUE has broken out at Port Florence. Six cases and four deaths are reported

Original Communications.

STRYCHNOS TOXIFERA (BENTH.)
AND OTHER PARALYSERS
OF THE
MOTOR NERVE-ENDINGS. (a)

By GORDON SHARP, M.D.Ed.

At the outset I may remark that all my experiments were conducted on male summer frogs (*Rana temporaria*), and in all the experiments conducted in Great Britain the frogs were pithed, and in all the experiments dealing with action on the motor nerve-endings the main leg artery of one side was tied in the usual manner. In a few of the injection experiments the animals were not pithed, and these were conducted outside Great Britain. Every experiment was controlled. Neither female frogs nor winter frogs were employed, because of the unsatisfactory results which they often yield. Unnecessary details are as far as possible left out, and this communication is only to be looked upon as a statement of the general results obtained.

In 1595-96 Sir Walter Raleigh sailed up the Orinoco River in search of the fabled El Dorado, but had to return without gold. He, however, brought with him that which, perhaps, gave greater pleasure to his scientific mind—namely, a supply of the arrow poison of the Makushi Indians, the wonderful curare. This was its first introduction to Europeans. Its composition was a secret and it remained so till about the year 1799, when Humboldt and Bonpland asserted that, despite the various substances entering into the composition of curare, its active agent was really an extract of *Strychnos toxifera* (Benth.), or other species of the South American vine Urali, and belonging to the natural order *Loganiaceæ*, the order to which *S. nuxvomica* (Linn.) also belongs. In 1812 Waterton, the famous Wakefield traveller and naturalist, paid a special visit to British Guiana to obtain a supply of the poison, his object being to test its efficacy as an antidote in snake-bite. On his return to Wakefield he demonstrated its action as an antidote in the house of Dr. Hobson, of Leeds. Unsuccessfully, I may add. To-day we know that both curare and snake poison in one phase of their action at least are alike, for they both paralyse the ends of the motor nerves. Later, Robert Schomburgk, as the result of his travels, was able to say that the strongest poison as prepared by the Makushi Indians could be prepared from the bark of *S. toxifera* or *S. Schomburgkii*. Up to this period the precise manner in which curare acted remained a question of conjecture, and it remained for Claude Bernard to show, in 1857, that its action was to paralyse the motor endings in the muscles.

To return a little. Although Humboldt, Bonpland, and Robert Schomburgk had all been able to prepare an extract from species of South American *Strychnos*, which at least appeared to kill like curare, there yet remained an element of doubt as to this plant being the only really active agent entering into the composition of curare. There was further some reason for this element of doubt, because Richard Schomburgk (brother to Robert) published in 1879 a pamphlet in which he stated that the tribes of the rivers Amazon and Rio Negro do not employ a *Strychnos* species at all in the fabrication of their curare. More, Dr. T. L. Bancroft and Professor de Lacerda, of Rio Janeiro, till within the last few months maintained that curare did not owe its action to a *Strychnos*, and I shall refer later to the plants they believed were at least identical in action to those entering into the composition of curare. Thus it was left to be proved that a species of South American *Strychnos* had an action similar to the commercial curare. This was not an easy matter to settle, for it is most difficult to obtain a supply of any species of *Strychnos*. Four years ago I tried every possible source to get a supply at any cost, but all I could get was a very small quantity of the scrapings of a bark

(a) Read at the Therapeutical Society.

reputed to be *S. toxifera*. A few years ago a well-known German alkaloid maker sent a medical man to British Guiana to buy a supply of the plant, but after remaining some months in the Colony he had to leave without having effected his mission. The causes of the difficulty are many. The plant only grows in certain restricted areas not easy of access, and the Makushi are careful to keep the habitat of the plant a secret. Fortune favoured me at last, for early in 1903 I one morning received a large parcel containing blowpipe arrows tipped with curare, branches and leaves of *S. toxifera* (Benth.), the gift of Mr. J. J. Quelch, the British Guianian traveller. The blowpipe arrows had been presented to Mr. Quelch by a Makushi chief as a special mark of favour, and Mr. Quelch had himself cut the plant, which had been pointed out to him by the *peaimen*, or makers of the poison, as the plant they employ in fabricating the arrow poison curare. This plant grows on the Urali Mountain of the Kanuku Range, British Guiana.

To follow up the proof. I examined the arrows and found them tipped with a substance which possessed the usual curare action on the motor end plates. I sent a portion of the branches and leaves to Mr. E. M. Holmes, botanical referee to the Pharmacopœia Committee, and he was able to say that they were those of *S. toxifera* (Benth.). I next examined the bark pharmacologically, and found it to possess the curare action on frogs. At the time I happened to have a large supply of excellent male frogs of a weight from 43 to 30 grammes, and these I employed to ascertain the smallest dose of bark which would completely paralyse the motor ends and without the animals recovering. The frogs were pithed, and the main artery of one leg was tied in the usual manner of such experiments. The following may be taken as a type of the whole.

An infusion of the dried bark having been made, the one ten-thousandth part of a gramme (15.432 grains) of bark was injected into the dorsal lymph sac of a frog of 43 grammes weight (663 grains).

In 20 minutes—signs of motor weakness.

In 50 minutes—greater signs of motor weakness, preceded by tetanic spasms.

In 80 minutes—the motor paralysis is complete and the protected limb alone is uplifted when the skin of the poisoned side is stimulated by pinching or the application of weak H_2SO_4 .

Passing on to 15 hours after injection—no signs of recovery from the motor paralysis.

In 24 hours there is a little recovery from the paralysis, but it is soon found to be only a temporary recovery.

In 40 hours the protected limb alone responds to stimulation of the skin of its own parts. Stimulation of the poisoned areas is not followed by uplifting of the protected leg. In connection with the question of paralysis of sensory ends by curare this should be noted also. Heart exposed and found beating. On strong stimulation of the sciatic nerve on the poisoned side the muscles below contract. This point will be touched upon later.

Further I made an extract from the bark, dried it in the sun and examined it on frogs, and as may be inferred it acted like the imported curare. It has been stated that the leaves of *S. toxifera* are bitter, but this is a mistake. They are not bitter, and they contain no curarine. Insects feed largely on them. The very tiny twigs of the plant likewise contain no curarine.

In case that I might happen to be mistaken I sent portions of the plant to Bancroft and Lacerda, and they have been able to confirm my results.

In continuation of the proof, I prepared from the bark pure curarine and found it to exist there in the proportion of 5.28 per cent., and it answered all the tests, chemical and pharmacological, of that alkaloid. Thus one may now say that the chain of evidence is complete, and we owe this to the perseverance of an English traveller, Mr. J. J. Quelch.

The other chief alkaloid of *S. toxifera* is curine, but it does not paralyse the motor end plates, and it does not at the present moment interest us. The minimum

paralysing dose of curarine for every gramme weight (15.432 grains) of frog (0.0000027 grammes) is about the 1-250,000th of a grain. In 24 hours the frog recovers from this dose. The frogs were pithed, I should add. Unless one had actual experience of the potency of curarine, it would hardly be believed that doses so small as those indicated above could have any action at all. Pure curarine in a thin layer is yellow, and it can be obtained in rosettes and plates; but it is highly deliquescent and soon deteriorates, and a second attempt at crystallisation is attended with failure. It is often asserted by authorities that the salts of curarine are inert, but this is wrong. I prepared a salicylate of curarine and kept it for weeks, and found it at the end of that time to be relatively as active as the absolute alkaloid. It may be mentioned that the alkaloid exists in the bark as a sulphate, which is no doubt easily broken up; then why should it not be possible to form active salts outside the plant? Pure curarine is readily decomposed by damp, and the greater the purity the more readily does it decompose and deteriorate. It is highly soluble, and cold water readily removes it from the bark, but this is in some respects a disadvantage, for the bark can with the greatest difficulty be exhausted. I found, on examining a bark which I had thought to be freed from curarine by percolation, that when it was infused and a portion injected into a frog, 0.032 gramme, or about half a grain, caused motor paralysis in a 22.5 gramme frog (347 grains).

I must briefly refer to one or two points, although they hardly come within the title of my paper.

1. Does curare affect the sensory ends?

Although the experiments of Tillie and others point to a non-affection, I hold the opposite view. If the dose of curare be large or if the experiment be so arranged or can be so arranged, that the poison acts sufficiently long it will be found that a stimulus applied to the poisoned skin area will fail to bring about uplifting of the protected limb, while a stimulus applied to the skin below the point of ligature will be followed by uplifting.

2. Is curare a tetaniser?

Undoubtedly it is, and the tetanus is not due to asphyxia. Curiously enough, it is often mixed because it is a transient sign and it is unsuspected. In the warm-blooded animals tetanus is more evident than in frogs, but in them death is rapid. In the frog the tetanising action of curare is best seen if the animal be not pithed and if the dose be very large—say, a large dose of curarine. The animal is not unlike one affected by strychnine, except that the tetanus appears to be more limited and that it soon passes off and gives place to motor paralysis. The tetanising action of curare was, so long ago as 1812, remarked upon by Waterton, and he writes of its action on fowls: "Three minutes generally elapse before convulsions come on." He experimented on larger animals, and in an ox the traveller found that "his legs were convulsed and his head from time to time started involuntarily. The startings or *subsultus tendinum* now gradually became weaker and weaker." This naturally leads us to another question—the relationship existing between the Asiatic *Strychnos* (as represented by *S. nuxvomica*) and the South American *Strychnos* (as represented by *S. toxifera*). At first sight it would appear that the difference is one of kind, but when examined more carefully the difference between them is discovered to be one of degree only; and this difference may be stated briefly as follows:—The Asiatic species (*S. nuxvomica*) is first and foremost a tetaniser and only secondarily is it a paralyser of the motor end plates; while the South American species (*S. toxifera*) is first most marked as a paralyser of the motor ends, and this is apt to mask the secondary tetanising action.

Practical Application.—Curare has been employed in the treatment of chorea, convulsions due to any cause in snake-bite and in strychnine poisoning, and to prevent painful spasm attending the transport of the wounded in warfare. The dose is from 1-20th to $\frac{1}{2}$ grain by injection. The percentage of curarine in commercial

curare is about 9 or 11, and some contain very much larger percentages. As much as 51 or 52 grains of curare have been injected under the skin at intervals of a period of time extending over 22 hours. Curarine is too uncertain a drug to employ because of its liability to deteriorate. To produce the typical curare action, very large doses must be given by the mouth, because the substance is rapidly eliminated by the kidneys. Curare is taken by the mouth by the natives of British Guiana as a bitter tonic. If we examine the manner in which curare acts in relieving spasm we find that if the spasm has a peripheral origin then we may look for benefit from its use, but if the spasm originates higher up than its employment is founded only upon empiricism.

I believe that curarine in large doses paralysed the sensory ends and that curarine is a tetaniser, but that the tetanus is of a short duration and apt to be overlooked unless carefully sought for.

Touching on the practical application of the plant and its preparation, I think they are not of much use. Passing next to the consideration of other substances resembling curare in action, I found that snake poison resembles it closely and also delphocurarine, an alkaloid derived from *Delphinium scopulorum*, a ranunculoid plant of Mexico. Ditamine (from dita bark) and alstonine (from Australian bitter bark) also possess something of the curare-like action on the motor nerve-ends, as well as aconite. The Moors in Spain employed extract of aconite to poison their arrows, and at the present day the Hairy AINU uses aconite as an arrow poison. The thorny yellow woods of Australia are like aconite in some ways in their action on the motor nerve-endings.

For some years past I have been experimenting with diphtheria toxin on pithed frogs, with the artery of one leg tied. The object was to ascertain if the toxin, in its action on the nervous tissue, first attacked the junction of muscle and nerve. I found that the poison acted slowly in frogs, enormous doses acting 24 to 40 hours only after injection, and in several of my experiments I have been able to show and to prove to my own satisfaction that perhaps the toxin first attacks the point of junction. I am continuing my experiments with diphtheria toxin and with several vegetable substances, which may possess curare action, and hope to publish results next year.

SOME CLINICAL OBSERVATIONS ON NEW REMEDIES. (a)

By NESTOR TIRARD, M.D.,

Lecturer on Medicine, King's College Hospital.

AFTER some introductory remarks the lecturer said uricidine, or lithium citrate, with lemon juice and soda, had been recommended for gout; uric acid concretions, and rheumatism. Really it chiefly acted as a laxative and did not relieve the pain of gout nor dissolve uric acid concretions. Its dose was 1 to 2 drachms.

Urotropine, made from formaldehyde and ammonia, was said to be a diuretic which relieves cystitis owing to uric acid concretion and destroys typhoid bacilli in urine, but unless well diluted it may cause hæmaturia and sometimes strangury, albuminuria and abdominal pain, but these bad symptoms do not occur if each dose is diluted with 5 ounces of water. In cases of offensive urine with uric acid sand he found it remove the offensive smell and diminish the sand. Dose 5 to 15 grains.

Aspirin, or acetylsalicylic acid, is not better than salicylic acid, and often produces dyspepsia and profuse perspiration, sometimes diarrhoea. In headache from overwork in gouty persons it often relieves the pain and causes sleep, but the patient should remain in bed after taking a dose, because of the perspiration.

Dose 10 grains in compressed form, as it is very insoluble.

Mesotan, or mesoxyl ester of salicylic acid, is readily absorbed by the skin when applied with olive oil. It relieves the pain and stiffness of rheumatism when fever ceases. Sometimes it irritates the skin if rubbed on it, or if covered too thickly, or if mixed with water. It should be well diluted with olive oil and painted on with a brush.

Ovoferrin, made by heating iron torpate with serum albumen, increases the hæmoglobin. In a case of pernicious anæmia its use with 15 minims of liquor arsenicalis thrice daily increased the hæmoglobin 64 per cent. It must not be diluted till taken, or it may decompose.

THE COMPARATIVE VALUATION OF DISINFECTANTS.

By C. G. MOOR, M.A. Cantab., F.I.C.

SOME months ago (May 11th, 1904) the question was discussed in your columns as to the relative values of disinfectants, and being greatly interested in the subject I had hoped you would have published the results of the investigations you then proposed taking; but probably you have found the task to be herculean.

It is evident, however, from the many references thereto in the medical and analytical journals, that the question of the comparative efficiency of disinfectants is receiving considerable attention among medical men and sanitary authorities.

Comparisons of this character have been attempted with more or less success ever since we were in possession of pure cultures of pathogenic bacteria to work upon. Unfortunately, the various small details which must be closely observed in order to ensure success have only been discovered comparatively recently, and most of the results recorded in text-books must be accepted with great caution. The method published by Dr. Rideal and Mr. Ainslie Walker in the *Journal of the Sanitary Institute*, Vol. xxiv, Part III, embodies the details necessary for success, and has virtually been accepted as the standard process both by British workers and those on the Continent. This process consists in submitting cultures of any pathogenic organism to the action of precise dilutions of the disinfectant under specified conditions, at the same time running comparative tests with dilutions of pure phenol on similar cultures of the same strains of bacteria. In this way actual numerical valuations can be obtained in terms of phenol. This method was employed by the referees appointed by the German Court in a recent case in which Mr. Pearson, of Hamburg, took action against the Jeyes Sanitary Compounds Company, in respect to their claim to have discovered a disinfectant four times as strong as the product they had previously been supplying to Germany (and elsewhere) under the name of Creolin. They claimed that their new preparation, sold under the name Cyllin, was four times as strong as Creolin, and eleven times as strong as pure carbolic acid. The case was tried in the District Court at Hamburg, and the decision given in favour of Messrs. Jeyes, whose claim on behalf of Cyllin was thereupon upheld.

A further development of the practical utility of an exact standard method for the valuation of disinfectants is well illustrated by the new form of tender for disinfectants which (*Chemist and Druggist*, December 10th, 1904) is likely to be issued by the Borough of Chelsea, in which they invite tenders for so much "carbolic acid, or its germicidal equivalent."

As an illustration, if any manufacturer were able to produce a disinfectant having five times the efficiency of carbolic acid, he could tender 200 gallons of his particular make as an equivalent of 1,000 gallons of carbolic acid, and assuming that the proprietary article cost 2s. 6d. per gallon and the carbolic acid cost 1s. 6d. per gallon, the saving to hospitals or to the ratepayers would be exactly £50.

(a) Abstract of Paper read before the Therapeutical Society, Tuesday, December 26th, 1904.

This is a new departure of great importance, and while it will certainly save to the ratepayers, it will also ensure their having a disinfectant of real utility. Several of the better known disinfectant manufacturers have already succeeded in producing an article which is *strength for strength* decidedly cheaper than carbolic acid, and has the advantage of forming good emulsions with water. In addition the healthy competition that such a tender-form will create among manufacturers cannot fail to stimulate them to produce as efficient a disinfectant as possible; will make for the general good, and the terms of the tender will also make it impossible for any suspicion of undue influence to attach to any public official owing to his having considered it his duty to recommend his authority to purchase either this or the other preparation.

ALCOHOL

AS A FACTOR IN THE CAUSATION OF DETERIORATION IN THE INDIVIDUAL AND THE RACE. (a)

By W. McADAM ECCLES, M.S., F.R.C.S.,
Assistant Surgeon to St. Bartholomew's Hospital.

MR. ECCLES offered no apology for bringing forward again a matter of individual and national importance. As one of the witnesses before the Inter-Departmental Committee on Physical Deterioration, he had paid special attention to alcohol as a factor in producing such deterioration. In the term "alcohol" he would include all varieties of alcohol, and also the still more poisonous substances contained in many alcoholic beverages. By "deterioration" he understood a decline in the economic value of the organism produced by an actual change in cell constitution. It should be distinguished from "degeneration," which was rather a decline from morals, and the two conditions contrasted much in the same way as an objective sign did with a subjective symptom. The direct alteration in a cell might be demonstrated microscopically, and that produced by alcohol had been repeatedly so demonstrated. Alcohol acted in bringing about deterioration. This was almost universally admitted. It acted both directly and indirectly.

Direct action upon the individual varied enormously, and this on account of the personal equation of the subject. This personal equation obtruded itself in the way of age, environment, occupation, a nervous instability, and actual disease. Probably the younger the cells infused with alcohol the greater the harm impressed upon them. Hence the growing tissues of children were quickly deteriorated. He considered it probable that many instances of rickets occurring in children who were breast-fed were due to insufficient and abnormal mother's milk charged with small but repeated doses of alcohol. In old age alcohol was a potent factor in rapidly wearing out the human machine. The environment had a great influence upon the effects of alcohol in causing deterioration. The close connection between a craving for drink and bad housing, bad feeding, a polluted and depressing atmosphere, long hours of work in over-heated and often ill-ventilated rooms, only relieved by the excitements of town life, was only too self-evident, and the ravages of alcohol under such circumstances only too perceptible on all hands. It was just in these very factors of deterioration that a vicious

circle was apt to be set up. Bad housing and bad feeding created a desire for alcohol, and the money spent on the drug left less for rent and proper comestibles. The meagre knowledge of cookery possessed by young women brought up in towns led to much inducement for both their husbands and themselves to frequent the public-house for the purpose of obtaining alcohol to give them the sense of having secured a good meal. Want of fresh air deprived the drinker of the oxygen needed for the destruction of alcohol. Fatigue and excitement both engendered a thirst for alcohol, and through it deterioration. In connection with occupation it appeared that the higher and more intricate the character of the work undertaken by a man, the more rapid were the deteriorating effects of alcohol upon him. The drudgery of many female lives made women have recourse to alcohol. The fact of deterioration by alcohol was abundantly proved by the statistics of those life assurance offices which separated the "lives" of moderate drinkers from those of total abstainers, the greater longevity of the latter being distinctly marked. The indirect action of alcohol in the production of deterioration was even more pronounced than the direct, and was particularly so upon child-life. Both before and after the birth of the infant, alcohol in the mother told upon it. Whatever view might be held with regard to heredity, there could be but little dispute that the alcoholic mother neglected her offspring, and that the effects of such neglect were disastrous. If the mother as well as the father were given to alcohol, the progeny would deteriorate in every way, and the future of the race would be imperilled. The facts deduced to show that alcohol caused deterioration were worthy of close consideration with a view to the eradication of a force tending to undermine the efficiency of the nation.

Lunacy Department.

ASYLUM REPORTS.

Glasgow District Asylum, Woodilee.—During the year the number of patients under care and treatment was 1,177; the admissions numbered 292—162 males and 130 females. The number of patients discharged recovered was 138, while 72 patients were discharged "not recovered", the deaths numbered 86—57 men and 29 women. In 31.8 per cent. of the patients admitted there was a history where alcoholic excess played the chief part in the causation of insanity. Insanity as the result of venereal disease occurred in 21 cases, while general paralysis was the form of insanity found in 33 admissions—29 men and 4 women, and was the cause of death in 22.7 per cent. of all the deaths that occurred among the male patients of the asylum during the statistical year. Dr. Marr thinks the reason why the history of venereal disease does not occur in the clinical experience of all such cases is that many of these cases, before reaching an asylum, have migrated from one hospital to another, and the clinical symptoms of the disease have disappeared in course of time, or as the result of desultory treatment, since such patients do not often submit to the lengthened period of treatment required by the medical authorities. In short, he says, given venereal disease, the vices that attend residence in

(a) Abstract of a Paper introductory to a discussion at the Society for the Study of Insanity held in the rooms of the Medical Society of London, 11 Chandos Street, W., on Tuesday, January 10th, 1905.

a large urban community are sufficient, if indulged in, to incite this fatal form of nervous degeneration. We still, however, believe that there are cases of general paralysis of the insane, where venereal disease has never existed, and we think that in this and certain other asylums too much is made of this and also alcoholic excess as a cause of insanity. The percentage of recoveries, calculated on the number of admissions, was 47.2. This is the largest recovery-rate recorded for twenty years. One thing which deserves most favourable notice at this asylum is the reception house. Since the opening 373 patients have been admitted to its wards, and of this number 130 have been discharged recovered, without having to mix with patients in the main asylum. An excellent new laboratory for clinical and pathological work has been opened. It is provided with rooms for microscopical, bacteriological and chemical investigation. In addition, there are mortuary and *post-mortem* room, accommodation for special research work, a room for photographic purposes, and a museum and library for the medical staff. We cannot, however, but think that such an elaborate laboratory much exceeds the requirements of a district asylum, especially in Scotland, where all the asylums can utilise the Scottish Asylums' Laboratory. From the small amount of original work done in the past by asylum pathologists, and as they are frequently only birds of passage, only waiting for a better appointment owing to the small remuneration asylums can afford to pay them, we think much better and more useful pathological work could be done by each asylum pathologist working under the guidance of the director of a central laboratory such as Scotland now has. A nurses' home, which will accommodate 110 nurses, has been opened, and much progress has been made in the training of nurses in this asylum. The nurses require to pass an educational examination during a probationary period of three months. After three months' training they must show evidence of the sufficiency of their training by passing examinations necessary for registration as nurses with the Local Government Board, and for obtaining the certificate of the Medico-Psychological Association. On the strength of this evidence, nurses will be admitted to one of the district hospitals of Glasgow Parish Council for a further period of training for one year. This we consider a most excellent arrangement. Much interesting reading will be found in this report, which is well illustrated, and throughout there is marked evidence of progressive and scientific management.

Transactions of Societies.

NORTH-EAST LONDON CLINICAL SOCIETY.
MEETING HELD THURSDAY, JANUARY 5TH, 1904.

DR. R. MURRAY LESLIE, President, in the Chair.

DR. A. J. WHITING opened a discussion on THE MEDICO-LEGAL ASPECTS OF ALCOHOLISM. The speaker held that, from the medico-legal standpoint, alcohol was only of interest when it was taken in sufficient quantities to exert a poisonous action, although chronic alcoholism might have some forensic importance, as, for example, in affecting the memory or the truthfulness of a witness, yet the chief interest centred around acute alcoholism, especially in the matter of

diagnosis. This might be conveniently divided into two stages, the *pre-* and the *post-comatose*. The only pathological conditions which might be confused with the pre-comatose stage of acute alcoholism were post-epileptic automatism, from its apparent irresponsibility of conduct, locomotor ataxy, from its staggering gait, and general paralysis, from its articulation, incoherence, and grandiose ideas.

It was after the onset of coma that the real difficulties in diagnosis began, and medico-legally, this was the most important practical part of the subject. The importance of a correct diagnosis was clearly shown by those instances, of not very frequent occurrence, in which persons have been considered by the police to be suffering from drunkenness, and have been left in the cells to "sleep it off," with the result that they were found later to be dying from some other condition. The pathological states which might simulate profound alcoholic intoxication were then classified thus:— (1) Coma from toxic doses of some medicinal agent, such as opium, belladonna, carbolic acid, &c.; (2) coma from poisons other than drugs, such as in uræmia, diabetes, and asphyxia from poisonous gases; (3) coma following convulsions; and (4) that resulting from some cerebral lesion, whether minute or gross. Before a logical diagnosis could be arrived at, three difficulties had to be faced: (1) no history of the patient's previous health was usually obtainable; (2) alcohol was frequently administered by sympathetic onlookers, so that the odour of alcohol in the breath was of little value; (3) two or more conditions might be combined in the same individual. A differential diagnosis was then given of acute alcoholism from other conditions, special stress being laid upon the pupillary symptoms, the depth of the stupor, the temperature, the presence of paralysis, and the question of external injuries.

The PRESIDENT referred to the bearing of chronic alcoholism upon such matters as the validity of wills, and to the necessity of the enforced treatment of chronic inebriates in institutions.

DR. C. R. SALISBURY alluded to the moral deviations in regard to truthfulness which was such a frequent symptom in chronic alcoholism.

DR. J. W. HUNT advocated caution in a medical man committing himself to a diagnosis in doubtful cases of unconsciousness, and he remarked upon the wisdom of acting as if such were all serious cases. He thought that in 30 per cent. of the cases of cerebral hæmorrhage in his experience the onset was not sudden.

DR. R. F. TOMLIN described a case of double pneumonia in which there were automatic actions simulating those following upon an epileptic attack.

DR. T. D. MANNING especially alluded to the circulatory changes in the various sorts of intoxication.

DR. H. F. STAUNTON thought that, as a rule, the coma in a surgical case was not so deep as in a toxic case.

DR. A. E. GILES referred to the occasional difficulty of diagnosing between the lesser degrees of alcoholism and the earlier stages of mania.

MR. HERBERT CARSON emphasised the difficulty of diagnosing between acute alcoholism and cerebral compression following head injuries, especially fractured base; it was not so great in cases of simple concussion. He also insisted upon the possibility of the presence of a subdural hæmorrhage of traumatic origin without any external wound.

DR. WHITING, in replying, thought that it was necessary to weigh all the facts in any individual case, and not to trust to any one symptom or sign.

ULSTER MEDICAL SOCIETY.

MEETING HELD ON THURSDAY, JANUARY 5TH, IN THE MEDICAL INSTITUTE, BELFAST.

The President, DR. WILLIAM CALWELL, in the Chair.

PROFESSOR SIMS WOODHEAD, of Cambridge (who had come at the invitation of the Ulster Branch of the

British Medical Temperance Association), opened a discussion on the subject of

ALCOHOL AS A PROTOPLASMIC POISON.

Dr. WOODHEAD, who received a very hearty greeting from the Society, began by giving his reasons for considering alcohol to be such a poison, doing harm of necessity. He contended that experiment showed that the general action of alcohol on protoplasm was harmful, and the more highly organised the protoplasm was the more harmful the alcohol proved to be. That the action of alcohol was gradual was shown by the gradual extinction of the light of phosphorescent bacilli, whose functional activity is interfered with by a 2 per cent. solution of alcohol, and destroyed by a 6 per cent. Fatty degeneration was produced by small doses of alcohol on more highly-developed, and specially on young, protoplasm. There are marked resemblances to phosphorus poisoning. It was best seen in the liver, but exactly the same process took place in the heart, the degeneration being in proportion to the amount of toxic material. This degeneration is found in the heart at the termination of the peripheral vessels. Dr. Woodhead maintains that alcohol must be looked on as a cumulative protoplasmic poison, and it acts on the heart in the same way as many diseases do, and therefore must increase the result brought about by them, if given during their progress. We are perhaps inclined to pay too much attention to the higher cells, and not sufficient to other tissues, in which the same changes are probably going on, as, for instance, the changes in the connective tissue of the blood-vessels. Wherever we have degeneration in higher tissues we get calcification, and Dr. Woodhead held that the same form of degeneration in blood-vessels was often due to alcohol. After referring to the use of alcohol in various diseases, Dr. Woodhead dwelt on its peculiar action in lead poisoning, which is greatly facilitated by its presence in the organism, abstainers being seldom attacked. He then discussed immunity and alcohol. In five diseases in which immunity is clearly produced in the course of the disease, namely, anthrax, hydrophobia, tuberculosis, diphtheria and tetanus, alcohol markedly interferes with the production of immunity, so that it is difficult or impossible to produce when alcohol is being given. He concluded, therefore, that in those diseases alcohol must as a rule do harm.

Professor BYERS said that many of the scientific points we were not in a position to discuss, but practitioners might well consider how far the views set forth agreed with the facts as observed in practice. He pointed out the extraordinary change in recent years as regards the use of alcohol in pneumonia, puerperal fever, and after operation.

Professor LINDSAY was not in complete assent with Dr. Woodhead. He thought in the revulsion of feeling against the over-use of alcohol the pendulum might swing too far the other way. He thought alcohol was not a necessity, that the proportion of people who could abstain with advantage was probably a large one, and that there was no disease where alcohol was indicated as a routine medicine. But he was doubtful about applying laboratory experimental calculations to clinical work. Clinically he was very sparing in its use, but he believed that in some cases, with weak circulation, and in some nervous conditions with sleeplessness, alcohol was a valuable remedy. Also he used it in some cases as a tonic, but on the whole he thought we might more profitably dwell on its dangers than on its uses.

Dr. KEVIN referred to the increase of insanity, and its connection with alcoholism.

Professor MILROY discussed some of the experiments mentioned by Professor Woodhead, and thought that alcohol should be classed as a narcotic poison.

Dr. JOHN CAMPBELL considered the views of Dr. Woodhead on the whole correct, but there were two sets of cases where he thought it might be used with advantage, first, in hopeless cancer cases, where it helped the action of morphia, and secondly, in septic

infection, where small doses often overcame restlessness even better than morphia.

Dr. ROBB said that he had treated about 3,000 cases of typhoid fever in the last four years, and he did not think he used alcohol in 5 per cent. of them. In those few cases, however, he was not inclined to give it up, as he thought it was occasionally very useful. He had about 100 diphtheria cases a year, and alcohol was practically never used in them.

Dr. MITCHELL discussed the withdrawal of alcohol in cases of accident to alcoholic patients, which he thought dangerous.

Dr. BURNS and Dr. KILLEN having also spoken, the President wound up the discussion with a few remarks on the use of alcohol by the aged, which he did not think at all so necessary as some previous speakers.

Professor WOODHEAD having replied, a hearty vote of thanks to him for his visit was passed on the motion of Professor SYMINGTON, seconded by Dr. JOHN CAMPBELL.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, JANUARY 8th, 1905.

THE TROUBLES OF THE WISDOM TOOTH.

THE wisdom tooth develops generally between the ages of sixteen and twenty-five, and in some cases much later, at forty, fifty, or even sixty years. Numerous are the troubles caused by it, more frequently observed in the male sex, also seeming to have a certain preference for the left side, says Professor Morestin. The teeth of the lower jaw alone are affected; the wisdom teeth of the upper jaw never give rise to any accident.

The molar is found in the body of the maxillary bone covered by a thin osseous coating and ready to take its place in the mouth. This it does by pushing forwards the second large molar, and as the space between that tooth and the ascending branch of the maxilla is very limited, it has to work its way up by curving now to the right, now to the left, until it pierces the gum and finally establishes itself. If matters pass quietly the individual will suffer but slight pain; the gum may be a little swollen, and a little fever may be observed. But in the majority of cases these symptoms are but the commencement of grave troubles; the gum becomes more and more painful, because the upper wisdom tooth, which is always the first formed, presses on it each time the mouth is shut, or during mastication. If infection set in the phenomena become greatly aggravated; the temperature runs high, and the general symptoms mark the intensity of the lesions, or the pus invades the socket, and very tenacious dental arthritis is the result, or by the two small conduits which united the roots of the tooth to the dental canal, creating osteo-myelitis of the maxilla—a very grave affection; or it attacks the muscles, producing myositis of the pterygoid muscle, giving rise to contraction or trismus of a more or less permanent character. Sometimes the pus invades the mouth or the pharynx, producing a phlegmon, which may provoke suffocation or asphyxia. The osseous lesions suppurate for a very long time, and in the case of osteo-myelitis, for instance, necrosis of the bone may result, followed by perforation of the cheek. But all these accidents, however grave, are out-distanced by lesion of the venous plexus of the region; here thrombosis of the veins may produce an abscess of the brain, meningitis, and death. Consequently active treatment is called for in cases of painful cutting of the wisdom teeth. If the symptoms are slight and only due to tension of the inflamed gum, it will be sufficient to apply the thermo-cautery or incise the gum with a lancet. If, on the contrary, there already exist evident signs of dental arthritis, the tooth must be immediately extracted, otherwise some of the above accidents may occur. According to Professor Morestin, sufficient attention is not paid to development of the wisdom

tooth, as in many cases the sufferings of the patient are attributed to some other cause, such as neuritis, rheumatism, &c.

THE TREATMENT OF OZENA.

The treatment of this very troublesome affection has given rise to many therapeutic combinations, which, being tried, were found to be more or less wanting: camphor, iodoform, formol, thymol, menthol, &c., were recommended and are still used, but a permanent cure is difficult to obtain, many factors entering into the nature of the affection.

Dr. Bobone claims to have obtained great success with the use of petroleum, which he considers in the dual point of view as a bactericide and a stimulant.

The solution he uses is as follows:—

- Refined petroleum, 1½ oz.;
- Nitrate of strychnine, ¼ gr.;
- Oil of eucalyptus, 1 drop;

After antiseptic irrigation of the nasal cavities to remove all secretion, a piece of cotton wool steeped in the solution is applied by means of a stylet to all the surface of the fossæ once a day. In a short time all offensive odour disappears, and the mucous lining assumes a healthy appearance.

Another effective treatment consists in insufflation of the following powder:—

- Collargol, 10 grs.;
- Sugar of milk, 3 drs.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, January 7th, 1905.

At the Gesellschaft der Aerzte, Hr. Orth spoke on EMPHYSEMA OF THE LUNGS.

He said that in the rare cases in which the disease occurred in infants, it was not inherited (congenital) as there was no breathing during intra-uterine life. But there was an inherited disposition that could lead to emphysema after birth, and this was perhaps to be explained by a change in the elastic properties of the lung. Air pressure, especially the expiratory, played a part in the origination. Inspiratory effort could only act in this way when it was freed. As regarded the expiratory pressure, it was to be said that it could only act on the part not subjected to pressure. Observation on trumpeters showed that expiration alone could not cause emphysema, as they were not all asthmatics: a disposition to it must be added. There was also a partial emphysema.

Hr. Heubner asked whether the rigid thorax observed in infants and later was due to emphysema, or the other way about. Hr. Orth thought the changes in the lungs were primary.

Hr. Lesser mentioned the relationship between eczema and asthma.

At the Laryngological Society, Hr. Peyser related a case of

COCAINE POISONING.

A girl, æt. 18, had taken a gramme of cocaine hydrochlorate. The first serious symptom showed in an hour and three-quarters: sleepiness, very frequent pulse, complete dilatation of the pupils, clonic spasms of the extremities, opisthotonos, protrusion of the tongue, &c. The stomach was washed out and a hot bath given, with cold douches. Eight grammes of nitrite of amyl appeared to have a favourable effect. A state of excitement lasted for a longer period than the other symptoms.

At the Medical Society the subject of MAMMARY CANCER

was introduced by Hr. Lassar. He showed a patient with a cancerous ulcer that had arisen after operation for recurrence, and that would not heal. After the X-rays had been applied a smooth cicatrix formed in a short time. He thought the X-rays were particularly useful in these ichorous ulcers that would not heal. They also came into consideration for the superficial tumours lying in the skin; but no result need be expected in the case of deeply lying carcinomata. The treatment should not come into

rivalry with ordinary procedures, but it might be useful in cases of inoperable mammary cancer.

Exc. v. Bergmann showed three women with mammary cancer of unusual form: (a) one with enormous dissemination in the skin, so that small nodules could be seen, or better still, felt, even down to the lumbar region; (b) extraordinarily marked infection of the lymph vessels of the chest, neck and upper arm; (c) one similar to the foregoing, and also a board-like hard infiltration in the neck, which was diffuse, not knotty, and gave rather the impression of a deep phlegmon.

Hr. Blaschko spoke on

SYPHILIS AS A PROFESSIONAL DISEASE.

He said he had had to treat twelve medical men suffering from syphilis contracted in the course of their calling. Most of the primary effects were on the fingers, and they had been treated as whitlows, until the torpid appearance and glandular swellings and exanthem had pointed to the true character of the disease. Once the primary disease was on the face, which had been scratched before the infecting material came into contact. In many cases the primary disease on the hand was very small, and it healed very rapidly; in one case there was no primary affection, so there must be a syphilis without primary disease, the infection material passing directly into the blood; an insect bite might possibly aid infection.

Infection of medical men took place in two ways: (a) from operation in syphilitic tissue such as buboes; (b) from contact with a sore already present. One case was that of a pathologist who had dissected a body covered with a syphilitic exanthem within twenty-four hours of death. There was no absolute protection. The surgeon should perform every operation and make every gynecological examination, as if the patient were syphilitic. Vaginal injection should be made, and in suspicious cases a finger stall should be used. The smallest wound should be looked after. Many of them were the consequences of too vigorous scrubbing with brushes and disinfectants. If the skin was delicate disinfection might be limited to washing with hot water and marble soap. If thorough washing were performed after touching suspicious material, our hands would not be so readily bearers of infection, even if excessive disinfection was not resorted to before the contact. Rubber gloves also might be used.

If rhagades were present they should be bathed with a 2 or 3 per cent. nitrate of silver solution and then sticking plaster or collodion put on. If with every care a wound was infected during operation, it should be flushed with water and dabbed with iodide or peroxide of hydrogen, or cauterised with the thermo-cautery.

The pessimistic conception of this disease led many surgeons, especially in their earlier years, to a too frequent course of mercury. This was not proper; he would use mercury only where disease was present; he was therefore opposed to the chronic intermittent administration of mercury in the first years of the disease.

The twelve cases were not particularly severe. It was not true that cases of extra-genital infection were specially severe.

Regarding the question as to how long a surgeon should refrain from work, naturally he must do so so long as the diseased part was capable of causing infection. In intervals free from recurrence, even if the mucous surface were diseased, nothing stood in the way of his following his employment.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, January 7th, 1905.

LYMPHANGIOMA CAVERNOSUM WITH CHYLORRHEA. At the Gesellschaft, Paul Albrecht demonstrated a case of lymphangioma cavernosum with chylorrhœa. The swelling had commenced some six years ago

over the right femur, extending into the groin. The surface was white and soft, and over the surface of the greatest prominence there were large vesicles averaging about the size of a pea, which emitted a clear fluid. If the patient took fatty food fleshy warts appeared on the surface, in the centre of which yellow colouring matter was observed. Tests with sesami oleum and alkanna root failed to demonstrate its chylous nature, but the presence of sugar, fat, and albumen gave undeniable proof of its presence. Within the last two weeks a similar swelling has commenced in the left groin. Neumann reminded the members of a similar case that he had exhibited to them two years ago. In that case he administered different colouring matters by the mouth, which acted on the lymph, giving a similar hue one and a half hour after. Albrecht's case differs in this respect, as he seems to have failed to obtain this colouring in the lymph. In my own case it may be remembered that Eiselberg extirpated the white swelling, and found the entering lymphatic vessels as large as goose quills. Franck said he had a young man some time ago who came to him with prominent lymphatic varicose ducts in the right leg, extending from the foot to the groin. Where the varix was present, when opened it was found to contain a small quantity of milky fluid. Eiselberg said that he had now seen two cases of lymphangioma with a considerable discharge of milky fluid. The therapy of this disease does not seem to meet with much success, but the earliest and most reasonable to recommend is the Paquelin treatment.

Weinlechner briefly recounted the history of a case that came under his own observation in the form of a large cyst which extended from the arm-pit to the pelvic bones.

Riehl next entered into the pathology of the disease and described the origin of the morbid changes as a malformation, probably hereditary, in the position of the lymphatic vessels, or in other words a lymphatic nœvus, which commences at first in a small area, and extends along the endothelium increasing the lymphatic vessel until a cyst is finally produced.

The history of the case before us admits of this interpretation: commencing six years ago, it gradually increased, and invaded the neighbouring structures, until the whole leg was involved with cystic formation of chylous matter. The chylorrhœa in this case is more prominently demonstrated by the inguinal lymphatic vessels of the left side of the pelvis becoming involved from the same anomaly in the anatomy as existed in the right side. Albrecht pointed out the difficulty of accepting the theory of a lymphatic nœvus by repeating the patient's history, that the cystic tumour in the left inguinal region was only discovered a few weeks ago, and that the skin covering the cyst was found to be in a normal condition.

SPINAL ANALGESIA.

Silbermark commenced his promised lecture on 200 cases in which he had operated with the assistance of this new spinal analgesic, for some time practised, in Mosetig's wards. After a careful description of the *technique* to avoid failure, he said cocaine must not be used, but "eukainia," or best of all "eukainiss," should be administered. A 3 per cent. solution, and freshly made, should be injected in doses of 10 cubic centimetres at a time. If the patient be under 16 years of age two centimetres of the 3 per cent. solution may be enough. If the solution be three days old the power and duration of the analgesic effect is greatly reduced; in this case the dose would have to be correspondingly increased. In this way Silbermark had given very large doses without any bad effects. The duration of the analgesia lasts from five minutes to one and three-quarter hour. Position has much to do with the modification of time, as the perinæum and genital organs never exceed five minutes. The loss of sensation commences in the following order:—1, pinching or nipping; 2, stabbing or pricking; 3, loss of temperature sensation; and 4, finally all clinical irritation.

The analgesic limit in the trunk seems to be across the umbilicus. A drawing of the perinæum in imperfect cases gives the patient a feeling of pressure; although a cut may be felt as a cut, or a tear as real, no pain is associated with the act. The sensation returns first at the point of the toes, next across the line of the umbilicus, and lastly in the peritonæum. No toxic symptoms such as bulbar irritation were witnessed, although muscular quivering has been observed, which at once disqualifies the patient for such a method of operation—in this case chloroform should be resorted to, and a few drops are quite sufficient to produce anæsthesia. Any age between 11 and 69 years may be put under this method, the younger being affected more rapidly and more frequently with vomiting and muscular twitching, with transitory collapse, relieved by raising the pelvis, although the opposite is often effectual; alcoholics are usually the most difficult. After the operation no headache or untoward symptom has been observed, neither is the pain in the wound more painful than under chloroform. Retention of urine never exceeds three days when it does occur; post-operative temperature 38° Cent., and feeling quite well in two or three days.

The eucaïne treatment is contraindicated under ten years of age; relatively dangerous between 11 and 16, as well as in the alcoholic. Tabes, arteriosclerosis, and allied conditions are well adapted for this method of operating. When vomiting does occur the danger is *nil*, as the functions of the body are little disturbed; hence he concludes that spinal anæsthesia is the best.

The Operating Theatres.

ROYAL EAR HOSPITAL.

RADICAL MASTOID OPERATION.—Mr. MACLEOD YEARSLEY operated on a girl, at 14, who had been sent up to the hospital by Dr. Biggs, of Battersea. The history of the case was as follows:—Eight years ago she had a sudden acute attack of right middle ear suppuration. Her mastoid was opened at St. Thomas's Hospital, and a portion of the right internal jugular vein removed. This treatment appears to have had a satisfactory result until three years ago, when, during the course of a cold in the head—to which she was very subject—a foul discharge appeared, and has continued ever since, with occasional attacks of pain. On examination, a large semicircular scar was found over the mastoid process, and a three-inch cicatrix at the lower part of the neck along the anterior border of the sterno-mastoid. The membrana tympani was the seat of a large posterior perforation, and granulations could be seen through it within the tympanum. Both tonsils were considerably enlarged, and there was a pad of adenoids in the naso-pharynx. The patient was placed under chloroform and an incision made through the original scar over the mastoid, the auricle with the membranous meatus turned forwards, and retracted by a strip of gauze passed through the meatus. On detaching the periosteum a hole about the size of a sixpence was seen in the bone, its edges to a certain extent rounded by repair. This led into the antrum, which was full of flabby granulations and *débris*; the bridge of bone between this hole and the meatus was removed with the chisel and gouge, the remains of the membrane with the malleus and incus were cleared away, and the whole antrum, attic and tympanum thrown into one cavity. It was then found that the facial nerve was bare for a part of its course in the Fallopian aqueduct. The granulations which filled the antrum and tympanum were curetted, and especial care taken to thoroughly curette the

entrance to the Eustachian tube. A square flap was then cut from the upper and back part of the cartilaginous meatus, the cavity was carefully dried and packed with iodoform gauze, the auricle readjusted, and the wound sutured in its entirety. Mr. Yearsley said that this case was evidently one in which the radical operation would have probably been the wisest course when the mastoid was first opened, but it must be remembered that the time-honoured Schwartz operation was the only one known to general surgeons until quite recently. It must, however, be borne in mind, he thought, that in cases of acute mastoid suppuration, especially when uncomplicated, simple opening of the mastoid sufficed in the majority of cases; this case, however, was evidently complicated with some phlebitis of the internal jugular vein, for part of that structure had been explored at the original operation; at the same time it was interesting to note that no signs had been found at the present time of any implication, recent or remote, of the lateral sinus. It would be noted, he remarked, that there was a clear history of adenoid growths. It was possible that these were originally responsible for the ear disease, and it was surprising that, after opening the mastoid, the original operator had not thought fit to remove them; had he done so the tendency to frequent colds exhibited by the patient, which no doubt led to the recrudescence of the discharge, might have been prevented. In that case simple opening of the mastoid might have been sufficient, and the patient need never have come to the operating table again.

The adenoids and tonsils, he said, would be removed under gas during the following week.

TOTTENHAM HOSPITAL.

OPERATION FOR INTESTINAL OBSTRUCTION IN A WOMAN OF ADVANCED AGE with an interesting history.—Mr. H. W. CARSON operated on a woman, æt. 79, who had been admitted with the following history:—Fifteen years ago she had had her right breast removed for scirrhous carcinoma; this was followed by two recurrences, both of which were successfully operated on by removal. She remained in good health until four months ago, when she was admitted to the hospital with strangulated femoral hernia on the left side. At the operation for this condition the sac was found to contain a Meckel's diverticulum. She remained in good health for a month, when she was once more admitted, this time under Mr. Carson, and with intestinal obstruction. A definite tumour could then be felt in the left iliac fossa. Laparotomy was performed, and the cause of obstruction proved to be a malignant growth of the descending colon; the growth was fixed outside the abdomen, and the proximal part of the intestine drained by a Paul's tube. Ten days after, the growth was excised and the divided ends of the colon joined by end-to-end anastomosis. This was followed by an interval of six weeks' comparative comfort; she was then once more admitted with intestinal obstruction. Nothing could be felt in the abdomen except a great deal of resistance and some definite hardness underneath the left rectus abdominis. Frequent vomiting was a marked feature of the onset at the present operation. The abdomen was opened, and it was found that the lower part of the ileum was fixed by adhesions resulting from the previous operations, and that for seven inches the lumen was entirely obstructed. The adherent portion was rapidly freed, but owing to its

stenosed condition it was found necessary to excise it, and seven inches of the intestine were removed, and the ileum re-united by end-to-end anastomosis, a Murphy's button being used. Mr. Carson said that the interest of the case lay in the recurrence of malignant disease so many years after the removal of the initial lesion. It was difficult to say whether it was a case of recurrent carcinoma or whether it was an entirely new manifestation. The course of the operation for removal of the intestinal growth gave an opportunity of enforcing the necessity, in cases of obstruction associated with distension above the stricture by faecal accumulation and gas, of preliminary drainage before an attempt is made to remove the growth by resection. In the present operation distension above the obstruction was so slight, and the necessity of saving a patient of such advanced years the risk of a second operation, influenced him in the course he adopted of immediate enterectomy and anastomosis. He remarked that although as a rule he much preferred to do end-to-end anastomosis by simple suture, he chose Murphy's button in this case with a view to reducing the length of operation as far as possible. He drew attention to the extraordinary vitality shown by this patient, who, at the age of seventy-nine, had undergone three severe abdominal operations within four months.

The patient passed the button on the fifteenth day, and made an uninterrupted recovery.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, JANUARY 11, 1905.

THE HOSPITAL, THE HOSPITAL FUNDS, AND THE ROYAL ORTHOPÆDIC HOSPITAL.

In the *Hospital* for December 31st, the editor considerably inquired if we knew the laws of the constitution of the Hospital Sunday Fund. It was with a precise knowledge of the representative character of that body that we wrote. It is true that the Council consists of fifty clerical or lay members in addition to the committee of

distribution and officers who are members by virtue of their position. Among the fifty members, however, we fail to find the name of any single representative of the small hospitals. The large hospitals, on the other hand, are abundantly represented by chairmen and other honorary officials, and by members of their medical staffs. The Council, thus constituted, confirms the report of the Distribution Committee, which is the real controlling power. The Committee for 1904 was under the Presidency of the Lord Mayor. It contained a physician and a surgeon from the great hospitals, and six others, one of whom was Sir Sydney Waterlow, a gentleman whose aversion to the small hospitals has, we believe, never been concealed. Under such circumstances, we contend that the case of the small hospitals was not likely to be fully considered on their individual merits. In other words, the constitution of the Hospital Sunday Fund is defective because it has no representatives of the small hospitals either upon the General Council or upon the Distribution Committee. Now, as Sir Henry Burdett appears willing to tell us so much about the working of the Hospital Sunday Fund, may we ask where are the minutes of evidence upon which the Council acted in the case of the Royal Orthopædic Hospital? Were the objections of the minority of governors against the sale of their site adequately laid before the Committee of Distribution? If not, why not? As we asked last week, "Did they know and not care, or did they not know and not care?" Or did Sir Sydney Waterlow, whose acquaintance with City men and City ways is not less exhaustive and particular than that of Sir Henry Burdett, agree with that gentleman that the names of such financiers as Mr. Harry Marks, Mr. Head, and Major Ricarde-Seaver were sufficient to guarantee wise dealing with the valuable site that once belonged to the Royal Orthopædic Hospital? The contention of the Hospital Sunday Fund that they did not advise sale falls to the ground in the face of the personal evidence to the contrary by one of the hospital surgeons, a man of unimpeachable honour. Besides, they advised amalgamation, which, backed with the leverage of grants, comes to much the same thing. In any case, there is no attempt to deny that the King Edward Fund pressed amalgamation on the Royal Orthopædic Hospital. The public are entitled to ask if that policy was adopted with a full knowledge of the facts of the case. If so, where are the minutes, and what is the explanation given by the King's Fund for advising sale at a price £12,000 below that eventually obtained? The £12,000 of which Sir Henry Burdett speaks so lightly was saved to the charity by the opposition of the determined minority, who faced the majority that sprang up round Mr. Marks after his first appearance on the scene in 1898. The affair resolves itself into the question whether the Funds are going to enforce any particular policy on a given hospital regardless of economic consequences? Where do the Funds intend to

draw the line? Are they to enforce certain views held by some of their leading philanthropic members, or are they to act on well-considered and clearly defined principles in their attempt to control the management of the medical charities? Piecemeal work in this latter direction will be worse than none at all. The King's Fund pressed the sale of their former site on the Royal Ophthalmic (Moorfields) Hospital, a step that was followed by financial ruin. Why did they not press amalgamation on the Royal Ophthalmic Hospital as they have done on the Royal Orthopædic and the City Orthopædic. With the fate of their predecessors before them, the City Orthopædic will do well to shut their ears to the blandishments of the Funds. The Sunday Fund made in 1904 an award of £1,600, and in 1903 the King's Fund one of £2,000 annual grant and £2,500 donation to the Royal Ophthalmic Hospital to eke out bankruptcy due to the sale of an enormously valuable City site. Did the Funds originally investigate the facts before advising or approving that particular sale? If not, again, why not? It is surely not asking too much that the Funds should state to what extent they assert their right to control the actions of individual charities and that they should make public the grounds upon which awards are made or withheld. Further, we think the constitution of the Funds, and especially of their Distribution Committees, should be widened, so as to include representation of all medical charities, great and small. There should also be a right of public appeal in the case of a non-award. As there seems to be some misapprehension of our motives in certain quarters, we may conclude by saying once again, emphatically, that we are second to none in our admiration of the honour and the high aims of the Hospital Sunday and the King Edward Funds. Indeed, were it not for our profound trust in the unerring tact and justice of the Royal Family, who are so intimately concerned with these great modern philanthropic enterprises, it is probable these articles would never have been written. As it is, although we may not succeed in obtaining any adequate published answers to our contentions and suggestions, we nevertheless feel confident that the era of more perfect and, from our point of view, of fairer administrative justice will be speedily established in the Funds.

YOUTH AND INTELLECTUAL ENERGY.

ROBERT LOUIS STEVENSON, who would himself have remained young had he lived to a hundred, always maintained that the young deserve our respect equally with the aged. Each period has its own message to the world, and each deserves its measure of respect, but the disproportionate respect we are accustomed to pay to age is, he used to suggest, like that paid to sex, the expression of pity by the strong for the weak. However that may be, we think there is a tendency to overlook the important part played by young men in the intellectual life of their time. Pitt was Chancellor

of the Exchequer of England at twenty-one, and Byron wrote "Childe Harold" at twenty-three. In the realm of poetry, indeed, the preponderance of the work of youth is more generally admitted than elsewhere. Few poets have achieved fame who did not win their first laurels under five-and-twenty, and many of the greatest—Chatterton, Byron, Shelley, Keats, to mention no more—died in comparative youth. The field of science, and more particularly of medicine, is commonly regarded, however, as the special preserve of the experienced, and it is with some surprise that, on reflection, one is led to the conclusion that most great advances have been made by young men. We may take, almost at random, some of the greatest names in medicine, and test the truth of this remark. Virchow, for instance, began his series of investigations in pathology before he was twenty-five, and his theory of cellular pathology took definite shape not many years later. Morgagni, in Virchow's phrase "the father of modern pathology," sowed the seeds of that science when, as a medical student, a mere boy, he began keeping notes in parallel columns of the clinical history of the patient, and of his observations in the *post-mortem* room. Laennec began his methods of diagnosis when he was but little over twenty, although he allowed them to ripen for twelve years before he published them at thirty-five. Auenbrugger, his predecessor in examination of the chest, was little older when his great idea of percussion occurred to him. When Bright was thirty-five he taught the world nearly all it has ever known of inflammations of the kidney. The great men of the Dublin School of half a century ago did their most notable work before they were thirty. Corrigan, from the age of twenty-five to that of twenty-nine, studied the disease that ever since, by the suggestion of Trousseau, bears his name, in a hospital where there were only six medical beds. Stokes, at twenty-one, introduced the stethoscope from France to this country, and a few years later wrote his classic description of Cheyne-Stokes' respiration. To come to more modern times, Lister had not reached middle life when his epoch-making discoveries were made. Major Ronald Ross is, we are glad to say, still a young man, and it is several years since his researches on malaria placed our knowledge of that disease on a new plane. Finsen was still young when the hand of death stilled the energy of his intellect. We have instanced more than enough names to support the claim that youth and boldness hold their own against age and experience in the onward march of knowledge. Young men, therefore, should exercise their prerogative to the full, and should not, in attempting to lay foundations unnecessarily wide, dissipate that energy which properly directed should raise the walls of the house of knowledge.

A NEW BRITISH CONSTITUTION WITHOUT MEDICINE.

THE introduction of medicine as a factor into State business is an event of recent date, but so

quickly has it justified that introduction that one is frequently apt to fancy that the science of public health has taken as firm a grip of the British politician and Government official as its importance warrants. When public men come to medical dinners they always assure their hosts that the good medicine has done to the community by its preventive work is inestimable, and that they themselves will do all in their power to help forward the cause of public health. Happily, many of them are doing their best; but it is important for the profession to realise how little weight medical counsels in this country still have in State matters, and how many admirable publicists still regard hygiene as merely a hobby of the doctors. In Germany, France, and even America the requirements of the public health are thought worthy of more consideration than are afforded by their administration in a subordinate department in a minor Government department, but England remains content with its Local Government Board, and is satisfied that the head of its medical organisation shall receive a salary one-tenth that which the chief lawyer and the chief priest of the realm are paid, without enjoying any official status beyond that which he holds in virtue of his seniority in his department. This we are accustomed, if not reconciled, to, and when we look for change we are apt sometimes to turn to the reforming Radical to set matters on a more equable footing. Those who cherish this fond hope will, we fear, be somewhat disappointed if they read *Truth*. In his last number for 1904, Mr. Labouchere outlines a scheme for amendment of the British constitution on lines which he thinks every member of the rank and file of the Liberal party would agree with. Needless to say we have no concern, as an organ of general medical opinion, with the detail of the reforms there set out, beyond remarking that they are projected on the widest democratic principles. But what interests us chiefly is the constitution of the Senate, a body which is to take the place of the present House of Lords. This Senate is to embrace the collective, matured wisdom of the country in the persons of representatives of all the leading interests and professions. The Senate is to review the decisions of the House of Commons and to send back such legislation as it judges hasty or imperfect, besides exercising the usual functions of a deliberative body—the discussion of public questions and the passing of resolutions. The electors to the Senate are to be the members of the House of Commons, and they are to choose for the seats in the Upper Chamber three ex-judges, three financial experts, three manufacturers, three wholesale merchants, three retail traders, three admirals, three generals, three literary men, three architects or painters, twelve artisans—and no doctors! Without casting any aspersion on the other professions, we should have thought that the voice of such a man as Lord Lister—the only medical representative in the present House of Lords—might have been as

useful to the State as that of a painter or an artisan, when questions of public health—and there are few matters of State interest in which questions of public health are not involved—were under discussion. We venture to hope that the omission of medical men under Mr. Labouchere's scheme is an oversight, as the editor of *Truth* has a genuine respect for the proprieties of medical practice, even if he sometimes finds himself at variance with current medical views, and he is the implacable foe of the quack and impostor in every shape and form. But granting that it was intended to give a certain medical representation in the reformed Upper Chamber, it cannot be denied that there is a significance which should be missed in the failure to include them. This failure shows that the paramount claims of public health in regulating and modifying every scheme of solid amelioration or improvement are not yet recognised even by the most ardent reformers, and that there is a *soupcçon* of truth in the gibe which each political party hurls at the other that social welfare is regarded as secondary to other considerations. For ourselves, we make no complaint, beyond saying that it behoves medical men, in whatever station they are placed, to continue to work in season and out of season to keep questions of the physical well-being of the nation constantly to the front, for—apart from religious and moral considerations—there is no matter that affects happiness and prosperity to the same extent, and none that is more easily overlooked.

Notes on Current Topics.

A Loyal Gift to a Royal Fund.

THE humane modern spirit, in its finer phases, has perhaps its most noble expression in the great medical charities and in the great collecting agencies known as the "Hospital Funds." So far as London, the greatest city in the world, is concerned, Royalty has all along been closely identified with that movement. As everyone knows, the King's Hospital Fund for London was founded by King Edward, when Prince of Wales, to commemorate the Diamond Jubilee of Her late Majesty Queen Victoria. The King's wish has been to bring the fixed income of the Fund to £50,000 a year, but hitherto the total has been £14,000 short of that amount. Every inhabitant of the United Kingdom will rejoice that the greater part of the required sum has been most generously provided by Lord Mount Stephen, who has handed to the King bonds that yield an annual sum of £11,000. This munificent gift leaves £3,000 a year still to be provided, a gap that will doubtless be bridged over by some other friend of mankind. The King may be congratulated not only on having initiated so noble a scheme, but also in having loyal subjects willing and able to place its superstructure upon a sound and permanent foundation.

Stimulants in Literary Work.

THE medical profession is probably the most prolific of all callings in the production of books

and papers, and considering the amount of interesting material daily presented to its members, it is not wonderful that they should fly so frequently to print. There are few doctors who have not in their time written one or more professional papers, and a good many have contributed a considerable number to the columns of the professional weeklies and monthlies. All, except a chosen fraction, must, therefore, have experienced the difficulties of choosing the right word, selecting the exact construction, and conjuring up the most suitable metaphor with which to clothe and illustrate their meaning. They will, then, be interested in an article, in the *Cornhill*, entitled "Throes of Composition," in which the experiences of many eminent writers are related, and especially in that portion of it that refers to the aids to thought and expression adopted by well-known men. Thus Sheridan used port to bring out the ideas that lay a little too deeply imbedded in his brain; Wilkie Collins produced "The Woman in White" largely with the help of champagne; Fielding trusted to brandy and water; Charles Lamb sought the aid of wine or beer; whilst the great lexicographer depended on tea to carry him through his herculean task. But such artificial aids, excepting, perhaps, Dr. Johnson's, are not likely to find approval in this temperate age, and we think that most medical men will sympathise more with Milton, Kingsley, Buckle, and Tennyson in their partiality for tobacco. Cavillers at the weed may find their objections difficult to maintain in the face of the examples of the authors of "Paradise Lost" and "Maud," and we know of many treatises on more prosaic but none the less necessary subjects that would not have been produced except under the ægis of the same drug. Nor do we forget that Mr. Spurgeon used to defend himself by saying that he could smoke cigars to the glory of God.

A Graceful Concession—to Influenza.

THE key to the prevention of disease lies in the study of causes, and foremost among the methods by which causes should be reviewed is the statistical one. It is also the most technical one, and for this reason the one that is most likely to be eschewed by the female mind in search of information. Swedish ladies, however, may be more mathematically-minded than their sisters, for the ladies of Haparanda have been making researches in etiological statistics that have brought to light hitherto unsuspected facts. The chief of these is that during cold weather men suffer three times more often than women from influenza, neuralgia, colds, and similar maladies. The gentleness of these Haparanda ladies has been much touched by this discovery, and extending their inquiries, they have come to the conclusion that the root of this unhappy state of things lies in the demand that politeness makes on the sterner sex to expose their heads to sudden changes of temperature each time they meet a female acquaintance. They have therefore graciously let it be

known that they will not expect their men friends to take off their hats in the streets during the cold weather, but that they will consider the usages of good breeding satisfied if the military salute be given. This is very nice and considerate of the ladies; we only hope the gentlemen will not forget to revert to the more established form of salute when the weather grows warmer. But the fears of Haparanda need not flutter the feminine dove-cotes west of the North Sea. The race of men, however, must indeed be degenerate that needs fear a bare head in any British weather. We prefer to believe that the national robustness is better testified to by the movement in favour of no hats at all, which has lately found adherents and converts among both men and women.

Sight-testing Again.

WE have commented already on the attempts that are being made by various bodies of unqualified persons to procure for themselves certain privileges as regards sight-testing. Chemists, optical instrument dealers, and others, wishing to adopt sight-testing as a "side-line," obtain certificates of proficiency from some body or other, such as the British Optical Association or the Spectacle-makers' Company, and thereupon pose to the public as experts. An interesting development of this movement is the proposal of the British Optical Association to promote a Bill in Parliament "to define and regulate the practice of optology." The projected Bill would enact that a register of "optologists" should be established, on which every person practising "optology," medical men excepted, must have his name enrolled. Admission to such register would be gained either by proof that one has been engaged for a certain length of time in the practice of sight-testing, or by possession of some such certificate as we have mentioned above. It is hardly necessary to point out to medical men that such claims to registration are valueless as marks of knowledge, and that, as far as the medical profession is concerned, we can countenance no attempt to endow any body of tradesmen or mechanics with the privilege of pursuing a branch of medical practice. The operation of testing the sight is part of the general examination of the eye, and requires for its performance a knowledge of physiology and anatomy, of the possession of which there is no guarantee outside the medical profession. The proposal of the British Optical Association need hardly, however, be taken seriously, for Parliament cannot for a moment consider such an audacious demand.

Flies and Tuberculosis.

A VALUABLE and original contribution to the etiology of tuberculosis is contained in the *Boston Medical and Surgical Journal* for December 15th, 1904. Lord, writing in that journal, details the results of some experiments he has been making with regard to the rôle played by flies in the dissemination of tubercle bacilli, and his work,

having been very carefully performed, throws a significant light on the doings of this oft-suspected insect. Lord had often noticed that flies showed a special predilection for feeding on sputum, even when other food was available, and he therefore set about and deliberately allowed them to partake of tuberculous expectoration, with a view to examining their droppings afterwards. He found that not only did the tubercle bacilli pass through the alimentary canal in a comparatively short time, but that when recovered from the excreta some of them were able to live for fifteen days afterwards, thus showing that they had lost none of their vitality. Indeed, they would seem to have increased, for the excreta of flies fed on sputum exhibiting ten tubercle bacilli per microscopical field were found to contain no less than a hundred and fifty per microscopical field. Paraffin sections were made of the flies, and tubercle bacilli were demonstrated in the actual intestinal contents, though the organs themselves seemed free. A noticeable feature about the bacilli recovered from the droppings was that these were larger than those in the sputum, and in some instances showed a tendency towards branching. Lord dwells upon the obvious moral to which his experiments point, and with his experience before one's eyes that moral cannot be too closely taken to heart. If we cannot have "anti-fly" campaigns in this country, we can at least take every precaution to guard our food from contamination by flies, but even these leave loop-holes for infection that it is not very comfortable to contemplate.

Fatigue Antitoxin.

INTEREST in the subject of fatigue will probably continue as long as people know what it means to feel tired, and a good deal of interest has been aroused in lay minds by Sir William Gowers' erudite article on "Fatigue" in the *Quarterly* for October. The latest views on the subject are there set out, and it is particularly noticeable that physical and mental exhaustion are shown to be intimately related one with another. Fatigue is due primarily to the manufacture in the tissues, and especially in the muscles, of toxic waste products, and it occurred to Weichardt (a) that if this were so, it ought to be possible to obtain an antitoxin capable of neutralising this toxin, and of enabling the exhausted tissues to renew their youth like the eagle. He therefore set to work attempting to extract from the muscles of fatigued animals the toxin that had been manufactured in them, and this he was able eventually to obtain by dialysis of the extractives. Very small quantities of the body thus obtained will, when injected into animals such as rats, mice, and guinea-pigs, give rise to all the symptoms of fatigue, and larger quantities will produce death. These results were verified by control experiments made on similar animals with injections from the dialysable muscle extracts of unfatigued animals, the injected

(a) *Monch. med. Woch.*, November 29th, 1904.

animals in these cases showing no particular disturbance. The introduction of this dialysable toxin into a horse's circulation gave rise to the formation of an anti-body, which was able to neutralise the toxin both within the tissues and *in vitro*. The antitoxin so obtained was found to be a stable body of great potency, capable of neutralising ten times its weight of toxin. Weichardt now administers the antitoxin to man by the mouth, and claims that the subject is able to accomplish more work without fatigue than before, and that if taken continuously it greatly increases the power of work and the enjoyment of it. Most schoolmasters, we fancy, would be glad to have an occasional dose of this antitoxin by them; indeed, there are few walks of life in which it ought not to prove useful. The gentlemen who are "born tired" will now be without excuse.

Paget's Disease of the Nipple.

THE pathology of Paget's disease of the nipple has been the subject of much discussion since the description of the condition by Sir James Paget in 1874. The important clinical points are the intractable nature of the complaint and its liability to be followed by malignant disease. Mr. Mayo Robson, in his recent Bradshaw Lecture, referring to pre-cancerous conditions of the breast, advised excision of the nipple if eczema of that structure did not speedily yield to treatment, and he has met with some criticism for so doing. That eczema of the nipple is followed by cancer in some instances is undoubted, but opinion would seem to be still a good deal divided as to the frequency of the sequence. It is interesting in this context to notice that Jacobäus, in a recent paper (a), concludes, as the result of his observations, that Paget's disease is cancerous in nature from its outset, and always starts in the glandular epithelium of the galactophorous ducts. The slow progress of the malady he attributes to the resistance to extension offered by the muscular and fibrous tissues, so that if the growth is deeply seated it more readily progresses along the ducts than into the breast substance. The so-called Paget's cells he regards as detached cancer cells. Jacobäus' view is hard to reconcile with the fact that nipple-eczema sometimes is cured without giving rise to further trouble, but it lends weight to the advice that the conditions should be seriously regarded, and submitted to surgical treatment without undue delay.

Japanese Losses in the War.

A RECENT number of a Japanese contemporary (b) gives interesting tables regarding the losses undergone by the Japanese navy during the present war. From February 9th, when the first losses took place at Port Arthur, up to October 9th, the total number of killed and wounded of the Imperial Navy was 2,321, of which 1,022, or nearly one-half were killed. The greatest loss on any one day was that at Port Arthur on May 11th, when

a total loss of 921 took place, 494 being killed. Among these were Fleet-Surgeon Seki and Surgeons Uyemiya and Kusaka, who went down with the ships *Hatsuse* and *Yoshino*. Again, in the engagement in the Yellow Sea on August 10th, 65 men were killed and 161 wounded. In addition to the medical officers we have mentioned only three other surgeons have been lost during the war. Six were wounded, but are now quite recovered and again at service. The hygiene on the Japanese ships must be excellent, for only six surgeons and thirteen medical attendants were attacked by infectious disease—dysentery or typhoid fever. We are glad to state in the quaint phrase of our contemporary "none of them did die of the diseases."

The International Congress of Medicine.

WE have received the fourth number of the "Official Journal of the International Congress of Medicine," which is to meet at Lisbon on April 19th, 1906. From the subjects chosen, the number of papers already promised, and the names attached to them, it is evident that the meeting will be one of great interest. We understand that all the papers will be printed in advance, so that the confusion of tongues, of which complaint has been made in the past, will be to some extent obviated. Among the English medical men who have promised to take part are Mr. D'Arcy Power, who is to discuss "The Causes, Sequelæ, and Surgical Treatment of Ulcers of the Duodenum"; Mr. Treacher Collins; Dr. Samuel Osborn, of Datchet, who is to make a communication on "An Armoured Motor Ambulance as a First-Aid Dressing Station"; Dr. Stanley Atkinson; and Dr. F. W. Mott, who is to read a paper on the "Histology of Sleeping Sickness." The Journal contains a list of the various national committees which have been formed to prepare the work of the Congress. The British Committee is a representative one, Dr. Pavy being President. We notice that the University of London is to send to the Congress a special delegation consisting of Sir Thomas Barlow and Professor Waller.

Unqualified Chemists.

OUR readers are aware that by a misuse of the Companies Act unqualified persons have been able to evade the legal responsibilities of the dental profession, and by enrolling themselves as limited liability companies have been permitted to practise dentistry without let or hindrance. Similarly, through a flaw in the Pharmacy Act of 1868, adroit persons, without the necessity of possessing any knowledge of chemistry or pharmacy, have, by forming companies, made themselves free to carry on business as chemists. Such traders are bound by none of the restrictions imposed by law on registered chemists and druggists, and are free from certain conditions, such as those with regard to the storage of poisons, which are considered necessary in the public interest. Some of these businesses have been attracting much attention to

(a) Virchow's *Archives*, Vol. clxxviii. No. 1

(b) *The Sei-i-Kwai Med. Journ.*, October 31st, 1901.

themselves recently by their extravagant advertisements, in which they impudently contrast their methods with those of the "ordinary retail chemists," as the legitimate trade is termed. It is stated by one of these firms that their drugs are purer, of higher quality, and cheaper than those sold by other chemists, and that this superiority is possible because of the large trade done by them. Every trader speaks well of his own goods and there is no need to take these claims more seriously than other trade announcements. At the same time, medical men are well aware that "cheapness" in itself is not necessarily a point of merit in drugs. From the point of view of the public, moreover, it is of much more importance that the sale of drugs and the dispensing of prescriptions should be in the hands of skilled, careful, and responsible persons, than that drugs should be cheap or even of high quality, important as this may be. Medical men will do well then to see that their prescriptions are made up by qualified chemists, and to warn their patients against being misled by specious promises to trust incompetent persons.

The Fatal Accident at the London Coliseum.

THE death last week of a jockey, riding in the realistic horse-race at the newly-erected Coliseum in London, forces the subject of dangerous performances once again before the public conscience. For the benefit of provincial readers it may be explained that real jockeys on real racers ride an imitation Derby on a rapidly revolving platform. It is needless to point out that the planting of a horse's foot on the non-revolving centre of the platform would lead to instantaneous somersaults. The fatal accident a few days ago resulted from some such mishap. The whole performance is so absolutely dangerous to life and limb that in our opinion it should be stopped at once. The London County Council should assert their right of control and put an end to these disgraceful exhibitions. In the case of the Coliseum they can interfere, if only on the ground of danger to the audience. Should one of the racers fall on the revolving platform, the deadly havoc that might instantly be wrought is terrible to contemplate. The fall of a leading horse would rake the field as if a volley of shrapnel were fired into the ranks of the racers. The management of the Coliseum, having now had due warning, will have to be held responsible for any subsequent accident in this part of their performance. Prevention, however, is better than cure in horse-racing as well as in other mundane matters.

The Proposed Sterilisation of the Unfit.

IN another column will be found a communication from Dr. R. R. Rentoul, as to his scheme for the prevention of degenerate offspring. Whatever the future may have in store, it seems tolerably clear that the philosophy of modern civilisation is not yet ripe enough to carry any such proposal into practice. The summary methods of the Spartans

long ago weeded out degenerate children as fast as they were produced. Dr. Rentoul would go deeper and prevent the begetting of children by certain groups of degenerate parents, such as idiots, lunatics, and criminals. His radical method is to sterilise parents of both sexes who may be found by the State unworthy to have offspring. One great difficulty is to determine the parental degenerate, and the next to appoint the State executioner. Some day mankind will doubtless attain some sort of intellectual and moral millennium in which the sterilisation of degenerate parents will become an established practice. Meanwhile it is evident that the yearly production of an enormous number of physical and mental degenerates inflicts a gross injustice upon the unfit offspring, and an intolerable burden upon the community. The release of so-called "cured" patients from lunatic asylums for recurring periods, during which they go home and beget more children, is a scandal and a reproach to an otherwise enlightened and progressive system. Even "cure" may be purchased at too dear a price.

The Hon. Sydney Holland and the London Hospital.

WE have published several letters from Mr. Sydney Holland with regard to the money advanced by the London Hospital to its attached medical school for the purpose of purchasing a sports ground for the students. Mr. Holland's explanation certainly places the affair in an aspect different from that presented recently at the Sunday Fund meeting. We are pleased to accept his proposition that the money advanced by the hospital is covered by ample security and by a fair interest paid by the school as rent. It is reassuring to learn, moreover, that the accounts of the medical school are open to the public. It has often been stated in these columns that we have implicit trust in the good faith and honour of Mr. Sydney Holland. As a public man, however, he must expect criticism. We have unbounded admiration, moreover, for that splendid charity, the London Hospital, over which he presides. At the same time, these feelings will not prevent our offering criticism when it seems to be needed. We still think it a pity that a better defence could not be found in answer to a public question as to the alleged diversion of charitable funds than to cast aspersions upon the questioner. Mr. Holland's case is a strong one, in our opinion, and capable of reasoned defence of a sufficiently powerful description. Meanwhile hospitals and hospital chairmen must learn to formulate their administrative policy in such a way that everything may be clear as daylight to the man in the street.

PERSONAL.

It has been announced that Surgeon-General W. J. Fawcett, C.B., will shortly be ordered to go from Dublin to London to take up the duties of Deputy-Director-General of the Medical Service under the new Army scheme, and will be relieved in Ireland by Surgeon-General Donovan, C.B.

THE KING AND QUEEN last week visited the Devonshire Hospital at Buxton. His Majesty promised Dr. Turner, the Senior Medical Officer, a new glass operating table for the use of the hospital.

HER MAJESTY THE QUEEN has sent ten brace of pheasants to the Royal Waterloo Hospital for Children and Women, of which Her Majesty is one of the oldest patronesses.

At the meeting held on December 27th, 1904, of the Paris Academy of Medicine, after keen competition M. Chamberland was elected as "*associé libre*" of the Academy of Medicine on the third ballot by 53 votes in room of the late lamented M. Duclaux.

DR. W. ST. C. SYMMERS, of Cairo, has been appointed Musgrave Professor of Pathology at Queen's College, Belfast.

LORD MOUNT STEPHEN has presented bonds to the value of £200,000, yielding an annual income of £11,000, to King Edward's Metropolitan Hospital Fund.

SIR JOSEPH FAYRER, M.D., F.R.C.P., Bart., K.C.S.I., now residing in Falmouth, has recently celebrated his 80th birthday.

THE new headquarters of the Manchester Companies of the Army Medical Corps were opened on the 7th inst. by Major-General M'Kinnon, Director-General of Auxiliary Forces.

MESSRS. ALLEN AND SON, solicitors, Carlisle Street, Soho Square, W., have made the first three endowments of the Jessie Alice Palmer Charitable Fund, under the bequest of £1,000 each in memory of Jessie Alice Palmer. They are as follows:—£1,000 to Westminster Hospital, in recognition of the services to science of Dr. William Murrell, F.R.C.P.; £1,000 to Queen Charlotte's Hospital, in recognition of the services to science of Dr. W. S. A. Griffith, F.R.C.P.; and £1,000 to the British Home for Incurables.

Special Correspondence.

[FROM OUR OWN CORRESPONDENTS.]

EDINBURGH.

EDINBURGH ROYAL INFIRMARY.—The annual report of this institution, presented to the Court of Contributors at the statutory meeting of January 2nd, contains, in addition to the usual financial and statistical statement, paragraphs dealing with the re-organisation of the surgical out-patient department (which has been the subject of considerable criticism in the Press within the past year, on account of alleged delay in dealing with casualties) and with the age limit question. In the new scheme for the treatment of surgical out-patients, the feature to which the managers attach most importance is the arrangement whereby there shall be a continuous supervision of the department by a responsible officer. This is to be obtained by putting it under the sole charge of one of the assistant surgeons, in rotation, for four months at a time, during which period he will be freed from all other duties and be present in the department daily at 11 a.m. To assist him a special staff is to be provided, consisting of three resident surgeons, dressers, nurses, a registrar clerk, and two day and two night porters. One house surgeon will be present in the department during each hour of the day or night; and two during the ordinary out-patient hours. To allow of the proper working of the scheme the present out-patient rooms will require to be reconstructed and a small operating theatre built. After recapitulating the various phases through which the age limit question has passed since last report (these have from time to time been announced in this column and need not be

repeated), the report goes on to say that, although in the decision of the Court of Contributors, which the managers loyally accept, no mention was made of any exceptions to the rule that members of the staff shall retire at the age of sixty-four, the managers assume that it was the intention of the Contributors that the rule should not apply to members of the full staff serving their second or third terms of five years. The report was, as usual, remitted to a Committee of Contributors for report to an adjourned meeting, and the proceedings on January 2nd were largely formal. The Lord Provost's observations on the new rules were met with applause, and it is to be hoped that the view expressed will ultimately be agreed upon. He said he took it for granted that the age limit would not apply to the present professors; he understood that the promoters of the new rule took the same view. It would be most unfair to apply the rule to gentlemen who had been appointed under certain conditions, and if this were agreed to, harmonious working would be secured and friction avoided. Nor should the rule apply to members of the ordinary staff, who were serving their second or third term. It is generally felt that if the Contributors now endorse the managers' action, they will alike safeguard vested interests and promote a most desirable reform.

MEDICAL AND DENTAL DEFENCE UNION OF SCOTLAND.—From the details given in the second annual report of this Union, which has just been issued, it is quite evident that a useful organisation has been placed at the disposal of members of the profession. During the year the membership has increased to 615, 149 more than the 1902-3. From the examples given in the Report of the work done by the Union, it is gratifying to learn that in comparatively few cases was recourse to litigation found necessary, and that the Union is evidently being largely taken advantage of by members requiring advice in delicate matters, ethical and otherwise, affecting their professional interests. On account of the differences between Scotch law and that of England such a society as this was really a necessity, and the gratifying increase in its membership during the year is a proof of its usefulness.

GLASGOW.

PRELIMINARY EXAMINATIONS AT SCOTTISH UNIVERSITIES.—The results of the preliminary examinations at the four Scottish Universities—St. Andrew's, Glasgow, Edinburgh, and Aberdeen, for the year 1904, have just been issued, and show a stringency of examination which indicates that the standard has been raised considerably. The influx of students to the Universities, of those anxious to avail themselves of the Carnegie Fund, is in all probability responsible for the large number of failures at the various examinations. In future we understand the Carnegie students will have to pass the examination in Arts. The numbers entering for several subjects seem to be very considerably larger at Glasgow than at Edinburgh University, the actual numbers being: Glasgow 1,327, Edinburgh 752; failed at Glasgow 558, passed 449; failed at Edinburgh 329, passed 272. These figures do not represent the number of students, of course, but the number of entrances for the different subjects, some students entering for two, three, or four subjects. It was thought that at the last medical preliminary examination in Glasgow University in September the marking in some of the subjects was unduly severe, and therefore the number of failures unusually large.

GLASGOW SOUTHERN DIVISION OF THE BRITISH MEDICAL ASSOCIATION.—On Thursday evening, the 5th inst., a general meeting of the members of the above Division was held in the Library of the Medical Club, 22 Carlton Place; the Vice-Chairman, Dr. Alex. Miller, occupied the chair in the unavoidable absence of the Chairman, Dr. James Hamilton. Dr. C. E. Robertson, the representative of the Division at Oxford, gave an interesting account of his stewardship there, and of the work done by the collective

body of Representatives at their meetings held at Oxford last year. The subject of Contract Medical Practice was then discussed, and considerable progress was made, but it was agreed to delay the further discussion of this important subject for a fortnight. The Division has arranged to hold fortnightly meetings on account of the large amount of work to be overtaken during the next few months. This is one of the most active of the various Divisions. The profession in the City has been divided into four divisions—Northern, Southern, Eastern, and Central. Hitherto the difficulty has been to get the members to attend the meetings. The attendances have been small at the various divisional meetings in the past, and in view of that it has been suggested that, instead of having so many separate meetings, the experiment might be tried of holding conjoint meetings occasionally. This branch of the Association work has not got beyond the experimental stage; and now the members have the opportunity given them of having existing grievances redressed, it is quite remarkable the amount of apathy that prevails with reference to the work sent in from the Council of the Association in London for the consideration of the different Divisions. The meagre attendance at meetings is not confined to Glasgow nor to Scotland, as we read in the supplement to the *British Medical Journal*, of Saturday, January 7th, 1905, that at a meeting of the Birmingham Branch, Central Division, when the important and clamant subject of Contract Medical Practice was under consideration, that there were 14 members present, and 278 absent! If this lack of interest on the part of members of Divisions in business which closely concerns them individually and collectively should unfortunately continue it will have to be seriously considered whether the original state of matters should not be reverted to. It ought to be remembered by members of Divisions that the expenses incurred in carrying on the work are considerable. The Association yearly allowance of 4s. per member is a fairly generous one, and it is to be hoped that the members of Divisions will begin to take a greater interest in the abundant work which lies to hand, and so justify the large expenditure involved, and the existence of the Divisions as at present constituted.

INTERESTING MEDICO-LEGAL CASE.—IS INSANITY A DISEASE?—A case of considerable interest to the medical profession has just been decided by Sheriff Principal Sir John Cheyne, in an appeal against a judgment of Sheriff Substitute Lyall of Paisley. A member of the Irish National Foresters became incapacitated for work from bodily sickness, which in course of time culminated in insanity, and this required his removal to an asylum, where he was confined for two or three years. His friends raised an action against the Friendly Society for aliment, and this action the Society defended on the plea that the man was not suffering from bodily disease, but from insanity, and that the rules of the Society only allowed of aliment being given in cases of bodily sickness. After the examination of many witnesses, including a number of medical men, the Sheriff Principal sustained the judgment of the Sheriff Substitute in favour of the defenders, the Friendly Society, and went on to say that he concurred with the Sheriff Substitute in holding it to be a fair result of the medical evidence that pursuer's inability to work was not due to bodily sickness in the ordinary and natural sense of that term, but was due to insanity. He had come to this decision with a good deal of difficulty, as the rule of the Society applying to bodily sickness was rather awkwardly expressed. He had to concur with the Sheriff Substitute in holding the Friendly Society in the right on the merits of the case. He hoped, however, the Society would see its way to render the family more assistance from their Benevolent Fund. We refrain from commenting on this interesting case as we understand that it has been appealed to the Court of Session, where it will probably be discussed at no distant date.

BELFAST.

THE CHAIR OF PATHOLOGY IN QUEEN'S COLLEGE—As announced in these columns last week, Dr Simmers, of Cairo, has been appointed to this chair, in succession to Professor Lorrain Smith. Some disappointment has naturally been felt, especially by the younger medical men, at the non-success of the local candidate, but it is generally recognised that Dr. Simmers' claims were very strong, his experience being so wide. His record in Cairo has established his reputation as one of the foremost of the younger pathologists, and he will find in Belfast a flourishing school with ample opportunities for work, and abundant post-graduate assistance.

THE BELFAST CORPORATION AND PUBLIC HEALTH.—At its monthly meeting held last week, the Corporation devoted several hours to discussing the rather serious state of the health of the city, and attention is being drawn in the daily Press to some of our more glaring faults. As the *Northern Whig* very sensibly remarked, "Modern sanitary science has rendered it an impious act for man to lay upon Providence the blame for his own sins of omission and commission in the matter of health." During last month no fewer than 222 cases of zymotic disease were reported, including 58 of scarlet fever, 32 of typhoid, 21 of smallpox, and 17 of diphtheria. There were 79 deaths from zymotic disease, 89 from phthisis, and a death rate of 22 per thousand. Perhaps the most pressing matter is the smallpox outbreak, which is again assuming unpleasantly large proportions. There were 29 cases during the month, and 37 cases are now under treatment at Purdysburn, all the beds in the hospital being full. At the intercepting hospital 50 contact cases are under observation. Meantime the Belfast Board of Guardians can find no better occupation than discussing the action of a dispensary doctor who, following the instructions he received from the public health authorities, vaccinated the children in a school in an infected district without waiting to consult with their parents. The sapient Guardians, after a prolonged discussion, passed a resolution condemning his action, which resolution, however, is not likely to affect that gentleman's happiness. Smallpox is not by any means the only source of danger to the public health at the present time. There are no effective guarantees of the purity of the milk sold in the city, and overcrowding is rife in certain quarters. Altogether there is a fine opportunity for an energetic reformer, but as yet none has appeared.

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

PROPOSED STERILISATION OF CERTAIN DEGENERATES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your issue of the 28th, a communication, well worth reading, appears from Dr. W. McDermott. But Dr. McDermott says what I think he does not mean, when he states that he would not care to decide who shall and who shall not be sterilised. Now our last census showed that there were in the United Kingdom, on one day, 60,721 idiots, imbeciles, and feeble-minded; and of this number, 18,900 were married. Does any doctor contend that these are a good or a bad stock to breed from? Does any doctor wish to agree that his daughter may marry one of these degenerates? As these poor wrecks of humanity will not refrain from procreation, the only plan is to sterilise them. Some contend that life-long incarceration will meet the difficulty. It will not. The cost of life-long incarceration of all degenerates likely to beget degenerate offspring would amount to about £80,000,000 per annum, and surely the taxpayer is already overburdened? Take again the habitual criminal and habitual inebriate. Can these people be expected to beget a healthy offspring? They cannot, and therefore the

only plan is to sterilise them. Take again the sexua pervers—sodomists. These scum of humanity suffer from a mono-mania, and nothing more. I have heard it stated that there are some 900 of these in prisons. Now if these persons had their spermatic cords divided and ligatured, they could be made to work, and would be freed of doing harm. We have no right to give those demented persons fifteen to twenty-five years. The modern humanitarian has gone mad in this question, and with the result that we are interfering with the liberty of a goodly number of persons. I give these cases to show that Dr. McDermott and others need not have any difficulty in deciding upon these coarser types of degeneration. When we come to the finer forms, great care will be required, and to meet all cases I have proposed that no one shall be sterilised without the written consent of the Lunacy Commissioners; that only a few medicals shall be licensed to operate; that any person sterilising any person for the purpose of checking degeneration without the consent of the Commissioners shall be given fifteen years' penal servitude; that a yearly report shall be laid before both Houses of Parliament, and that if a sterilised person marry a non-sterilised person without first notifying this fact to the non-sterilised, such person shall be imprisoned for fifteen years, and further, that any person using a sterilised person for immoral purposes shall be similarly punished. What further protection can be required?

It has been suggested by me that we should obtain the consent of Parliament to sanction this operation of sterilisation. It will be difficult to obtain such sanction because it is well understood that every surgical operation is legally an assault, and that therefore the consent of patients or guardian is necessary. No law exists empowering a medical to kill the child in the womb so as to save the life of the mother, and no such proposed law is likely to be adopted. I have been told that the most supreme of all personal rights is the right to do what one likes with one's own body. If therefore, a man is discharged from an asylum as recovered (?) and lives with his wife again, would it not be best for the coming race were the man sterilised? And the same with all women who have had puerperal insanity. I fully recognise that the average man—including the average medical—does not consider it a crime to stamp a child with some mental degeneracy, or physical deterioration. The infant is of no account. It cannot defend itself. It cannot command so many political votes, and therefore the average Christian practically says, "kick it again; it has got no friends." This feature of non-protection of infant life from the disease of the parents is one of the most repulsive and damning of modern Christian life and thought. We fine a person £5 for exposing others to an infectious disease which he is suffering from, while the parent who gives a child syphilis, or some inherited degeneracy, is allowed to go free—allowed to leave the Christian court "with no stain upon his (or her) character"—as the usual jargon goes.

Now I think it full time that we medicals should establish a religion of Health, and make it a crime when people beget tainted offspring. The insane cannot be blamed, as we label them "irresponsible." Therefore we should sterilise them. If we do not, what will happen? At present, the more healthy and well-to-do are refusing absolutely to have a fair number of children, while the future race is being left to the degenerates, the poor, and the invalids. What stock must we get from this kind of breeding? Only a larger and larger number of degenerates. As illustrating this I have given two cases. In one, five unmarried weak-minded females had been confined of fifteen children in one workhouse in Yorkshire. In the other, a half imbecile female had left the asylum to marry! She had been confined of no less than nine idiot children. Do medical men mean to say they are doing their duty to the public health and public safety when they allow such things to go on without loudly protesting?

Mr. G. R. Sims has lately given the life history of two families of degenerates. They are as follows:—

The first. Wife, 37; father, 35; wife's mother for 26 years in asylum. Children—(1) Tom, constantly ailing; (2) James, all right; (3) William, delicate, always ill; (4) dead, inflammation of brain; (5) dead, inflammation of brain; (6) dead, inflammation of brain; (7) Jane, imbecile; (8) Herbert, infantile paralysis; (9) Annie, very delicate; (10) Mabel, no use of legs; (11) Emily, very delicate.

Second case.—Wife, 67, invalid. Husband, died of consumption. 11 children, 8 living. (1) girl, deaf and dumb; (2) girl, dumb; (3) boy, deaf and dumb; (4) boy, cripple; (5) girl, married.

Daughter's family.—(1) wife, insane; (2) husband, almost blind; (3) boy, normal; (4) boy, no injury; (5) girl, no use of limbs; 5 children have died.

I would like to suggest that the columns of THE MEDICAL PRESS AND CIRCULAR be at the disposal of any medical who will take the trouble to work out even one case such as the above. In this way dependable material will be at hand, more especially for the use of those who feel that heredity has more to do with such cases than environment.

I am, sir, yours truly,

ROBERT R. RENTOUL.

Liverpool, January 2nd, 1905.

THE LONDON HOSPITAL SPORTS GROUND.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The matter is perhaps hardly worth more discussion. I have told you twice that the purchase of the cricket ground was not money "spent" as you put it, but invested, and well invested by the Hospital at good, well-secured interest. I cannot see how you can possibly differentiate between the purchase of this freehold and the purchase of freehold lands in London, in which a large portion of our London Hospital money is invested, or, for a matter of that, between this investment and an investment in Consols. I think it most unfair to write of this investment as money "spent," i.e., as money that is gone and bears no interest. And I should have hoped that when your mistake was pointed out to you courteously, you would have expressed some regret. I have confused no issues. You wrote nothing about the purchase of "sites for medical schools"—our whole correspondence has been on the question of the investment of £6,000 by the Hospital in freehold cricket ground at a secured rental on lease of £240 a year.

As to the new point raised, I am blamed (of course) by you because I defended the action of the Committee of the London Hospital in refusing to accept £1 from Mr. Coleridge. We refused it because we had a right to assume that it was not given with any idea of helping the hospital, but with some sinister motive. What motive actuated the proffered sovereign we could not tell. But Mr. Coleridge is consistent. He is an anti-vivisectionist, and unlike so many anti-vivisectionists, he does not kill or pursue animals for pleasure, nor does he profit by the vivisection (without anaesthetics) of male animals to fit them for food, as he is a vegetarian. One admires him for this. Now he has preached to everyone, "Don't subscribe to the London," "Don't subscribe to Guy's" and other hospitals to which a medical school is attached where vivisection is licensed. Therefore, if he practised what he preached he would not subscribe, and we were justified in thinking that the sovereign was sent for no good purpose. I believe some other hospitals also refused his £1. I am not aware that I have ever "taunted" him, as he writes to you, "for not being a subscriber"; but really my correspondence with Mr. Coleridge has been of so breezy a nature that I can believe anything of either of us. Still, I would like to see that "taunt."

I am, Sir, yours truly,

SYDNEY HOLLAND.

Kneesworth Hall, Royston, Herts.

January 5th, 1905.

HOSPITAL FUNDS AND SMALL HOSPITALS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—“Outsider’s” letter does not go far towards a solution of the problem. He displays confusion of thought with regard to the main issues, and this needs no demonstration to any intelligent reader; but as you have printed his letter, I assume you wish me to reply. He asks me whether I “know of any physician or surgeon attached to any London hospital, general or special, who does not expect to be helped on in the world through his connection with the hospital?” I have never put this query to any of my friends; but I doubt not they would answer it in the negative. At the same time, I am sure members of the staffs of general hospitals can all point to careers of distinction won by hard work from student days onwards, through minor appointments to their present positions. The positions on the staffs of our great hospitals are the reward of professional merit and of high personal character—this latter qualification often rightly determining the result of an election. That the staffs of our great hospitals shall be really men of distinction, generally and specially, is guaranteed by an admirable system of selection, albeit some flaws in it may be possibly discoverable. Our great hospitals do not even remotely exist for the purpose of enabling practitioners to achieve worldly success. Their prime aims are the relief of the suffering poor, medical education and scientific observation and research; and they seek out and gain the assistance of the most able men available in promotion of these aims. The profession and the public quite rightly look upon our great hospital physicians and surgeons as eminent in virtue of their positions; and if some worldly success follow, it is mostly far from an adequate return for the honest toil involved in its acquisition. On the other hand, the founders of most of the older special hospitals, and the managers of some of the newer ones have been influenced by the desire, first of all, to provide a means of personal advertisement. “Outsider” thinks repetition is not argument; but perhaps he will tell us what justification to a medical reader is possible for the establishment of hospitals for deformities, or skin, or for the rectum, or ears, or eyes, or throats, or stone, or teeth, or hearts. To justify them to the public is, however, quite easy. It is only necessary to insist that no hospital for such and such a disease exists, and dishonestly to ignore the fact that the disease in question is received and treated in the out and in departments of all general hospitals. Indiscriminate charity is one of the evils of the day; the benevolent are always eager to open their purse-strings in response to a plausible cry. The plausible cry or cunning false pretence of the astute special hospital promoter has thus rarely failed when long enough persisted in.

A central London hospital board, with full powers, would certainly proceed to close all unnecessary special hospitals. The patients would be gradually transferred to the general hospitals, where the accommodation would be extended when needed, and additional specialists would be elected to carry on the extra work. The specialists would all present the best available guarantees of their claims to their titles and of their claims to the respect of their profession. Members of the staffs of existing special hospitals who could show valid claim to the distinction could be given preference in the new appointments. The mass of new clinical material would be made the best use of both in education and in science. A good deal of the sham specialism of the day would be at the same time done away with, and the public might be taught gradually to perceive that a great many maladies now classed by pseudo-specialism as special diseases, are merely symptoms of constitutional states which cannot be treated properly, or even understood, as local or special diseases. With regard to waste of funds, your leader to-day (January 4th) suggests the thought that if the property and the subscribed income of only one of the several orthopedic hospitals could be divided

among the general hospitals of London, a department in every one of them for the treatment of deformities might be opened adequately equipped for all possible demands upon it, and put, by endowment, beyond the reach of want for many a long year. The funds of the remaining useless and sham special hospitals would together do much more in similar directions. The special hospital system is fundamentally wrong, wasteful, and harmful, even when honestly conducted; when used for personal ends it inflicts deadly injury upon the profession, the sick poor, and the cause of true charity, as well as upon the progress of medical science.

I am, Sir, yours truly,

HENRY SEWILL.

January 4th, 1905.

Literature.

CAUSES OF CANCER. (a)

THE perennial attractiveness of the subject of diseases of the breast to all surgical practitioners and pathologists is one which, probably, can only terminate with the healing art itself. Special interest must always attach to the disorders of the organ which naturally functions as the source of man’s earliest nutrition—and did so before the days of the bottle-feeding and patent foods, which pretty surely furnish a trustworthy factor in the “devolution” of the race of which we have been hearing so much of recent months. And the subject of cancer, in general, is now of greater relative magnitude than at any previous period, at least of modern times; for bacteriologists assure us that they have ascertained the *causa causans* of every one of the other great plagues which have in turn tortured and decimated the human race, and has still survived into the twentieth century. And as they are confident, too, that they hold in their hands all the necessary weapons for the destruction of such enemies, the completion of the processes of sapping and mining requires only time—with the continuous services, of course, of an efficient commissariat. But the case of cancer stands alone. No microscopic decision has yet been arrived at regarding the true nature of this deadly and loathsome enemy of human life—a fact which makes its deadliness all the more weird and gruesome. Dr. Doyen’s claim cannot yet, of course, be regarded as finally settled.

The prominence of the place occupied by cancer of the breast in the minds of the healers of all ages is well shown by the allusions in the writings of the early “Fathers” of medicine which have descended to us. All give it a prominent place; all seem to regard this position of the disease as the most typical—with regard to developments and results; and the physical appearance of the “cancer” of this organ appears to have inspired the name by which the disease is now universally known. We are told by Galen—as Englished by James (of “powder” celebrity)—that: “Cancerous tumours are generated in all parts of the Body, but mostly in the women whose natural purgations are ceased, which, while under due regulation, preserve a woman in health. All præternatural tumours, therefore, of this kind, are generated of a superfluity of black bile, of which we have spoken in our treatise of Natural Powers, where we showed, that this Humour was generated in the liver, in sanguification, after the manner of Lees in Wine; but was purged by the spleen; whose natural aliment it was. . . . We have often observed in the breasts of women, a tumour very much resembling the animal called a Crab (*harkinos*); for as this creature is furnish’d with claws on both sides of its body, so is this disease;

(a) “The Clinical Causes of Cancer of the Breast and its Prevention; with Analyses of a Hundred Cases.” By Cecil H. Leal, M.A., M.B. Cantab., F.R.C.S. Eng., Assistant Surgeon to the Cancer Hospital and the Gordon Hospital for Rectal Disease. London: Archibald Constable and Co., Ltd. 1904.

the veins, which are extended from the tumour, represent with it a figure much like a crab." And elsewhere the same Colossus of Medicine gives a more definite account of the pathology of the disease in very concise terms: "When black bile settles in the flesh, if it be of the acrimonious quality, it corrodes the circumjacent skin, and breaks out in an ulcer; but if it be of a milder nature, it generates a cancer, without an ulceration." Celsus observes that: "A carcinoma principally infects the upper parts, as the face, nostrils, ears, lips, and the breasts of women. It has its original from the liver or spleen." Paulus Ægineta harps on the same string; and the notes which he elicits display a generally approximate concord with those given out by his predecessors—with, of necessity, a distinctive *klangfarbe* of their own. He informs those whom it may concern that: "A cancer may be generated in most parts of the body, as in the eyes, the uterus and other places, but especially in the breasts of women, as being of a lax contexture, and very susceptible of the grossest matter. Cancers owe their origin to black bile put in a state of effervescence, and if there be anything of an acid and corrosive quality mixed with this humour, the cancer is attended with an ulceration. Cancers are blacker than other inflammations, but not so hot. The veins all around it are bloated, and distended in the manner of the claws of a crab, whence it took its name *Cancer* (a crab); or, as others will have it, because it adheres with such obstinacy to the part it seizes, that like that animal it cannot, without great difficulty, be separated from it."

So that in the infancy and adolescence of medical science, and for tens of centuries before pathology had arrived at the years of discretion, the general idea of the terrible disease was always specially associated with the female breast. Mr. Leaf has chosen a subject of the widest pathological interest, both in cosmopolitan space and in historical time. An Analysis of a Hundred Cases embodies the results of "special inquiries into the following points: (1) age; (2) state, single or married; (3) family history, especially of cancer or consumption; (4) menstruation; (5) confinements—number of, rapidity with which they follow each other; labour, lactation (presence or absence of), duration of, manner in which it has been performed, use of applications; (6) previous diseases of the breasts; (7) injury; (8) corsets, comfortable or otherwise; (9) worry and anxiety; (10) residency—situation of, near a river, whether dry or damp, climate, drainage; (11) diet—consumption of meat, Australian meat, fish, salt, uncooked vegetables, &c.; (12) alcohol; (13) miscellaneous—general health, occupation, possibility of infection, cancer houses, etc." A glance at this list must convince the reader that hardly any conceivable aspect of the source of the disease, or available standpoint from which it can be critically scrutinised, has been omitted by the writer. Accordingly, the volume offers large claims upon the attention of all surgeons. After the perusal of the preface, the reader must expect a great deal; we only hope that he will not be disappointed. We must leave him to form his own judgment, as the questions raised are far too numerous and comprehensive to be profitably discussed within our necessary limits.

ACUTE ABDOMINAL DISEASES. (a)

In these days, when there appears to be no end to the writing of large text-books and lengthy monographs on isolated subjects, it is refreshing to meet with a small production in which a brave, and we may say a successful attempt, is made to bring into relation a large number of diseases which, though usually considered as separate and essentially different, have in reality many points in common, and probably

(a) "Clinical and Pathological Observations on Acute Abdominal Diseases." By Edred M. Corner, F.R.C.S., Surgeon to Out-Patients, Surgeon to the Physical Exercise Department, St. Thomas's Hospital, &c. Pp. 98. Price 3s. 6d. net. London: Archibald Constable and Co., Ltd. 1904.

spring from a similar, if not identical, cause. This Mr. Corner has done for all the acute infective diseases of the alimentary canal, and he has further shown a complete parallel to exist between the known septic diseases of the skin and those, largely unknown, of the mucous membrane of the alimentary canal.

The aim of the first part of the book is to prove that "Lesions of a similar nature, acute infective necrosis or gangrene, occur in the stomach, the duodenum, the small intestine, the cæcum, the appendix, the large bowel, Meckel's diverticulum, the gall-bladder, strangulated herniæ, and other forms of intestinal obstruction." The author starts by proving that necrosis of the bowel wall depends on two factors—first, the deprivation of the blood supply, and secondly, the infection of the tissues by septic micro-organisms. With the help of numerous cases which he quotes, he shows that the first of these factors is not so potent a one as it is usually supposed to be, owing to the fact that the anastomosis of the intestinal vessels is much greater than is generally thought, and that even if a medium-sized vessel is obstructed, the neighbouring blood-vessels are able to provide a sufficient blood supply to the area normally receiving its blood from the obstructed vessel; even if gangrene does occur in these cases it is limited to a smaller area and is of a subacute or chronic character. Infection with pyogenic micro-organisms on the other hand (which may be either preceded or followed by an anæmia from embolism or thrombosis of the vessels) causes an acute and wide-spread necrosis. This point is specially well brought out by a case which he relates: a male baby, two days old, was operated on for intestinal obstruction, a large meconium, containing Meckel's diverticulum was found, separated from the ileum by three complete twists, the bowel being occluded by the traction of the turns; the torsion must have begun in foetal life, but yet there were no signs of inflammation or necrosis in the cyst; as the meconium was sterile before birth, it was a very rare example of aseptic torsion of the bowel, and a vivid contrast to the usual acute infective necrosis of both diverticulum and bowel usually found in these cases occurring at a later period of life, when the intestinal contents are septic, two examples of which are given.

From this standpoint Mr. Corner gives a new classification of gastric ulcers—(1) Chronic cases, (2) acute cases: (a) acute ulceration or necrosis, which may be likened to a boil in the skin, owing to the thinness of the gastric wall the whole thickness is involved in the slough and a perforation results, as the area of infection is distinctly local and faecal there is little œdema or inflammation of the surrounding stomach wall, and closure by sutures is easy; (b) perforation may occur in but a part of a wider area of septic infection (like one of the many sinuses of a carbuncle), in this case the surrounding tissues are œdematous and inflamed, and suturing is difficult as the stitches tend to tear out. Another interesting point is well brought out in regard to intestinal suturing, as exemplified in the case of enterorrhaphy. The first row of sutures inserted through all the coats of the bowel, must cause necrosis of small portions of intestine by cutting off their blood supply, and are necessarily septic and therefore tend to cut their way out, therefore their use is to make a water-tight joint and prevent the access of septic organisms to the second or serous row of sutures, until the latter have caused a firm adhesion of the two portions of the intestine. Sepsis, therefore, rather than imperfections in stitching causes the failures of anastomosis.

In a section entitled "The Physical Physiology of the Alimentary Tract and Appendicitis," the author says that when the food reaches the ileo-cæcal valve, "it is the duty of that sphincter only to allow water and indigestible *debris* to enter the cæcum." If this is the case, how does he explain the wasting and marked deterioration in health that undoubtedly occurs in cases where an artificial anus is made in connection with the cæcum or commencement of the ascending colon? Though owing to the muscular fibres surrounding the

ileo-cæcal orifice, there may be a slight sphincteric action which prevents the too rapid entrance of the contents of the small intestine into the large, yet surely the main office of this valve is to prevent regurgitation from the large bowel into the small.

The latter part of the book is taken up with the bacteriology of the "Acute Infective Necroses." In this Mr. Corner states very forcibly his opinion that pyogenic micro-organisms are at the root of all these troubles, and that the bacillus coli communis is a much maligned "bug." He explains the frequency of the latter bacillus and the rarity of the former in cultures taken from cases of peritonitis following these acute necroses, by the fact that the bacillus is very easily grown on ordinary media and is a much more luxuriant and hardy grower than the pyogenic cocci, the proof of this being commonly seen in laboratory experiments where the bacillus either obscures or even stops the growth of staphylococci and streptococci. By reference to statistics he shows that the more acute the infection is, as seen in cases of appendicitis, the more frequently are pyogenic organisms found in the peritoneal exudate. Therefore it is probable that even in cases where only the bacillus coli communis is isolated, the pyogenic cocci have first been at fault, but their misdeeds have been obscured by the excessive zeal of the bacilli, which receive the blame. The following sentence sums up the latter portion of the book:—"I believe that we must look to pyogenic micrococci for the starting point of cases of acute perforation and gangrene—i.e., acute infective necrosis, in whatever part of the alimentary tract it may be situated."

Literary Notes and Gossip.

THE *British Journal of Inebriety*, the official organ of the Society for the Study of Inebriety, occupies a unique position among scientific journals. It is a medico-sociological review, which deals with the Alcohol Problem mainly in its biological aspects. The January number contains suggestive notes by Dr. Harry Campbell, on the Drinks of the Early Agriculturists. Dr. C. F. Harford writes on the drinking habits of uncivilised and semi-civilised races. The Pathology of Chronic Alcoholism is discussed by Dr. Ford Robertson, and Dr. Claude Taylor deals with the Pauper Inebriate. The Editor, Dr. T. N. Kely-nack, has an opportune article on the recently issued Report of the Inspector under the Inebriates Acts. The journal is one which should be studied by all interested in the evolution of the human.

MESSRS. LONGMANS have in the Press, under the title of "'N' Rays: A Collection of Papers communicated to the French Academy of Sciences, with additional Notes and Instructions for the Construction of Phosphorescent Screens," by R. Blondlot, Professor in the University of Nancy. Translated by J. Garcin. "N" Rays, discovered by Professor Blondlot, are a peculiar kind of rays emitted by a Crookes' tube, a Nernst lamp, the sun, and many other sources. Their properties, an account of which is the subject of this volume, are quite distinct from those of "X" or Röntgen Rays, and from those emitted by radio-active bodies like radium and uranium.

ON the literary horizon of the New Year has appeared the ninth edition of that popular text-book, "The Diseases of Women and Uterine Therapeutics," by Dr. Macnaughton Jones, with many new plates, and much new material in the text. The seventh edition of Delafield and Prudden's "Text-Book of Pathological Anatomy and Histology" is also before us with a large number of new illustrations, and Erlich's "side-chain" hypothesis has been herein set forth with considerable detail. We have also received a large, and what promises to be an important, treatise on "The Preparation and After-treatment of Section Cases," by Dr. Stewart McKay, of Sydney. The author assisted the late Mr. Lawson Tait in many of his operations, and is imbued with the spirit of the

master. Although now resident in the Antipodes, where, it is understood, he enjoys an extensive surgical practice, he is not unknown in medical literature in this country, where he has published, through Messrs. Bailliere, Tindall, and Cox, an interesting work on "The History of Ancient Gynæcology," and one on Lawson Tait's "Perineal Operations." His new volume is prefaced with a commendatory note by Mr. Christopher Martin, of Birmingham. From Messrs. Wright and Co., of Bristol, we have received another book by Dr. Fernie, entitled "Meals Medicinal," in which he has incorporated the main portions of his former popular little work on "Herbal Simples."

THE *Westminster Review* of January, which has now entered its eighty-second year, shows no sign of decrepitude in the vigorous and interesting articles that go to make up an excellent number. The subjects herein dealt with of special interest to medical men are:—"Behind the Mask," by Chas. Rolleston, a very vigorous and logical essay on hospital administration, in which the writer maintains that many of these institutions "deserve to be prosecuted for obtaining money under false pretences"; and a historical survey of old and new methods in "London Water Supply," by W. J. Fisher. The publication of the *Review* has now been transferred to Messrs. Marlborough and Co., London.

Nor many publishing houses can boast a century of existence. In an interesting brochure before us, Messrs. William Wood and Company, the leading medical publishers of New York, trace the history of their establishment from 1804, when it was founded by Mr. Samuel Wood, to the present time, the firm now consisting of the founder's grandson, Mr. William H. S. Wood, and his three sons. During this period many monumental works have been published by them, notably Ziemssen's "Cyclopædia of the Practice of Medicine," in twenty-two royal octavo volumes, and the "Twentieth Century Practice of Medicine," in twenty volumes, edited by Dr. J. L. Stedman, completed in 1901. The little brochure is published with portraits of the founder and subsequent members of the firm, affording an interesting comparison in costume and personal appearance between 1804 and 1904.

THE MOST COMPLICATED SURGICAL CASE ON RECORD.

THE following narrative by a hospital surgeon, which a correspondent of *The Daily News* vouches to have taken *viva voce* in an interview, is too good to be passed over:—

"What is the most complicated surgical case I can call to mind? Ah! that is indeed a question! I don't know, though, that there's any doubt about it really, when I come to think of it. Captain Castagnette's is the classical case. I'll describe it in un-technical language. He was one of Napoleon's veterans, who began as a private soldier under the Committee of Public Safety. He lost an arm at Valmy. Good soldiers were not discouraged in the straits in which France then was, and he was soon in the field again, but lost a leg at Wattignies. Nothing daunted, Castagnette returned to active service in time to have his face shattered by a shell at Rivoli. It was replaced by a waxen mask; but he went on the Egyptian campaign; the sun melted it, and Napoleon presented him with a silver one.

"He got off without much more serious knocking about until the battle of Jena, when he received a grapeshot in the stomach, which had to be cut away and replaced by a leather one. At Wagram a small shell lodged in the middle of his back. It did not explode, and it could not be removed, in the existing state of surgical science, without danger to Castagnette's life. They left it where it was.

"He went on the fatal march to Moscow, and his leather stomach, which was less exigent in its demands than an ordinary one, was most useful to him in the terrible privations of the retreat. At Leipsig

Castagnette lost his remaining leg and arm, and gained the Cross of the Legion of Honour.

"In 1815 he rejoined the Emperor on the return from Elba, and fought at Waterloo. He had two wooden legs and a helmet with a long spike on it, an idea borrowed from the rhinoceros at the Jardin des Plantes. With this he did some execution, but was struck down and left for dead on the field.

"It was his last battle. Yet it was at the hands of the enemy that he died at the Invalides, fifteen years later. He fell asleep in front of a fire, and his wooden legs became ignited. Slowly the fire crept up, until his leathern stomach began to smoulder. All this time he had, of course, felt nothing; and he never felt anything again, for before he awoke the shell in his back exploded with a deafening report. The only recognisable thing found in the room afterwards was the Cross of the Legion of Honour, which Castagnette had been wearing."

NEW BOOKS AND NEW EDITIONS.

The following have been received since the publication of our last list:—

- BAILLIÈRE, TINDALL AND COX (London).**
The Problem of the Milk-Supply. By F. Lawson Dodd, M.R.C.S., L.R.C.P., &c., &c. Pp. 77. Price 1s. 6d. net.
- Walsham's Handbook of Surgical Pathology: for the Use of Students in Pathology. Third Edition, revised and largely rewritten by Herbert J. Paterson, M.A., M.B., &c., &c. Pp. 529. Price 10s. 6d. net.
- Practical Manual of Diseases of Women and Uterine Therapeutics for Students and Practitioners. By H. Macnaughton-Jones, M.D., M.Ch. Ninth Edition. University Series. Illustrated. Pp. 637. Price 21s. net.
- Some Methods of Hypodermic Medication in the Treatment of Inoperable Cancer. By John A. Shaw-Mackenzie, M.D. Lond. Pp. 32. Price 1s. net.
- The Treatment of Syphilis. By F. J. Lambkin, Lieut.-Col. R.A.M.C., Specialist at Army Headquarters, India. Pp. 160. Price 3s. net.
- The Preparation and After-treatment of Section Bases. By W. J. Stewart McKay, M.B., M.Ch., B.Sc. Illustrated. Pp. 65r. Price 15s. net.
- A Handbook of Pathological Anatomy and Histology. By Francis Delafeld, M.D., LL.D., and T. Mitchell Prudden, M.D., LL.D. Seventh Edition. Illustrated. Pp. 886. Price 25s. net.
- A Manual of Toxicology. By Albert H. Brundage, A.M., M.D., Ph.D. Fourth Edition. Revised and Profusely Illustrated. Pp. 401. Price 8s. 6d. net.
- JOHN BALE, SONS AND DANIELSSON, LTD. (London).**
The Simple Medical Year-Book or Private Medical Ledger. Price 10s. 6d. net.
- The Ambulance in Civil Life and the Proceedings of the Metropolitan Street Ambulance Association. By Reginald Harrison, F.R.C.S. Pp. 70.
- ADAM AND CHARLES BLACK (London).**
Who's Who, 1905. Pp. 1,796. Price 7s. 6d. net.
- Who's Who Year-Book for 1905. Pp. 128. Price 1s. net.
- The Englishwoman's Year-Book, 1905. Seventh year of new issue. Edited by Emily James. Twenty-fifth year. Pp. 368. Price 2s. 6d. net.
- WILLIAM BLACKWOOD AND SONS (Edinburgh).**
Practical Nursing. By Isla Stewart, Matron of St. Bartholomew's Hospital, London, and Herbert E. Cuff, M.D., F.R.C.S. A New Edition. Pp. 436. Price 5s. net.
- J. AND A. CARUCCI (London).**
Reports of the Society for the Study of Disease in Children. Vol. IV. Session of 1903-4. Edited by George Carpenter, M.D. Pp. 378. Price 12s. 6d.

Gall-stones and their Surgical Treatment. By B. G. A. Moynihan. M.S. Lond., F.R.C.S. Illustrated. Pp. 386. Price 17s. net.

JOHN WRIGHT AND CO. (Bristol).

Diseases of the Ear for Practitioners and Students of Medicine. By James Kerr Love, M.D. Illustrated with Fifty-Four Stereoscopic Photographs. Pp. 330. Price 23s. net. Stereoscopes 2s. and 2s. 6d. post free.

Meals Medicinal, with "Herbal Simples" (of Edible Parts). By W. T. Fernie, M.D. Pp. 781. Price 9s.

Obituary.

DR. WM. MORGAN, OF NEWPORT.

Dr. William Williams Morgan, who died at Newport on Saturday at the age of ninety-five, was reputed to be the oldest medical practitioner in the country. Born at Merthyr, he was educated at Aberaeron and at Guy's and the London Hospitals. He took the diplomas in 1835 of M.R.C.S. Eng. and L.S.A., and commenced practice at Newport, where he had ever since resided. Soon after his arrival there he was present at the Chartist riots in the town, which resulted in eleven men being killed. He heard the firing, and tended the wounded where they fell, at the risk of his own life. Dr. Morgan was a personal friend of John Frost, the leader of the Chartist movement in South Wales, who was sentenced to death for his share in the riots, but was respited and transported. His death removes a well-known and highly respected personality from Wales.

DR. THOMAS WOODS, OF BIRR.

It is only a few months since we recorded the retirement from his Poor-law appointment of Dr. Thomas Woods, whose death we now regret to announce. Dr. Woods became a member of the Royal College of Surgeons of England in 1838, and was engaged in the practice of the profession from that time until a few weeks before his death. For over sixty years—since the early 'forties—he was dispensary doctor of Birr, and during the whole of that time no complaint was ever lodged against him. Beside being a successful and beloved practitioner, he was a man of wide interests and reading in science and philosophy. He took an active part with the late Lord Rosse in the construction of the huge telescope which for many years was the largest in the world, and he wrote a book in description of it. Of many other published works, his most considerable was a vigorous and trenchant criticism of the theory of evolution.

DR. WILLIAM CARMICHAEL, OF EDINBURGH.

The death of this gentleman on the last day of the old year came as a severe blow to an unusually large circle of patients and friends. He had gone to London to recruit after an attack of influenza, when pneumonia set in, and he succumbed after a short illness. Dr. Carmichael had been established in practice in a southern suburb of Edinburgh for about twelve years, and was greatly and deservedly respected in the district and beloved by his patients. He was a man of the most sterling worth, absolutely untiring in his devotion to his profession, and without any thought of himself where his patients were concerned. His loss leaves a blank in the lives of many, and his place will be long in being filled. He leaves behind him the memory of an ideal doctor and an honest, upright, Christian gentleman.

DR. J. W. W. PENNY, PORT BANNATYNE, BUTE.

We regret to announce the death of Dr. Penny, Prospect House, Ardbeg, after a very protracted illness, and at the comparatively early age of forty years. He

had been incapacitated from professional work for a considerable period. He was very popular, and his death will be deeply mourned by the people of the island. A younger brother, Dr. David Penny, practises in Rothesay.

JAMES MUNRO, M.D.ED., L.R.C.S.ED., OF DARLINGTON.

DR. JAMES MUNRO, J.P., died on the 4th instant, apparently from heart failure, at the age of 70. The deceased gentleman, who was one of the best known in the town and district, was in his usual state of health on the previous night, and about midnight was preparing to retire to his room, when he became ill. Assistance was soon forthcoming, but he died within a few minutes. The deceased was a native of Scotland, and studied for the medical profession at Edinburgh, where he took the M.D. in 1882, and the L.R.C.S. in 1880. At the time of his death he was Surgeon-Lieutenant-Colonel of the Barnard Castle Militia regiment.

JOHN BOWIE, L.R.C.S., L.R.C.P.EDIN.

MR. JOHN BOWIE died at his residence in Lauriston Place, Edinburgh, on Jan. 3rd, at the age of seventy-three years. Mr. Bowie, who was born at Edinburgh, early evinced a strong desire to enter the medical profession. Pushing his studies in that direction, he soon took a prominent place as assistant to the late Dr. Handyside, and on the death of that gentleman he became chief demonstrator to Sir William (then Professor) Turner. His tastes, however, not lying in that direction, he took up general practice, though urged to adopt anatomy as a speciality. He was much esteemed by a large circle in the city. He is survived by two daughters and four sons, two of the latter being engaged in the medical profession in London. He was educated in Edinburgh, and took the L.R.C.S. and P. Diploma in 1866.

HENRY WILSON, M.D.ST. AND., M.R.C.S.ENG., L.S.A.

THE sudden death is announced of Dr. Henry Wilson, M.R.C.S., L.S.A., of 22, High Street, Waverley, on the 1st instant. Well-known and highly respected in the district, his death will be much regretted. His medical education was conducted at Anderson's College, Glasgow. He qualified as M.R.C.S. in 1868 and M.D. St. And. 1890.

JAMES DOW SAINTER, F.R.C.S. Ed., M.R.C.S. ENG.

WE regret to announce the death at Craigellachie, Banffshire, of Brigadier-Surgeon James Dow Sainter. He was born in 1835, and after finishing his education at the King's School, Macclesfield, studied for the medical profession at the Manchester Royal Infirmary. In 1859 he joined the Army as an assistant surgeon, and he served with the Cavalry Division throughout the campaign of 1860 in China. After a short spell of home service he was ordered to India, and served there, with short intervals in England, until 1877, when he returned home. He was stationed in Manchester until he retired from the Army in 1880.

GEOFFREY EDWARD HALE, M.B.CAMB., OF ETON.

DR. GEOFFREY EDWARD HALE died last Saturday at his house in High Street, Eton, from scarlet fever, caught from a patient, which brought on septic pneumonia. Dr. Hale, who was the eldest son of the late Rev. E. Hale, was educated at Eton, Cambridge, and St. George's Hospital. He took the M.B. and B.C. degrees at Cambridge in 1891, and at St. George's Hospital he won a scholarship and the Acland and Treasurer's prizes, and held staff appointments. At one time he was assistant demonstrator in anatomy and physiology at Cambridge, and contributed on technical subjects to the *British Medical Journal*. Dr. Hale had many friends among the masters and

boys at Eton, where his patient and skilful attendance on all classes and his disinterested sympathy with the poor were highly appreciated. He married in 1894 the eldest daughter of Canon Kynaston, of Durham.

Medical News.

Fire at a County Asylum.

EARLY on the morning of the 9th instant, a disastrous fire broke out in the Bucks County Asylum Stone. The outbreak was discovered by a nurse who was returning from night duty and heard the sound of crackling wood. She at once summoned help and all the inmates were removed to a place of safety. The damage to property was great, but fortunately there was no loss of life. The happy result was clearly in great measure due to the presence of mind of the night nurse, whose name we hope to give in our next issue.

Copyright in Cancer Cinematograms.

SOME years ago Dr. Doyen had cinematograph reproductions made of some operations he performed, these pictures being used for lectures both in France and abroad. It has recently transpired that copies were made and sold to various people, some of whom reproduced life-like pictures of the operations in theatres and booths. Dr. Doyen is reported to be now bringing an action for 200,000f. against the manufacturers, claiming that the pictures are his property.

Proposed Sanatorium at Davos.

LORD BALFOUR OF BURLEIGH presided on Jan. 4th, over a public meeting of English speaking visitors and residents at Davos, held in connection with the proposed Queen Alexandra Sanatorium at Davos for sufferers from tuberculosis who are possessed of only limited means. The first annual report of the Council shows that subscriptions up till June 15th last, amounted to £6,367 19s. 1d. After payment of all expenses to date, including £2,918 towards the purchase of a site, a sum of £2,981 remains in hand.

Death from Hydrophobia.

A REUTER telegram from Victoria (B.C.), of January 3, states that Mr. James Colevin, a prominent shipbuilder of Victoria, who was bitten by a wolf in September, has just died of hydrophobia. This is the first recorded case of hydrophobia in British Columbia.

Radium and Granular Lids.

FROM Berlin it is reported that the ophthalmologist, Professor Herman Cohn, of Breslau, has succeeded in healing granulations of the eyelids with radium. He adds that as yet he has had only three cases of cures, but they were all cases in which other methods had failed, in spite of several months' treatment. Professor Cohn treats each single granulation with the radium, which, for this purpose, is contained in a glass tube. He suggests making extensive experiments in Egypt, where diseases of the eye are so widespread.

Serum Treatment of Anthrax in Worcestershire.

AN important and successful experiment has been made at Kidderminster Infirmary with the serum for the treatment of anthrax. Professor Scavo, of the Institute of Experimental Hygiene of the University of Siena, discovered the value of the serum in question in the course of his experiments, and the attention of our Home Office was drawn to the subject. Dr. Legge, of the Home Office, after visiting Italy, obtained some of the serum, and part of it was sent to Kidderminster Infirmary. Here it has just now been put to a practical test. A patient was admitted to that institution on December 23rd suffering from anthrax. The serum treatment was adopted, and the result is that the patient was sufficiently well to be discharged in eight or nine days. So far as is known, Professor Scavo's serum has only been used in one other case up to the present in this country, and the success which has attended its use in the case which has just occurred in Kidderminster points to it being found a most valuable curative for an extremely malignant disease.—*Standard*.

Notices to Correspondents, Short Letters, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a distinctive *Signature or Initial*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

ORIGINAL ARTICLES or **LETTERS** intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

CONTRIBUTORS are kindly requested to send their communications if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in re-forwarding from office to office. When sending subscriptions the same rule applies as to office, these should be addressed to the Publisher.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

A. K. S. (Surbiton).—Progressive tuberculosis of the lungs is always accompanied by pleurisy. So far your critic is correct. Pleurisy may, however, as everyone knows, be non-tuberculous. In a young adult, unless the cause be adequate and obvious pleurisy and empyema should always be regarded with suspicion, especially if there be a family history of consumption. Send some of the aspirated fluid to a research laboratory to be examined for tubercle.

J. J. THOMSON (Leeds).—We do not know any book that quite fills the gap you mention in medical literature. You should write the MS. to a medical publisher, or if you have not reached that stage, write for advice on the subject.

PUBLIC HEALTH STUDENT.—You should read an excellent paper on the subject of preservatives in milk recently presented to the Essex County Council by Messrs Bernard Dyer and T. S. Dymond. In the course of that article they quote authorities as agreeing in condemning the recommendation of the Departmental Committee on Food Preservatives, with regard to milk. They were all distinctly of opinion that milk containing boric acid, formalin or any other preservative was to be regarded as not of the nature, substance, and quality of genuine milk, and that cases of the kind should be dealt with accordingly.

DR. SHAW MACKENZIE.—We hope to have space for your communication in our next.

MR. J. A. R.—The communication and the accompanying letter have different signatures, kindly explain.

DR. LAFFOON SMITH (Montreal).—Your paper is marked for early insertion.

J. C. R.—Is thanked for his appreciative note and generous tribute to our efforts which we can promise will not be relaxed.

EDINBURGH STUDENT.—A recently issued little book entitled "Medical Laboratory Methods and Tests," by Dr. Herbert French Medical Registrar of Guy's Hospital, would we think exactly meet your requirements.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, JANUARY 11th.

HUNTERIAN SOCIETY (London Institution, Finsbury Circus, E.C.). 9 p.m. Mr. R. Godlee: Shifting Dulness and its bearing on Surgical Conditions. (Hunterian Lecture.)

DERMATOLOGICAL SOCIETY OF LONDON (11 Chandos Street, Cavendish Square, W.).—5.15 p.m. Demonstration of Cases of Interest.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (23 Chenies Street, W.C.).—4 p.m. Mr. J. Clarke: Clinique. (Surgical.) 5.15 p.m. Dr. J. E. Squire: The Elements of Prognosis in Pulmonary Tuberculosis.

THURSDAY, JANUARY 12th.

BRITISH GYNECOLOGICAL SOCIETY (20 Hanover Square, W.).—3 p.m. Specimens will be shown by Dr. G. Elder and Dr. I. Parsons The President: Valedictory Address.

HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne Street, Edgware Road, W.).—8 p.m. Smoking Concert.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 23 Chenies Street, W.C.—4 p.m. Mr. Hutobinson: Clinique. (Surgical.) 5.15 p.m. Mr. A. H. Tabby: Orthopaedic Surgery.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—4.30 p.m. Mr. Cantlie: Beri-Beri.

FRIDAY, JANUARY 13th.

CLINICAL SOCIETY OF LONDON (20 Hanover Square, W.).—8.30 p.m. Papers: Dr. T. J. Walker (introduced by Prof. H. Marsh): Acute Ascending Paralysis in Cases of Chronic Cystitis.—Mr. B. O. Lucas: A Case of Accidental Electrocutation causing extensive Gangrene of all the Extremities.—Dr. W. Ewart: A Case of "Soft Valve" Mitral Stenosis in which no Murmur was heard.

LARYNGOLOGICAL SOCIETY OF LONDON (20 Hanover Square, W.).—4.15 p.m. Annual General Meeting. 5 p.m. Ordinary Meeting. Cases, &c., will be shown by Dr. St. Clair Thomson, Mr. P. de Santi, Dr. H. Tilley, Sir F. Semon, Dr. F. Powell, and others.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (23 Chenies Street, W.C.). 4 p.m. Dr. D. Grant: Clinique. (Ear).

BRITISH ENTOMOLOGICAL, LARYNGOLOGICAL AND OTOLOGICAL ASSOCIATION (11 Chandos Street, W.).—4 p.m. President's address. Paper by J. Sim Wallace. Cases will be shown by the President, Mr. O. Nourse, Dr. Kelson, Dr. Jakins, Dr. Wyatt Wingrave, Dr. McKenzie.

TUESDAY, JANUARY 17th.

THE MEDICO-LEGAL SOCIETY (The Royal Asiatic Society's Rooms, 23 Albemarle Street, W.).—8 p.m. A Case of disputed Fracture of the Clavicle, by Dr. J. G. Garson. Demonstration: The Development of Invisible Finger-prints, by Dr. J. G. Garson. Discussion: The Law relating to the Criminal Responsibility of the Insane, to be opened by A. Douglas Cowburn, Esq.

Vacancies.

King Edward VII. Sanatorium.—Medical Superintendent. Salary £500 per annum, with board, lodging, and attendance. Applications to the Secretaries, 19 Devonshire Street, Portland Place, London, W.

Royal South Hants and Southampton Hospital.—House Surgeon. Salary £100 per annum, with rooms, board, and washing found. Applications to T. A. Fisher-Hall, Secretary.

Ashton-under-Lyne District Infirmary and Children's Hospital.—Resident House Surgeon. Salary £120 per annum, with board, washing and lodging, gas, firing, and attendance. Applications to the Honorary Secretary, Leonard Bottomley, 100 Stamford Street, Ashton-under-Lyne.

Ingham Infirmary and South Shields and Westoe Dispensary.—Senior House Surgeon. Salary £100 per annum, with residence board, and washing. Applications to James E. Wheldon, Secretary, 74 King Street, South Shields.

Royal Dental Hospital of London.—Mechanical Pupil's Department. Demonstrator. Salary £120 per annum. Applications to the Dean of Rochester Square, W.C.

East Sussex District Asylum, Hellingly.—Senior Assistant Medical Officer. Salary £300 per annum, with board, lodging, washing, and attendance. Applications to Reginald Blaker, Clerk to the Visiting Committee, 211, Higher Street, Lewes.

Chester General Infirmary.—House Surgeon. Salary £100 per annum, with residence and maintenance in the house. Applications to the Chairman of the Board of Management.

New Zealand.—Professor of Physiology at the University of Otago. Salary £600 per annum, with half of the Class Fees. Application to the Agent-General for New Zealand, 13 Victoria Street, London, S.W.

Derbyshire Royal Infirmary.—House Surgeon. Salary £100 per annum, with apartments, board, &c. Applications to Walter G. Carnit, Secretary-Superintendent, Royal Infirmary, Derby.

Derbyshire Royal Infirmary.—House Physician. Salary £100 per annum, with apartments, board, &c. Applications to Walter G. Carnit, Secretary-Superintendent, Royal Infirmary, Derby.

Derby.—Medical Officer for High Class Sanatorium, unmarried, with capital, must take half share interest with owner. Applications to C. 43 Howard Street, Derby. (See Advt.)

Appointments.

HAY, A. G., M.D. Glasg., Certifying Surgeon under the Factory Act for the Maryhill (Glasgow) District of the county of Lanark.

JAMIESON, J. W. M., M.B., Ch.B. St. And., Physician to the Dundee, Royal Infirmary.

SADLER, E. A., M.D. Lond., Certifying Surgeon under the Factory Act for the Ashbourne and Mayfield District of the Counties of Derby and Stafford.

Births.

ARMOUR.—On January 6th, at 89 Harley Street, W., the wife of Donald John Armour, M.B., F.R.C.S., of a daughter.

Marriages.

BRAY-LAFFAN.—On January 4th, at St. Mary's Church, Holyhead Major George A. T. Bray, R.A.M. Corps, second son of the late Major-General F. C. Bray, (96th), to Angela, daughter of Dr. Thomas Laffan, of Cashel, co. Tipperary.

CAMPBELL-TAIT.—On January 7th, at St. Mark's, North Audley Street, London, W., Robert Brown Campbell, M.B., Physician, Superintendent, District Asylum, Inverness, to Margaret Amelia, only daughter of William Tait, M.V.O., Windsor.

HART-GUY.—On December 14th, 1904, Herbert Frere Hart, M.B., late R.A.M.C., second son of Colonel E. C. Hart, late Royal Engineers, to Violet May, second daughter of Mr. and Mrs. Gustave Guy, of Groenloof, Fauremuth, Orange River Colony.

TAYLOR-BAKER.—On January 6th, at St. Stephen's, Baywater, William Henry Maxwell, M.A., M.B. Camb. F.R.C.S. Eng., son of the late William Maxwell of Blackheath, to Gladys Dyer, daughter of the late Herbert H. C. Baker, of King William's Town.

Deaths.

BLACKETT.—On January 5th, at his residence, 41 Cambridge Street, London, W., Joseph Bryon Blackett, M.B. C.S., aged 80 years.

BLOMFIELD.—On January 6th, at 20 Peckham Road, Josiah Blomfield, M.D. F.R.C.S., late of Rye Lane, in his 82nd year.

HENDERSON.—On January 4th, at Fordoun House, Waltham Abbey, John Brodie Henderson, M.D., aged 61.

ROBINSON.—On January 4th, at 3 Windsor Terrace, Jersey, Louisa Robinson, daughter of the late Dr. Isaac Robinson, Deputy Inspector, General Medical Staff, aged 67.

STOLTERFOTH.—On January 7th, at 1 Grey Friars, Chester, Maria Augusta Stolterfoth, eldest and last surviving daughter of the late Sigismund Stolterfoth, M.D.

Paris Clinical Lectures.

THE SURGICAL TREATMENT OF FACIAL PARALYSIS.

By FRANCIS MUNCH, M.D.,

Of the Faculty of Medicine of Paris.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

LONG regarded as an affection amenable exclusively to medical treatment, facial paralysis during the last few years has, little by little, fallen into the hands of the surgeon. We hasten to add, however, that it is not claimed that surgical intervention can usefully be invoked in all cases of facial paralysis. It is not proposed to add one more to the list of affections taken from the domain of medicine in favour of more drastic methods. The surgeon merely places the resources of his art at the disposal of patients whose affection has hitherto been regarded as incurable, their treatment having proved refractory to all means at present at the disposal of medical therapeutics. The surgeon thus merely completes the work of the physician, and his intervention, far from taking the place of medical treatment, commences where that ends, in other words, it merely enlarges the domain, and widens the horizon, of curative therapeutics.

The operation proposed in view of the treatment of facial paralysis consists in establishing an anastomosis of the paralysed facial nerve and a neighbouring cranial nerve. The first recorded operation of the kind was performed by Dr. J. L. Faure, on the suggestion of Dr. Furet, in 1898, but it had already been performed by Mr. Ballance in England in 1895. In any event, Faure's proposal found little favour in France, for out of twenty-two observations which I have been enabled to bring together only one is credited to a French surgeon. In most of these cases the intervention comprised a spino-facial anastomosis, the peripheral end of the facial nerve, divided at its point of exit from the stylo-mastoid orifice, was joined in one way or another with the external branch of the spinal nerve or with the branch from this nerve to the trapezius. In seven cases the anastomosis was between the facial and the hypoglossal nerve. The glosso-pharyngeal nerve has also been recommended as an alternative by Schäffer, of Edinburgh, but although the latter operation presents certain advantages from the functional point of

view, its execution is so complicated that few surgeons are ever likely to avail themselves thereof.

The first question we have to ask ourselves is whether the proposed operation is rational. Is the facial graft legitimate in the light of our present physiological knowledge, and is it likely to attain the object in view? In the light of current physiological views we may assume that section of a motor nerve is followed by loss of excitability on the part of the peripheral end, which undergoes what is known as Wallerian degeneration. About thirty days after section of the nerve all that remains is the white matter of Schwann studded with nodules embedded in dried protoplasm. The changes bear on the entirety of the distal segment. The central part, on the contrary, remains intact. The extremity of the axis cylinder becomes slightly swollen, constituting a sort of "zone of growth," which subsequently extends by development of the axis cylinder. If the ends of the divided nerve have been brought together after division the axis cylinder granulates until it reaches the peripheral end, insinuates itself in the old Schwann's layer, and thus nervous continuity is restored.

It would seem, therefore, that anastomosis of the central end of an undamaged nerve with the peripheral end of a paralysed facial nerve, followed by its regeneration, is a perfectly admissible fact from a histo-physiological point of view, at any rate in principle. We must not overlook the fact, however, that in facial paralysis of the third degree, that is to say, the very cases which are reputed to be medically incurable and therefore fall into the surgical domain, can only be identified as such after the lapse of a variable length of time. Whatever the delay, it must necessarily be of considerable duration, and in virtue of the principles enunciated above we must obviously abandon the hope of inducing the "zone of growth" of the central nerve to develop a connection with the fibrous remains which is all that is left of the peripheral part of the facial nerve. For this reason we are unable to attach much importance to the researches undertaken by Manasse and Barago-Clarella in experimental spino-facial anastomosis. In these experiments indeed, the anastomosis was invariably effected immediately after section of the nerves, and they teach us little with regard to the point under consideration, *viz.*, whether, in a grave and therefore ancient case of facial paralysis, we have any chance of obtaining nervous regeneration. These researches, moreover, add nothing to the knowledge already obtained by experiments long since carried out by Philippeaux and Vulpien on the crossed suture of the hypoglossal and lingual, &c., investigations

which conclusively settled the point under discussion without leaving the slightest doubt as to the reality of the fact, *per se*, or on the possibility of the functional restoration after similar nervous conjunctions.

The histological researches carried out by Stewart, at the suggestion of Mr. Ballance, present, from the point of view of spino-facial anastomosis, a vastly greater importance. On the strength of a series of histological researches, both experimental and clinical, these authors were led to conclude, in opposition to the generally received view, that the axis cylinder is in nowise derived from a cellular body situated in the neuraxis or in the spinal ganglia. There is no question of prolongations derived from medullary neuroblasts insinuating themselves in the tissues to reach their muscular or cutaneous termination. According to Messrs. Ballance and Stewart, the axis cylinder is constituted by the fusion of an infinite number of segments. Each of these segments is built up of special cells, which play their part in the structure of the nerve sheaths, the nucleus whereof is attached to Schwann's sheath. In the interior of these cells, Messrs. Ballance and Stewart have witnessed the appearance, some time after division of a nerve, of various elements which subsequently provide, some of them myosine, some a segment of axis cylinder. When the peripheral end of the nerve is not united to the segment that has remained in connection with its trophic centre, these changes soon cease to take place—there is no "maturation." But if union be brought about, the fragments of axis cylinder become fused together and penetrate and traverse the sutures restoring connection with the central end.

It will be seen that this process differs greatly from the classical procedure. The peripheral segment plays an active, indeed a predominating, rôle in the regeneration of the nerve; moreover, the nerve cell, *per se*, no longer occupies the all-important position in the process of repair formerly attributed to it. The axis cylinder is relegated to the simple position of an offshoot of the nerve cell, being made up of the fusion of numerous segments, derived each from a different and non-central cell.

However this may be, the most important conclusion to be drawn from the researches of the English observers is, that the peripheral segment of a nerve, even though it has undergone complete degeneration, after months or even years, although it has become reduced to a mere fibrous cord, preserves, nevertheless, Schwann's nuclei, which remain capable of renewed activity and enable the damaged nerve to become once again a conductor of nervous energy, provided it be linked up with the central segment of another nerve. It follows that the vitality of the nerve is not the point to be considered, since it is assured; it is, indeed, the state of the muscle that should occupy our attention, for upon its contractility will depend, in great measure, the result of our intervention. Obviously, if the contractility of the muscle is lost no nerve suture can be of service; in short, in discussing the propriety of an intervention it is to the muscle rather than to the nerve that we must look.

Most operators now adopt Faure's suggestion to make use of the spinal nerve for the purpose of suture with the degenerated facial nerve. It is important to divide the facial as close as possible to

the stylo-mastoid foramen in order to bring as long a segment of degenerated nerve within the sphere of influence as possible. The simplest plan in regard to the spinal nerve is to make use of the branch to the trapezius, which can easily be isolated at the spot where it enters the body of the muscle through which it has to pass. Some surgeons practise the anastomosis end-to-end, others lateral anastomosis, as, for instance, in the method adopted by Ballance, who splits the sheath of the spinal nerve by a small incision, into which he inserts the end of the facial. This procedure has the advantage of avoiding the paralysis of the mastoid and trapezius, and experience does not show any subsequent dragging thereon. Dr. Faure selected the spinal nerve in preference to the hypoglossus and glosso-pharyngeal, on the ground that it necessitated less manipulation. It must, however, be borne in mind that the destruction of the spinal nerve necessarily entails atrophy of the shoulder muscles with consequent paralysis. Moreover, the spino-facial anastomosis, when successful in restoring contractility of the facial muscles, determines synergical contractions in the shoulder, so that voluntary or involuntary contraction of the shoulder muscles is associated with corresponding contraction on that side of the face. Now the contraction of the facial muscles is, so to speak, the representation of the mental state, and it is obvious that under these circumstances any accidental movement of the shoulder muscles may give the face an expression quite out of keeping with the then mental state of the subject.

This drawback has led certain surgeons to prefer the hypoglossal in spite of the fact that its greater depth renders the operation much more difficult; moreover, the nerve is much smaller. A point in favour of the choice of the hypoglossal is that its cortical centre is much nearer that of the facial than that of the spinal; moreover, the medullary protuberances of the facial and hypoglossus are linked up by the posterior longitudinal tract. It follows that the re-education of the facial muscles, if this be possible, ought to take place much more readily with the hypoglossal than with the facial. Opinions differ as to the advantage attending this special method. Korte, for instance, considers the hemilingual atrophy and dysphagia which have been noted to be much more troublesome than the atrophy of the shoulder; but Bernhardt and Ballance both appear disposed to prefer the hypoglossus in future.

In estimating the value of surgical intervention in the treatment of facial paralysis from the twenty-two cases so far recorded, we must, in fairness, eliminate the "negative cases," that is to say, cases in which the operation is still too recent, and those in which, for special reasons, there was no justification for believing the subjects to be capable of improvement. In most of the other cases the lesion was of comparatively recent onset, rarely exceeding from six to ten weeks. Gluck and Alexander, however, had cases of five years' standing, and Hackenbruch one of nearly eight years' standing. It is possible, however, that the length of the interval between the division of the facial nerve and its anastomosis exerts some influence on the ultimate result, since the best effects were obtained in cases where the division and the anastomosis were performed at one sitting.

The previous duration of the lesion, on the contrary, does not seem to affect the greater or less rapidity of restoration of function, and in this respect the most marked differences have been observed. Side by side with a case reported by Cushing, in which the first symptoms of improvement were noted thirteen days after the operation, or with one by Kennedy, in which movements of the upper eyelid were seen seven days after, there are others, the more numerous, in which months elapsed before the slightest indication of returning muscular power was observed. Speaking generally, it may be stated that we must not expect any marked improvement under six months. The age of the patient does not appear to have much bearing in regard to the return of functional activity.

In the cases in which grafting of the facial nerve has been undertaken hitherto, the paralysis was invariably of peripheral origin. In the majority the nerve was accidentally divided in the course of an operation for aural caries; in others, as the result of wound by firearms, or in association with fracture of the skull. In only one instance (Taylor's case) was the operation performed for paralysis *d frigore*, and not once for paralysis of obstetrical origin. Judging from the published cases, therefore, the indications for surgical intervention are tolerably limited.

To form a trustworthy opinion of the value of this intervention we must have before us a clear conception of its possibilities, and of what may reasonably be expected of it. Treatment of a paralysed facial nerve means attempting to restore to the muscles of the face a motility in every respect comparable with that of the pre-paralytic period. The object in view is the *restitutio ad integrum*, and it is only when this is possible that we are entitled to discuss "the cure of facial paralysis." This being so, we may state forthwith that in cases which have resisted medical treatment, even surgical measures may prove ineffectual so far as concerns complete integral restoration of function. The anastomosis of nerves cannot possibly replace matters in the *status quo ante*. It can only be palliative; in fact, as Dr. Faure puts it, it can only aim at "correcting, in the state of repose, facial asymmetry and restoring tonicity to the paralysed muscles"—so that it is in reality a "cosmetic operation."

The disappearance of the facial asymmetry is therefore the principal—indeed, the only—benefit likely to accrue from the surgical treatment of facial paralysis. This result has been obtained, more or less, in a number of cases, though it is impossible beforehand to forecast with any degree of certainty to what extent the asymmetry will be corrected. It is only fair to add that, even taking things at their best, we are not justified in talking of "complete cure" of facial paralysis in these cases, as is so often done by enthusiastic partisans of surgical intervention. In the more successful cases—by no means in all—the facial asymmetry is modified with the muscles at rest. But it is only with the muscles at rest; for, after as before the operation, the play of the facial muscles is limited to one side of the face, the other half, corresponding to the anastomosis, remaining motionless. The only movements obtainable in this half of the face—after spino-facial anastomosis—are associated movements of the shoulder and face muscles. When the patient wishes to contract the facial

muscles he has to raise the shoulder, so that the facial muscles no longer contract spontaneously in response to emotions, and, therefore, no longer reflect the mental state. In the twenty-two observations only one patient developed movements of the labial commissure in laughing. Even in this instance various interpretations are possible. We know, for example, that according to some anatomists the fibres governing the labial commissures have their deep origin in the hypoglossal nucleus. On the other hand, the association of movements between the shoulder and the face so that the facial muscles contract whenever the shoulder is raised entails manifest drawbacks. The control which some patients seek to impose by grasping the motionless limb with the other hand is at best very imperfect.

We cannot disguise from ourselves that this is a very serious inconvenience. It remains to be seen how far it is possible to check this association of movements by systematic re-education. So far it has not been found practicable to suppress it if any tangible degree.

To sum up, grafting the facial nerve on to a neighbouring nerve may be the means of restoring a certain degree of tonus to the facial muscles, and thus in some measure remedy the asymmetry; but it cannot restore spontaneous movement to the facial muscles while, on the other hand, it often entails inconveniences not devoid of gravity. Moreover, the atrophy of the muscles previously under the control of the anastomosed nerve, which is inseparable from the procedure, is an unquestionable evil. Although in some cases the atrophy of the trapezius or semilingual atrophy does not determine grave constitutional embarrassment, in others the results have been disastrous.

These various considerations explain, perhaps, why this operation, seductively ingenious though it be, has so far attracted comparatively few partisans; indeed, we may well ask ourselves whether it is not likely to be abandoned as falling short of its object, the inconveniences determined by facial paralysis being, after all, less serious than those caused by the operation undertaken for the relief of the former. However this may be, should this procedure acquire a position in practical surgery, it would appear preferable, judging from the observations at our disposal, to select the hypoglossal-facial graft, thus avoiding the more serious troubles resulting from the spino-facial graft.

THE IMMEDIATE
REPAIR OF LACERATIONS
OF THE
PERINEUM:

WITH SPECIAL REFERENCE TO PLACING
THE SUTURES IN POSITION. (a)

By A. LAPHORN SMITH, B.A., M.D.,
M.R.C.S. Eng.,
Of Montreal, Canada;

Professor of Clinical Gynaecology in Bishop's University; Surgeon-in-Chief of the Samaritan Hospital for Women; Consulting Gynaecologist to the Women's Hospital, Montreal, Canada.

The importance of closing up small tears of the vagina and perineum has not so far been generally recognised by the profession. Year by year we have been getting to understand that deaths during the puerperium are due to a great

(a) Read before the Boston Meeting of the American Gynaecological Society, 1904.

many causes, and we see that just in proportion as we succeed in eliminating these causes the death-rate in childbirth is growing less. Infection still remains the greatest cause, and we have still much to do before the whole rank and file of the profession of midwifery realise the importance of making the fewest possible vaginal examinations, and of making even those few as nearly aseptic as possible. But since it is practically impossible to reach perfection in this direction, we must turn our attention to lessening the avenues by which germs may enter the system by immediately closing all tears so as to leave no raw surface in direct connection with the lymphatics. At one time it was thought that puerperal infection took place only through the cavity of the uterus and the tubes, or through the placental site; but since we have been opening the abdomen for the relief of puerperal septicæmia, we know that the infection frequently reaches the blood through the lymphatics, receiving lymph from the perineum, vagina and cervix. In nearly every case I have seen, the chain of lymphatics running up the side of the uterus was filled with pus. More than once I have seen the temperature come down promptly after washing out the uterus and vagina and packing the latter with sterile gauze, so as to stop absorption.

The question of the immediate closing of tears of the cervix has been assigned to other members taking part in this discussion. I heartily endorse all that has been said in favour of it, and I know of at least one maternity hospital where the procedure has been regularly adopted and with marked success. As regards tears of the vagina, they should be sewn up with a running, fine chromicised catgut suture while the patient is still under the anæsthetic. Owing to the ease with which the cervix can be drawn down or forward or backward with a four-pronged forceps, and owing to the great distensibility of the vulva, especially if it is torn, as it generally is when the vagina has been lacerated, there is no difficulty in seeing the tears in the vagina and closing them before closing the perineum. The field of operation can be kept clean by having copious constant irrigation going on, or the uterus can be packed with gauze temporarily to keep the usual trickling of blood from flowing over the vagina.

For the same reasons as the foregoing, namely, to prevent septic absorption, it is important to close even small tears of the perineum. During the last fifteen years I have made a regular practice of putting in a stitch or two in every case in which even half an inch of the fourchette had been torn. The result has been that my patients have been almost entirely free from the slight rise of temperature on the second or third day, which it has been customary to attribute to the milk, but which, I suspect, is due rather to a little septic absorption through these slight lacerations. I am certain that patients who have had these small lacerations of the perineum repaired have made better convalescences than those on whom it was not done. In the case of very considerable tears in the perineum, especially of those which extend through the sphincter into the bowel, the question of loss of function of the muscles of the perineum and of the pelvic fascia is still more important. Emmet has described the results of this accident so well that it is unnecessary to draw attention to it. Every member of this Society knows that the separation

of the levator ani and transversus perinei muscles disables a woman very considerably. Nature, it is true, tries to heal these tears, but she is only able to do it by granulations, which are converted into scar tissue, which in a place so full of nerves as this must cause reflex irritation when the inevitable contraction takes place. There are many other reasons why we should close all tears of the perineum, which are well known to the profession. I once operated on a physician's wife, a beautiful woman and a great social favourite, who was lacerated during her first confinement, and who was practically a prisoner in her room for the next twenty years, owing to the loss of control of the bowels. This in turn led to the wrecking of their domestic happiness, for the reflex irritation ruined her nervous system.

I admit that the immediate repair of the cervix, vagina and perineum is difficult in a poor house with poor light and poor assistants, and it would be better to send for assistance in the form of an expert in plastic work, who, with the help of a nurse and the family doctor, could quickly sew up all tears. But in cases in which such a man is not available, the family doctor himself, if provided with catgut and silkworm-gut ready sterilised, and a few Péan forceps, a few small curved needles, and a good needle holder, and above all, with a large curved perineum needle on a handle, can obtain very good results. The greatest difficulty consists in securing the divided ends of the levator ani muscles and pelvic fascia, which retract at once when torn; for it is of little use to sew up the perineum without taking in the muscles. This difficulty, however, can be overcome by a method which I have devised.

Just before the child's head comes down upon the perineum, the patient is anæsthetised and brought across the bed with the feet held by a twisted sheet or leg-holder. The perineum is sterilised with soap and brush and mercuric chloride, and then, with the large curved needle firmly held in the right hand, and with the thumb of the left hand in the anus and the left forefinger in the vagina, the needle is entered at the base of the lesser lip on the patient's left, and passed rapidly under the vagina and about two and a half inches above the fourchette, coming out at the corresponding point on the woman's right side. A silkworm-gut suture is threaded into it with the right hand and the needle is withdrawn, followed by the silkworm-gut, the two ends of which are caught with a hæmostat. A second one is passed in the same way an inch lower down, but taking in the muscles of the perineum. We can generally tell beforehand, by the rigidity of the perineum, whether the tear is going to be a bad one or not; in the former case we can put in a third stitch, which would take in the sphincter ani on each side of the middle line. Delivery can now go on naturally or artificially, but as soon as the placenta has been delivered the perineum is inspected under a good light and a stream of water, all clots being rubbed off with the finger; the stitches are tied from above downwards, when we shall find that there is absolutely accurate coaptation of the separated parts.

Speaking of the light in the confinement room, especially of the poor, we should always take steps before delivery to provide good light, for two reasons: (1) That we may see how dirty the place is; (2) to see what we are doing. As a rule, a

darkened room means a dirty and badly-ventilated room. In the daytime arrange the patient so that the perineum will be facing a bright window, and if the confinement is likely to take place at night, provide beforehand for a good light easily available for examining the perineum. When we hear physicians say that they never have seen a laceration of the perineum, they may be telling the truth, because they attended all their patients in a dark room.

The presence of the silkworm-gut stitches placed as stated, before the head comes through the perineum and hanging loosely attached by their ends to a forceps, does not interfere with the termination of the labour in any way; not even if forceps are required. If by keeping the pains under control and the head well towards the symphysis there has, happily, been no laceration, no harm is done by their having been introduced; you simply take off the forceps and draw them out. While if the perineum has been lacerated more or less, it is of great advantage to save time and trouble by having them already in, but still more so by having them exactly in the right place to bring the lacerated surfaces together; just as they were before the delivery. I have often heard Emmet say, "They might as well have sewed up her drawers as sew the skin of the perineum," referring, of course, to the failure to restore the muscles; and in many cases in which repair was immediately done I have had to do a secondary operation some years later for the restoration of the muscles.

In conclusion, I would strongly urge every accoucheur to have in his bag a sealed tube with a sterilised needle and catgut in alcohol, and another with six threads of silkworm-gut in alcohol, as well as a needle-holder, a bullet forceps and a perineum needle on a handle. As good light is a great desideratum, a laryngoscopic mirror or headlight would greatly facilitate rapid work.

The placing of the perineal sutures before the tear occurs is an instance in which "an ounce of prevention is worth a pound of cure."

CASE OF REPEATED ANENCEPHALIC BIRTH.

By DAVID RORIE, M.B., C.M.Ed.,
Cardenden, Fife.

In midwifery practice anencephaly is always sufficiently rare to attract notice, and the following case of repeated anencephalic birth is perhaps worthy of being chronicled.

The mother, Mrs. W. A., wife of a miner, is now *æt.* 40, and was married nine and a half years ago. During that period she has been eight times pregnant, and three of these pregnancies have resulted in the birth of an anencephalic foetus, two being males and one female. The detailed history is as follows:—

1. On November 18th, 1895, she was delivered of a full-term male child, pregnancy and labour running a normal course. This child is now alive and healthy.

2. On February 26th, 1897, she was delivered at full term of a male anencephalic foetus. During the pregnancy she complained of being unduly "swelled" in comparison with her previous experience, and in the last three months of severe lancinating pain on both sides of the abdomen. There was the hydramnios usual in such cases, and

labour was precipitate. The child was alive at birth, and survived some fifteen minutes. Ten days after its birth she rose for the first time, and, while sitting in a chair at the fire, was seized with a severe flooding. On reaching the house I found her blanched and practically pulseless. The uterus was relaxed, and it and the vagina full of clot. This was cleared away, and with hot intra-uterine douching, hypodermic injection of ergotin, and rectal injection of salt solution, she was brought round, and thereafter made an uninterrupted recovery.

3. On June 9th, 1898, she was again delivered at full term of an anencephalic foetus, a female. During the later months of pregnancy, she complained as in her previous confinement. Labour was again precipitate and associated with an undue quantity of liquor amnii. The foetus survived its birth for five minutes. I secured this foetus and sent it to Dr. J. W. Ballantyne, of Edinburgh, the well-known authority on teratology. In a letter he very kindly sent me at the time, he said:—"While such cases are very rare, it is a curious fact that it is not at all uncommon for a woman to give birth to two in succession, and even to three. I have noted two or three such cases." This statement is interesting in the view of later events. Later, he wrote again:—"The frozen section turned out very well, and showed, in addition to the anencephalic peculiarity, some torsion of the spine and absence of vertebral bodies."

4. On November 26th, 1900, she was delivered of a full-term male child, now alive and healthy. As the husband was very anxious that "something should be done" to secure the advent of a healthy child, the mother was, after the first month of her pregnancy, kept on a preparation of aletris farinosa. Pregnancy and labour were of a normal character.

5. On September 9th, 1901, she was delivered of an anencephalic male foetus at full term, the circumstances of pregnancy and labour being similar to 2 and 3. The pain of the later months of pregnancy, however, was much more severe, and on several occasions required the administration of opiates. I was not made aware of the pregnancy until she was in the seventh month of it, and no drug treatment was followed throughout it as in 4.

6. On February 6th, 1903, she was delivered of a full-term female child, now alive and healthy. Pregnancy and labour were natural, beyond the existence of a certain amount of hydramnios (not noticeable in 1 and 4), and throughout the pregnancy she took the preparation of aletris.

7. On August 3rd, 1904, she aborted at the fourth month. As far as I could make out, the foetus presented appearances natural to its stage of development.

At the date of writing the patient is again pregnant, is taking no drugs, and it will be a matter of interest to note the result.

Mrs. W. A. is a well-developed woman, of middle size, and more than average intelligence. The family circumstances are good. She is somewhat prematurely grey, but is not of a neurotic temperament. Until the birth of the third anencephalic foetus, she was not made aware of the foetal deformity, only knowing that they did not survive their birth. The husband is a healthy man of the same age as herself, and there is no history of

syphilis nor of other hereditary taint on either side. The three surviving children are in every way healthy and well developed for their age.

TWO CASES OF LUMBAR COLOTOMY :

WITH REMARKS ON THE ADVANTAGES OF
THE LUMBAR ROUTE.

By HERBERT SNOW, M.D.Lond., &c.,
Senior Surgeon, Cancer Hospital.

CASE I.—Mr. J. A. B., æt. 63, was first seen on January 8th, 1904, with very advanced rectal cancer of about three years' duration. The whole circumference of the higher rectum was infiltrated, being hard, nodular and fixed. There was an enlarged gland in the left groin. The patient was a small, wiry-looking man. The urine was loaded with albumin, and there was much vesical irritation, in addition to the straining at stool. Morphia with cocaine was prescribed, and a glycerine with peppermint-water enema on alternate days.

Much relief was experienced until May, when it became evident that complete obstruction was impending. The tip of the finger could barely be passed into the diseased gut, the abdomen became greatly distended, and the intense suffering could no longer be alleviated. On May 27th, I performed left lumbar colotomy, with the valued assistance of my colleague, Mr. Ernest Miles. Considerable difficulty was experienced in hooking up the bowel, as the space between the last rib and the iliac crest barely exceeded one inch; but eventually the colon was sutured in Petit's triangle, and opened. For the next four days, frequent injections of glycerine were introduced for the removal of an enormous accumulation of hard scybala. The temperature was 99° throughout. The wound cicatrised in a fortnight. Within six weeks from the operation, the patient had gained nine pounds in weight. On May 27th, the fæces passed wholly from the loin, and the albumin had disappeared. In September, the patient cycled from London to Mitcham. He now goes about with a belt, and is able to enjoy his life, taking morphia with cocaine by the mouth, and also smoking opium occasionally. The disease has not made any visible progress since the colotomy. Nothing escapes *per anum* except a little flatus.

CASE II.—Ada L., æt. 22, married, two children, youngest æt. 9 months, was admitted into the Cancer Hospital on June 22nd, 1904. A haggard, emaciated woman, with every indication of poverty and neglect. Immediately beyond the sphincter ani, the finger passed within dense, hard tissue, whose upper limits could not be reached. The recto-vaginal septum was infiltrated as high as the posterior fornix. There were enlarged glands in both groins, and masses of the same above Poupart's ligament. On July 1st, it was found necessary to perform left lumbar colotomy in the usual manner, with great relief. The temperature subsequently was normal or subnormal. On September 20th, the note runs: "Comfortable; no pain; occasional slight anal evacuation, but nearly all passes by the side. Very weak and emaciated. Both legs œdematous." Death took place on October 4th. An autopsy showed infiltration of the rectum and sigmoid flexure for twelve inches above the sphincter. A large mass of cancerous deposit filled the pelvis, and implicated both broad ligaments. Hardly any lumen was to be felt at two inches from the anus. There were extensive metastases in both right and left supra-clavicular and cervical glands, in the axillary, bronchial and mediastinal glands. The ovaries, Fallopian tubes and bladder were infiltrated. The lower third of the uterus was enveloped by the growth.

Remarks.—The early age of the last patient, and the remarkable extensive deposits found, make the case noteworthy. I have not previously seen rectal cancer at so early an age. But apart from this consideration, the operation of lumbar colotomy seems now to have become obsolete; and any instance of its performance

is probably interesting on account of the rarity alone. The ease with which under ordinary circumstances the bowel can be reached in the inguinal region is presumably the main reason why the time-honoured procedure, once so well known in association with the names of Amussat, Callisen, and Hilton, are now altogether neglected.

Yet the inguinal route is by no means without its drawbacks, and the old-fashioned lumbar operation has much to recommend it. It seems to be forgotten that in the latter we open the bowel at least two inches higher up than in the former; that is to say, at the junction of the transverse with the descending colon, instead of at the sigmoid flexure. This does not much matter when the lower part of the rectum only is involved; but materially counts, both for immediate safety and for future advantage, when there is disease of the higher. More than once in an inguinal colotomy I have seen the meso-sigmoid in a state of extreme hypostatic congestion from proximity to the lesion. I have known seven or eight deaths from inguinal colotomy, and believe that if all cases were published, a high rate of mortality would become apparent. On the other hand, I have never heard of a death following the lumbar incision.

In both the cases above recorded, it would almost certainly have been impossible to bring the sigmoid flexure into an inguinal wound. In both, the first especially with marked albuminuria, it was essential to avoid unnecessary shock. In both, the natural progress of the growth was certain to complete the blockage, and to ensure full evacuation by the loin. In one, the extensive deposits, probably unprecedented, obviously precluded more than a few months' survival. In the first, the prompt disappearance of copious albumin from the urine after operation was concomitant with marked improvement in general health, which has continued to the present time.

It has been proved that a meso-colon exists on the left side in 36 per cent.; on the right in 26 per cent.; while in 52 per cent. this is wanting on both sides (Treves). Therefore, the chief advantage of old claimed for the lumbar route, that it avoided a peritoneal opening, is largely without foundation in actual fact. Yet the position of the wound ensures such close natural apposition of peritoneal edges as to have been in those days practically commensurate in safety to an extra-peritoneal operation. In both the preceding cases, the peritoneum was opened freely. The great point for future benefit is to secure the gut as high up as possible, and at as acute an angle as possible, thus ensuring a good spur. Difficulty in bringing up the colon is best met by a silk ligature passed temporarily through the entire lumen, merely for traction purposes.

Special Articles.

ASSOCIATION OF MEDICAL DIPLOMATES OF SCOTLAND.

A MUCH-NEEDED powerful organisation has recently been formed under this title, the first President being Dr. Claude St. Aubyn Farrer, with the following Vice-Presidents: Dr. Clouston, President of the Royal College of Physicians, Edinburgh; Sir Patrick Heron Watson, President of the Royal College of Surgeons of Edinburgh; Sir John Halliday Croom, Vice-President of the Royal College of Surgeons of Edinburgh; Dr. Henry E. Clarke, C.M.G., President of the Faculty of Physicians and Surgeons of Glasgow; Sir Alfred Cooper, F.R.C.S.Ed., Vice-President of the Royal College of Surgeons of England; Sir James Clarke, Bart., C.B., Sir Anderson Critchett, Sir John W. Reid, K.C.B., Sir John Sibbald, Sir John Tyler, C.I.E., Sir William Whittla, with Dr. William Bell as Hon. Treasurer, and Dr. David Walsh, Hon. Secretary.

Year by year the *Medical Register* contains the names of a large and steadily increasing number of medical men holding Scotch qualifications and practising in England, Ireland and Wales. Hitherto, these practitioners have lived in a sort of "No-man's Land," for they have been

for the most part out of touch with their own Colleges, with the local hospitals and societies, and, truth to say, with each other. To bring these scattered forces into line for the protection of common rights and interests, and for the removal of social and professional disabilities, is clearly a matter of common-sense prudence. Already the hearty response to the circulars issued by the Medical Diplomates of Scotland bears every promise of a full and brilliant future.

The Association has now assumed a definite shape. Rules have been drawn up, and a strong and energetic Council appointed. Broadly speaking, the objects of the Association may be defined as follows:—(1) To bring about a firm and lasting union between Scotch diplomates in town and country. (2) To advance the common interests of Scotch diplomates. (3) To provide a central meeting place for the transaction of all business that may come within the scope of the Association.

There are three directions in which the Association has decided to appeal to members:—

1. SOCIAL.—The Council hope to foster and encourage social intercourse among members by the agency of annual dinners, presidential and other addresses by distinguished men, *conversaciones*, smoking concerts, excursions, and the like. Some day, as the Association grows in strength, it may be possible to hold an occasional meeting outside London.

2. SCIENTIFIC.—The proposal to add another to the many existing scientific societies will naturally require abundant justification. To put the matter briefly, the Council think there is room for such a Society on the following lines, especially as there is reason to believe many Scotch diplomates have to some extent held aloof from local associations. They suggest the discussion not so much of abstruse and highly technical scientific questions as of common disease in relation to the everyday work of general practice. The presence of consultants, specialists, and general practitioners at these discussions would necessarily result in a crop of information of wide suggestive value. At the same time the Council feel it would be unwise to confine the work of the Association to abstract discussions. They propose that scientific meetings be held twice monthly during the Winter Session, and that alternate meetings be devoted to clinical cases, exhibition of drugs, instruments and other appliances, pathological specimens (including microscopes), radiograms, improved laboratory methods, in short, any matters likely to be useful to members in the practice of their profession.

3. MEDICO-POLITICAL.—A fair share of the formal meetings might be devoted with advantage to the many problems which fall outside the purely scientific aspect of professional life. In this way the Association would first of all form the natural mouthpiece of the Scotch diplomates as regards their rights and privileges in relation to those colleges from which their medical qualifications have been obtained. Hitherto, it has been the custom of the Scotch Colleges to act independently of the opinion of their diplomates, indeed, owing to the absence of any collective organisation, it would have been impossible to ascertain the views of their constituent *dicentiates*, members and fellows.

Medico-political matters with an everyday bearing on medical practice may be found in such subjects as—Hospital Abuse; Midwives Bill; Suppression of Quacks; Disabilities of Scotch Diplomates in Hospital Appointments (out of Scotland) and Otherwise; School Diseases; School Board Certificates and Medical Certificates generally; Police; Poor-law; Club and Dispensary Practice; Bills before Parliament; Medical Titles; and generally, anything concerned with progress in professional matters.

We understand that already nearly 200 members have given in their names, and the Council reminds all Scotch diplomates that everyone who joins in these earlier days will greatly strengthen the foundations of the A.M.D.S. (a)

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

MEETING HELD JANUARY 13TH, 1905.

The President, DR. FREDERICK TAYLOR, in the Chair.

MR. JONATHAN HUTCHINSON, jun., showed a case two years after intra-cranial resection of the second division of the fifth nerve. The case had been described in the Society's "Transactions, 1904," and adverse opinions were expressed as to the ultimate future of the case. The operation—that of nerve section between the Gasserian ganglion and the foramen rotundum—had been undertaken for epileptiform neuralgia attacks. Since its performance, the man had been entirely free from attacks and had suffered no inconvenience from the anæsthesia. He had several times travelled to and fro between South Africa and England, being exposed to much wet and cold—the most severe test possible.

ACUTE ASCENDING PARALYSES IN CASES OF CHRONIC CYSTITIS.

DR. T. J. WALKER had had in his practice three cases of long-standing chronic cystitis which had terminated fatally by a most rapid acute ascending paralysis. The first case was that of a baker who, at the age of fifteen, injured his urethra by falling astride a rail and who was under treatment for recurrent stricture and chronic cystitis from the age of twenty-five to forty years, but who was able to follow his work. An exacerbation of the chronic cystitis had occurred about a month previous to his final attack, for which he was under treatment, when in the course of a night the patient felt numbness in the feet and some loss of power in the legs. When seen the next morning there was paresis of the limbs up to the thighs and by that evening paralysis had extended upwards to the arms and thorax, the breathing became embarrassed and he died eighteen hours after the onset of the paralytic symptoms. There was no *post-mortem*. The second case was that of a farmer who was seen when *æt.* 52, with a stricture of the urinary meatus, for which he had sought relief only when retention and cystitis had made his life intolerable. For the following ten years the patient continued to have cystitis. At the age of sixty-two an exacerbation of the chronic cystitis occurred; this had been present for four days, but without retention, when in the early morning the patient experienced uncomfortable sensations and some muscular feebleness in the limbs. At midday there were distinct signs of paraplegia; on the following day there was considerable progress of the paralysis, and he died forty-eight hours after the first sign of its commencement. There was no *post-mortem*. The third case was that of a butcher, *æt.* 67, who had suffered for many years from chronic cystitis, and for the previous three months had required catheterisation on account of prostatic disease. He had been confined to his bed for some time, when, on getting out, he appeared feeble and unsteady. Twelve hours later there were distinct signs of paralysis of the arms, and the patient died eighteen hours after the first onset of the paralytic symptoms. There was no *post-mortem*. Dr. Walker referred to a case termed urinary paraplegia by Stanley, of a man admitted into St. Bartholomew's Hospital under Earle with gonorrhœa and phimosis, who died three weeks later, twelve hours after paraplegia had set in. Another case had occurred under Dr. Saunders in Birmingham. The author then discussed the pathology of Landry's paralysis and concluded that the connection is not a reflex nervous one, but an extension of microbes from the bladder to the spinal cord.

MR. CLEMENT LUCAS noted that in each of the cases described there had been cystitis of very long standing. Thus the connection between the cystitis and the paralysis was not a close one. He suggested that the cystitis was not causally related to the paralysis, but that this merely occurred in a person exhausted through long illness, which by chance happened to be cystitis.

Dr. FARQUHAR BUZZARD regarded the term acute ascending paralysis as being in this instance quite justifiable. He had pointed out on several occasions that Landry's paralysis was by no means synonymous with acute ascending paralysis, but was a term that should be restricted to the one of the three varieties of this condition, in which only very slight lesions in the cord could be detected after death. He would have expected to find in Dr. Walker's cases that marked changes had been present in the spinal cord and membranes, the conditions being an acute meningo-myelitis. This condition might be caused by a number of different organisms, such as the meningococcus, the gonococcus, those of the acute specific fevers, &c.

Mr. WALTER SPENCER drew attention to the resemblance of the condition to paralytic or "dumb" rabies that occurred in rabbits experimentally, and as a terminal phenomenon in canine rabies; there was reason to suppose that in man this form of hydrophobia might occur.

The PRESIDENT remarked on the extraordinary rapidity of the cases; he had never seen such a case. He deprecated the use of the term Landry's paralysis to describe such a condition.

Dr. WALKER, in reply, said that in a long practice he had never met with any such cases except in combination with chronic cystitis, and so could not but believe that a direct causal relation existed between the two. In the last two cases he had been able to accurately predict the course of the affection, a prediction unfortunately verified. He was not surprised that such cases had not been recorded, because the connection had never been noted. Indeed, even such a definitely recognised condition as urinary paraplegia, quite different from the one he had just described, was not alluded to in many books on urinary diseases.

CASE OF ACCIDENTAL ELECTROCUTION CAUSING EXTENSIVE GANGRENE OF ALL EXTREMITIES.

Mr. CLEMENT LUCAS described such a case in a boy, æt. 15, who had been admitted into Guy's Hospital, March 4th, 1904. The lad, an employé at the London Electric Supply Corporation station in the Blackfriars Road, was standing on a discharged barred shaped transformer so as to dust a ledge. He slipped and clutched at a cable, through which a current of 10,000 volts tension was passing. He was only in contact with this for thirty seconds. Respiration at once ceased, the limbs were burnt, swollen and stiff. Artificial respiration was immediately resorted to and the boy came round. On being seen soon after at Guy's, some shock was present, though this was not profound; the radial pulse could not be felt; he was conscious. The right hand was dead, white, strongly flexed and supinated; the arm showed solid œdema up to the shoulder; the forearm was crimson and peeling. The left hand suffered far less. Both feet were badly burned, there was anæsthesia and paralysis for four inches above the ankles. An everted wound in the axilla showed the point of exit; this was just behind a metal clasp of the braces. On the third day the right arm was amputated through the shoulder-joint, a short deltoid flap being used. Arterial thrombosis was found up to the origin of the superior profunda. He stood the operation well, and, as on the third day after the gangrene began to spread, both legs were amputated. Toxæmia set in, and death occurred on the ninth day after the accident. Other similar cases of recent occurrence were referred to and the condition discussed.

Mr. ASPINALL gave an account of the electrical engineer's aspect of the subject. He divided injuries from electricity into two groups—according as to whether the body came into the circuit or not—*i.e.*, as to whether the current flowed through the body or not. In the first group there were four varieties; high tension shock with good or bad contact, low tension shock with good or bad contact. He defined high tension as being of over 750 volts. In the second group, where there was no arc formed, he separated cases due to fright from those due to shock. He suggested that burning was inverse to the amount of shock. Mr. Lucas' case was an instance of severe burning due to an

enormous voltage and yet the lad came round. He had seen cases like Mr. Lucas' recover for a time after the passage of 20,000 volts through the body. In fatal cases it was rare to find burning. He remarked on the peculiar character of the cry that occurred in the shock cases, a characteristic sound, half sigh and half groan. Even after a fatal shock a man might speak, though this was rare. He advanced the suggestion that the vapour formed by the volatilisation of various metals or other substances might prove a factor in some rare cases, through aspiration of this into the lung.

Dr. WILFRED HARRIS agreed with Mr. Aspinall that the essential fact was not the actual voltage but the horse power behind it—*i.e.*, the current was the important thing. No harm ensued from a voltage of 100,000 or higher if this was of slight amperage, as in a static machine or X-ray apparatus. The amount of burning was inverse to the amount of current, and therefore of danger. Any resistance therefore increased the one and diminished the other. This was instanced by the irritation of a failing battery when the pad was dry, and its lessening after wetting the pad.

Mr. WALTER SPENCER read the following abstract of a communication on

ELECTRO-PATHOLOGICAL INJURIES FROM LIGHTNING STROKE AND ELECTRICAL CURRENTS OF HIGH TENSION, by Dr. S. Jellinek, Medical Officer in the Royal and Imperial Hospital of Wieden, Vienna.

Electrical currents are harmful according to the tension of the current and the resistance of the human body. A tension of 150 volts demands precautions, a tension of 200 volts and more may be dangerous; a tension of 500 volts may be fatal. But the harmful character of the tension is affected by the resistance. A man was killed near Prague by a current of 95 volts, when standing barefoot in a mixture of potash and sugar. On the other hand, an electrical employé in Vienna, though much damaged, was not killed by a current of 5,500 volts. Under resistance there is to be considered the resistance of entry and the resistance of exit. As regards the resistance of entry, there is the condition of the clothes dry or wet, or of the skin. The dry, horny palm of a workman may present a resistance of as much as 100,000 ohms; soft, moist skin, also lesions of the skin, have a very much diminished resistance, whilst the resistance of the mucous membrane of the mouth falls below 1,000 ohms. The resistance of exit depends upon the nature of the ground, also as it is usually the feet which connect with the ground, the covering of the feet. An electrical employé may come in contact with currents of high tension and do so with impunity, if the feet are covered with non-conducting material. In the case of the workman above mentioned standing barefoot in potash and sugar, the resistance of exit was very small indeed. The condition of the ground is most important; in private houses and in some mills the ground forms a good protection; mineral acid factories and coal mines, on the other hand, especially favour the occurrence of an accident. In making rules for the prevention of accidents, rooms and shops containing electrical installations should be distinguished according to the tension of the current and the nature of the ground into "the safe" and "the dangerous."

Mr. LUCAS replied.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

MEETING HELD FRIDAY, JANUARY 6TH, 1905.

The President, Dr. H. C. EARL, in the Chair.

ANÆMIC INFARCTION OF LIVER.

PROFESSOR O'SULLIVAN, for Dr. Roy Dobbin, showed specimens from a case of extensive anæmic infarction of the liver. The case was one of puerperal eclampsia, with jaundice. A large gall-stone was impacted in the upper end of the gall-bladder. The smaller branches of the hepatic artery showed an extensive degeneration of the walls, commencing in the muscle cells of the middle coat, and accompanied by

a similar change in the walls of groups of capillaries in the neighbourhood of the branches of the artery. The degenerated material took on Weigert's fibrin stain deeply, and gave none of the amyloid reactions. Hyaline thrombi were present in some of the arteries. The walls of the hepatic and portal veins were healthy. Some of the portal veins inside the infected areas were thrombosed.

ENDOTHELIOMA OF UTERUS.

The PRESIDENT and Mr. MAUNSELL showed an Endothelioma of the Uterus.

Professor O'SULLIVAN thought that in the present state of knowledge in regard to endotheliomata, unless one could establish the transition from the ordinary endothelium of the lymph space to the tumour endothelium, the diagnosis was not justified.

The PRESIDENT agreed with Professor O'Sullivan's remarks, and admitted that there were many parts of the tumour from which nobody could possibly establish a diagnosis.

MYOMA OF RECTUM.

The PRESIDENT showed a Large Myoma of the Rectum which was removed by Dr. Frank Golding, of Headford, from a woman during parturition. The tumour measured three and a half inches in its longest diameter by two and a quarter inches in its shortest. It presented some patches of calcification near its surface. It was attached to the wall of the rectum by a thin membrane.

Dr. TRAVERS SMITH asked was there any possibility of it being a uterine tumour which had found its way out *per rectum*?

The PRESIDENT said he did not think it was a uterine myoma, because he believed that if a patient had had a myoma like that eating into her bowel, she would have complained about it. Dr. Golding had also given a distinct history of its having a membranous attachment, which would not have been present if the tumour had eaten its way into the rectum.

POTT'S CARIES.

Mr. GUNN exhibited a case of Pott's Caries.

GASTRIC ULCER.

Mr. GUNN showed a Gastric Ulcer which he thought was of a tuberculous nature.

Professor O'SULLIVAN said he would like to ask the reason for supposing the ulcer to be tuberculous. The rarity of tuberculous conditions in the stomach made it worth while to examine it carefully if it was supposed to be tuberculous.

Mr. GUNN said the reason he thought it so was that there was old tuberculous disease of the abdomen and active tuberculous of the lungs, the patient probably swallowing a lot of the sputum. The ulcer was also tuberculous-looking, having thin, undermined edges.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

CLINICAL MEETING HELD FRIDAY, JANUARY 6TH.

C. M. TUKE, Esq., President, in the Chair.

Dr. Z. MENNELL showed a typical case of Acromegaly in a man, *æt.* 42. In 1883 he enlisted in the army, and his measurements were as follows: Weight, 10½ st.; height, 5 ft. 10½ ins.; chest, 37 ins.; and circumference of head, 21 ins. From 1887 until 1902, he had constantly to get larger boots, hats, gloves, and clothing, when latterly he could not get stock sizes large enough, and his measurements at present are: Weight, 19 st. 3 lbs.; height, 6 ft. 1 in.; chest, 47 ins.; and head, 25½ ins., which measurements have remained about the same during the past two years. His personal health is good, his only subjective symptom being occipital headache, with depression of spirits.

Dr. A. MORISON showed (1) a case of old-standing Mitral Stenosis with persistent choreic movements in a man, *æt.* 76. At the age of 14, he first had an attack of rheumatic fever, followed by clonic convulsive movements of the right arm; and when *æt.* 30, he had a second attack which was followed by a similar affection of the left arm; and (2) that of a man, *æt.* 51, with a

"renal heart," associated with granular contracted kidney.

Dr. J. B. BALL exhibited a man, *æt.* 52, with Tonsillar Disease of about six months' standing, commencing with considerable enlargement of the right tonsil and surrounding tissues, which eventually supplicated and discharged a quantity of necrosed *débris*, leaving a large, ragged cavity. Although there was no history of syphilis, it was considered to be gummatous in nature, and the case seemed to improve under anti-syphilitic treatment at first. A small portion of the tissue has lately been examined microscopically, showing the disease to be of a malignant type. Dr. Ball considered it to be a case of combined syphilitic and malignant disease.

Dr. A. GASTER suggested the patient be treated with large doses of mercury before accepting the case as one of pure epithelioma.

Mr. G. PERNET also suggested a course of mercury under strict observation, and apart from iodide of potassium.

Mr. R. W. LLOYD said that *local* mercurial treatment, combined with internal administration of anti-syphilitic remedies, might prove useful.

Mr. J. T. ARMSTRONG did not agree with the mercurial treatment, taking into consideration the microscopical report, and suggested antiseptic applications locally.

Dr. J. B. BALL briefly replied.

Mr. JOHN GARRETT brought before the notice of the Society a case of Granuloma Annulare, which occurred on the back of the right hand of a girl. It commenced as a papular rash about six months ago, the papules disappearing and leaving an indurated elevated margin around the centre, which regained its normal condition.

Dr. COLCOTT FOX said the disease was a very rare one, the etiology of which was unknown.

Mr. G. PERNET was of opinion that this case was not one of granuloma annulare, and showed microscopical sections of the latter disease.

Mr. D. J. ARMOUR showed a girl, *æt.* 26, upon whom he had operated for a Bilateral Ankylosis of the jaw. Both condyles were found to be fused with the zygoma, forming a solid mass of bone of ivory-like hardness. The zygoma just in front and behind the tuberosity and the neck of the jaw were cut through on each side, and the jaw was subsequently moved several times under *anæsthesia*. The patient can now separate her jaw easily and well, and is able to eat solid food, for the first time in her life.

Mr. D. J. ARMOUR also showed a specimen of a Polycystic Kidney which he removed from a woman, *æt.* 29, who made an uninterrupted recovery. Since the operation she has improved in health and is passing a normal amount of urine.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, JANUARY 15th, 1905.

FEVER AND SWEATS OF PHTHISIS.

It is well known that consumptive patients support a high temperature without any apparent inconvenience. Frequently patients can be found amusing themselves having 102° of fever. In such cases, says Professor Tyonnel, it is not necessary to interfere. But in other cases, on the contrary, the fever is very high, fatiguing the patient, and treatment is necessary.

Amongst the antipyretics at our disposal, antipyrine is the most innocent of all, and may be given with quinine:

Hydrochlorate of quinine, grs. v;
Antipyrine, grs. x.

Two to four daily.

If the antipyrine is not well borne by the stomach, it should be given with Vichy water.

Pyramidon lowers the temperature very quickly, but it frequently excites profuse sweating. Preference might be given to the acid camphorate of pyramidon in wafers of grs. x; three or four daily.

Phenacetin is also a good remedy, and may be associated with quinine and pyramidon :

Phenacetin, grs. v ;
Hydrochlorate of quinine, grs. iv ;
Acid camphorate of pyramidon, grs. vj.

For one wafer. Three of four in the twenty-four hours.

Sometimes simple rubbing with eau de Cologne or lavender spirit every evening acts favourably and is inoffensive.

Atropine is without doubt the most active agent, although not without danger. Some patients complain of dryness of the throat from its use, and say that they can no longer expectorate, while others present cerebral trouble.

Camphoric acid, white agaric, and ergot of rye often succeed and may be combined as follows :

Belladonna powder, gr. $\frac{1}{2}$;
White agaric powder, grs. ij ;
Ergot of rye, grs. iij ;
Camphoric acid, grs. x.

For one wafer. Two to three in the course of the evening.

TIC DOULOUREUX.

Tic douloureux of the face is well known where, during the attack, the muscles of the affected side are agitated by convulsive movements, which give to the physiognomy a grimacing attitude.

The malady (neuralgia) is very rebellious, resisting all kinds of antineurine agents, nor is it amenable to the electric current. Local injections of cocaine, stovain, morphine, phenic acid (2 per cent.) have been tried without much durable success. The resection of the painful branch or even Gasser's ganglion, or the superior cervical ganglion of the sympathetic nerve, alone has given satisfactory results. But this operation is very complicated, and many patients refuse to be so treated.

Sometimes the teeth have been incriminated ; but they have been extracted one by one without affording any relief. Cruet recommends incision of the gum down to the bone and the application of the thermocautery. This method, however, does not always succeed. In such a case, where the operation had given no relief, Dr. Sondaz tried the injection of proof spirit beneath the gum as practised by Prof. Pitres, of Bordeaux, for facial neuralgia. With an ordinary hypodermic syringe, M. Sondaz injected twenty drops of alcohol at 60 per cent. deeply under the mucous-membrane of the gum at the point where the pain seemed to start from. The injection produced a burning sensation, but was well supported by the patient. The following day the part was considerably inflamed, but rapidly diminished, while the pain was much relieved. A week subsequently another injection was made, but the consequent inflammation was much less marked, and the tic had completely disappeared.

The method seems to be very efficacious, and may be tried in all cases of neuralgia unrelieved by the ordinary treatment. The injections of alcohol produce a cessation of the pain and provoke slight and painless neuritis, which in its turn causes degeneration of the nerve cells.

A WONDERFUL PATENT MEDICINE.

The other day a long, lanky, and haggard man was brought up before the police court at Paris as being a vagabond. The magistrate asked him what was his profession. He replied that he sat as a model for a patent medicine against obesity ! Astonishment of the magistrate, who asked him to explain.

"I will tell you, your worship. I am engaged by a manufacturer of a drug, the virtues of which are supposed to rapidly diminish corpulency. I put on a whole garment of indiarubber and am blown out, just like the air tube of a bicycle. Then I am photographed, and my portrait is put in the window, with the mention, 'Before treatment.' About half the air is then let out and another picture is taken of me. This one is also placed in the window with 'One month of treatment,' and finally I am photographed as I am, which represents 'After two months of treatment' !"

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, January 15th, 1905.

In the *Deutsche med. Zeitung* is a reference to an article by V. Erdberg, St. Petersburg, on

BOSSI'S DILATATION OF THE CERVIX.

with a report of a case. The patient was a primipara, æt. 23. The fetus lay in the first position. The head could only be reached through the anterior vaginal arch with difficulty, as it lay high above the pelvic inlet. The patient had an attack of eclampsia. After hooking the anterior lip of the uterus, the dilator was introduced and carefully dilated. The membrane at once ruptured. During the dilatation, which lasted thirty and a half minutes, the tenseness and dilatibility of the os were carefully noted. The writer could confirm the observation of Bossi that the dilatation provoked uterine pains. The pains became stronger and the head sunk deeper. After complete dilatation no tear could be detected with the finger, only the cervix hung in the vagina as a loose sac, as it was usually felt *post-partum*. There was no hæmorrhage. The head in the pelvic inlet was pressed into the middle of the pelvis by Hofmeier's method—forceps. The child was born asphyxiated, but resuscitated. There was no hæmorrhage on extraction. The fits, however, did not cease after the birth of the child, and a few hours later the patient died.

In the *Arch. f. Dermatol. u. Syph.*, Hr. Ludwig Wallsch has an article on

NON-GONORRHOËAL URETHRITIS.

The writer has seen nine cases, five of them medical men. They were characteristic. First, by the long stage of incubation (five to sixteen days) ; second, by the mildness of both objective and subjective symptoms (slight itching or burning in the fossa navicularis, a plug of secretion that was washed away by the pressure of passing urine, or a few with many pus threads in generally clear urine) ; third, by the very chronic course ; four, by the entire absence of gonococci ; and five, by the failure of the usual modes of treatment. The prognosis was, therefore, bad. Some of his cases had been watched for a year, in two without any improvement taking place. His cases had never had gonorrhœa or syphilis ; they showed no signs of tuberculosis, and suffered neither from phosphaturia nor oxaluria. No micro-organisms that would be considered specific were ever found, nor could any be cultivated. Two of the patients married ; one of them was the father of two children, and the wife had remained healthy. Besides the cases described, Bockhart and others had showed that there were still other forms of non-gonorrhœal urethritis. The author had seen three other cases in which gonococci were never found, but large quantities of micro-organisms of the group of pseudo-diphtheritic bacilli were present. These were distinguished from the former cases by the short stage of incubation (three to four days) and the circumstance that the symptoms were mild, and recovery took place quickly. Finally non-gonorrhœal urethritis might be set up by chemical or mechanical irritation of the urethra, of which class the writer had seen two cases.

Dr. A. Fraenkel has an article in the *Arch. f. exper. Path.* on

THE CUMULATIVE ACTION OF THE DIGITALIS BODIES. The investigation forming the basis of the paper confirms in essential matters the practical observations of physicians. It was determined that there was nothing to show that animals became accustomed to the action of the bodies. The symptom of accumulation develops equally ; with increasing doses the symptoms of intoxication developed rapidly. The substances examined, digitalinum, serum, digitotoxin, and strophanthus behaved much in the same way. Individuality played but a small part. In each of the drugs a certain daily dose could be determined that could be continued for weeks, but the increase of the dose, even when only small, led in all cases to toxic cumulation. There was a difference in the tendency to cumulation

in the different bodies. The interval between doses of digitoxin must be considerably greater than in the case of digitalin if symptoms of intoxication are to be avoided. Digitoxin, therefore, is more cumulative. In single doses of digitoxin the difference between active and fatal doses was so small that the author did not succeed in slowing the pulse by subsequent doses, without causing death. With strophanthus and digitalin, on the other hand, there was no difficulty with regard to that.

THE TREATMENT OF BASEDOW'S DISEASE BY ANTITHYROIDEIN (MOEBIUS).

The *Deutsch. med. Zeitung* has a report of a case by Dr. J. W. M. Indermans. A young lady, æt. 19, had suffered for some months from Basedow's (Grave's) disease, and had been treated by Moebius' thyroid serum. She finally took as much as sixty drops three times a day, with the result that she got much worse, so that she was admitted into hospital. On admission, there was severe congestion of the heart, extreme exophthalmos, enlargement of the neck, attacks of delirium, hallucinations, coprolalia, lowered temperature, pulse 120 to 130, with systolic murmurs. The symptoms receded under morphia injections. After a time treatment was begun again, but this time with antithyroidein in small doses—five drops thrice daily, and later ten drops. After about 10 c.c.m. of the serum had been taken an improvement was noticeable, there was distinct diminution of the exophthalmos. Græfe's and Stellwag's sign had disappeared and also the periods; pulse 100. The thyroid had become slightly smaller and less fluctuating. The dose was then raised to fifteen drops thrice daily, and in six days the exophthalmos had quite disappeared. In five days more, after the patient had taken a total of 50 c.c.m. of serum, she no longer showed any outward trace of the disease.

SUICIDE OF THE KAISER'S DENTIST.

The profession this week has been somewhat shocked at the sudden and unexpected death of Hofrath Dr. Alonzo Sylvester, at his residence in the Tiergarten. Dr. Sylvester started practice here nearly thirty years ago, and won a unique position among European dentists. He was not only Dentist to the Imperial Court, but also enjoyed the German Emperor's close friendship for many years. He was well known for his large-hearted hospitality and generous liberality in all cases where charity was needed, and his house was one of the favourite resorts of literary and artistic society. He was an American by birth, and had reached the age of 57, when he put an end to his life for no apparent reason, by blowing out his brains with a revolver.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, JANUARY 15th, 1905.

THE NEW DRUG LECITHIN.

At the Gesellschaft, Exner demonstrated two rats on which he had experimented with lecithin and the Röntgen rays. He injected an aqueous solution of lecithin subcutaneously, and then applied the rays to decompose the salt. Six days after the injection deep ulcers gradually formed. The solution of lecithin was next boiled in order to sterilise it thoroughly, but the ulcers still repeated after injections and application of the rays. If the injections were performed without the subsequent application of the rays no change took place in the tissues. From this he concludes that the lecithin is decomposed by the Röntgen rays, and that the new product formed is an irritant. It was resolved to continue the examination of this new product on the lines of Zdarek.

ARTICULAR TUBERCULOSIS.

Handek, in his criticism of Moorhof's therapy of articular tuberculosis, said this method applied to children between the age of one year and ten, as it was most essential to locate the site of the disease before treatment could be commenced. When the morbid

changes can be located to the distal side of the joint, Mosetig's operation can be early performed, and conserves the joint in a fairly good condition. As stated before, Mosetig recommends early cutting down on tuberculous centres, and then applying the Röntgen rays to destroy any hidden germs in the neighbourhood. Massage in all these cases is of no avail; on the other hand, Mosetig's treatment is rational.

HYPERNEPHROMA.

Albrecht demonstrated from drawings and preparations a case of hypernephroma. The case was a man, æt. 60, who was admitted to the surgical clinic, but has since died. About the beginning of last year a small tumour began to develop on the outer half of the left clavicle. Röntgen rays revealed an abscess arising from caries of the clavicle. In July, the patient was received at the polyclinic suffering from a fluctuating immovable tumour about the size of a hen's egg, covered with a normal cuticle over the site mentioned. Nothing abnormal was found in the urine. The operation was performed and a great deal of blood lost in its removal. At this time it was presumed, from the subsequent examination of the structure, that the tumour over the clavicle had taken its origin from a metastatic condition, probably hypernephrotic. After this diagnosis the patient was transferred in October to the surgical clinic with a tumour about the size of a child's head on the anterior side of the left shoulder, having a reddish-yellow colour and bleeding profusely when cut. The urine was then again carefully examined and the abdomen palpated, but no abnormal condition could be discovered. Shortly after the patient died.

At the *post-mortem* a hypernephroma about the size of a large nut was present on the medial margin of the left kidney, another about the size of a bean on the lower portion of the right suprarenal body, as well as a few small adenomata, about the size of peas on the left suprarenal body, with metastatic tubercles in the left lung. The pathognomonic triad of hypernephroma, which are pain, palpable tumour, and hæmaturia, were imperfectly present in this case. Pain, it is true, was present a short time, but no tumour cells could be found in the urinary sediment. The osseous metastasis was the first and only trustworthy symptom recognisable in sixteen cases coming to the clinic, only three others having a similar appearance. Israel's presumption that palpation alone can diagnose these cases is very doubtful. The readiest way of confirming hypernephronic metastasis in the bone is by operating, and when assured of its presence the particular kidney should be discovered and a radical cure attempted by early operation, as the duration of the disease encourages this form of treatment. Kapsammer said that catheterisation of the ureters was of very little value owing to the insignificant changes present in the kidneys. The diagnosis, therefore, would depend more on operative examination of the kidneys as Küster had recommended, by exposing both and splitting if required. He recorded one where he could discover nothing by catheterisation, but by splitting found a large cavern in the upper pole.

Albrecht replied that malignant tumours had the advantage in this form of testing. Splitting the kidney could be done in tuberculous conditions, but he said there was little need for it in hypernephromata, as these tumours usually localised themselves on the surface of the organ, causing very little functional disturbance.

Hochenegg thought that very little information could be obtained from catheterising the ureters. On the other hand, feeble patients may be dangerously reduced by operative measures owing to the hæmorrhagic tendency. According to his opinion, the renal parenchyma was almost always found to be in a normal condition, and therefore no functional changes could be expected. Frisch admitted that the renal changes were slight, but with the assistance of the phloridzin method the slightest deviation could be detected. This was surely an easier and a safer form of diagnosis than laying both kidneys bare in order to diagnose such small tumours.

The Operating Theatres.

TOTTENHAM HOSPITAL.

ABDOMINAL HYSTERECTOMY FOR FIBROSIS.—Dr. A. GILES operated on a single woman, *æt.* 27, who presented the following history: For five or six years she had suffered from menorrhagia for which she had been curetted four times in the Tottenham Hospital. After each operation there was a slight improvement for perhaps one or two months, and then the hæmorrhage would return as badly as ever. The effect of the hæmorrhages was that the patient was constantly anæmic and weak. For a week before the period was due her strength would pick up a bit, and with the onset of the period she again lost strength. On the last occasion when curetting was done, Dr. Giles noticed that the uterus was rather undersized, its cavity appeared contracted, and hardly any endometrium was removed with the curette. The diagnosis of fibrosis of the uterus was made at the time, and it then seemed evident that if menorrhagia should return, nothing short of hysterectomy would be of any avail. The respite after this curetting was not of many months' duration, for hæmorrhage soon returned as badly as ever, the periods lasting as long as sixteen or seventeen days. Hysterectomy was then proposed to her, the nature and results of the operation being fully explained. She expressed herself as only too willing to undergo any operation that offered a hope of permanent cure. On opening the abdomen, a small uterus presented; it was removed by the supra-vaginal method, a considerable portion of the cervix being taken away. The right ovary was large and cystic, and was consequently removed with its tube; the left appendages were healthy, and were allowed to remain. Dr. Giles said that this class of case was one that had not yet received a great deal of attention, although some isolated cases had been reported. He had himself met with several instances of this condition. The principal characteristics of it were menorrhagia that could not be controlled by drugs or curetting; a uterus which was small, or, at any rate, very little enlarged; negative results on curetting, by which he meant that little or nothing could be scraped away. It might be supposed that the hæmorrhage came only from the body of the uterus, but he had a case some years ago in which he did a supra-vaginal amputation without troubling much about the cervix, and hæmorrhage returned so profusely that he had to remove the cervix later on; this was why he took care to remove a good deal of the cervix in the present case. He had chosen the abdominal route rather than the vaginal for several reasons: in the first place, the patient was single, and a vaginal hysterectomy would have been attended with considerable difficulties of manipulation; in the second place, he thought it was an advantage to leave the lower part of the cervix to complete the top of the vagina; and, lastly, the abdominal operation gave a cleaner convalescence, as there was almost always suppuration after the vaginal operation, until the ligatures had come away.

The patient made a very satisfactory recovery, in fact, she appeared to have been much less disturbed in her general condition by this operation than by the previous curettings.

ITALIAN HOSPITAL.

OPERATION FOR REMOVAL OF THE UTERUS, THE

APPENDIX, AND THE RIGHT OVARY.—Mr. LENTHAL CHEATLE operated on a woman, *æt.* 32, whose symptoms were: great and increasing pain at her menstrual periods and hæmorrhage. The pain was rendering her life unbearable; it was situated in the hypogastric and right iliac regions. The uterus was increased three-quarters of an inch in length, as demonstrated by the sound, and on bimanual examination was found to be enlarged. The patient had been to many medical men, but the treatment advised and undergone had given no benefit, therefore she was advised to have a laparotomy performed, and to allow Mr. Cheatle to do what he thought necessary after examination of the parts affected. On opening the abdomen just to the left of the middle line, the uterus was found to be slightly enlarged, no fibroids could be felt; the right ovary was cystic, being nearly the size of a Tangerine orange; the appendix was curled on itself, its tip being adherent to its centre, and the whole adherent to the back of the cæcum. The appendix was removed by the ordinary method of forming a collar of peritoneum. This was done with a special instrument devised by Mr. Cheatle (and made for him by Meyer and Meltzer), which appeared to admirably answer the purpose of separating the peritoneal coat from the subjacent muscular coat. The right ovary was next taken away, and the uterus and cervix removed; the other ovary, which appeared normal, was left behind. The abdominal wall was sewn up in three layers, no drainage being employed. Mr. Cheatle said that as all previous treatments, which had included curetting of the uterus and a varied and prolonged medical course, had proved futile, the patient only having intervals of a week between the attacks of pain and metrorrhagia, during which times only she could attend to her household arrangements, he considered it was about time for an attempt to be made to remedy by surgical intervention such a deplorable state of affairs. Although the pain might have been appendicular, he thought the removal of the uterus was justified with regard to the fact that the attacks of pain were always accompanied by metrorrhagia. With reference to the instrument he had used to separate the peritoneal coat from the muscular coat, it resembled a gouge, the end of which is bevelled, and has a chiselled edge. The instrument is capable of separating the peritoneal coat from the muscular and pushing it back.

The patient made an uninterrupted recovery as far as her wound was concerned. During the first three weeks after operation, her mental condition, however, was peculiar. She imagined she heard voices, and was in a very excitable condition. These transient mental phases have been before noticed by Mr. Cheatle among his cases of hysterectomy. The patient eventually completely recovered.

London School of Tropical Medicine.

OF the thirty-seven students who attended the above school for the Session October-December, 1904; the following eighteen passed the examination at the end of the course, the first four "with distinction":—Drs. J. H. Cook, D. Alexander (Colonial Service), T. G. D. Cooper (Colonial Service), D. H. Ainslie.

Passed in order of merit:—Drs. W. A. Densham, H. N. H. Joynt (Colonial Service), G. H. L. Fitzwilliams, P. Phillips (Colonial service), J. Gillies; Miss Kathleen Dawson; Drs. D. A. Ashton (Colonial Service), J. C. Carr, R. Dane (Colonial Service), J. W. Gromitt (Colonial Service), C. H. D. Ralph (Colonial Service), A. C. Lorena (Colonial Service), F. L. Norris (Colonial Service), W. F. L. A. Holcroft (Colonial Service).

REGISTERED FOR TRANSMISSION ABROAD.

The Medical Press and Circular.

Published every Wednesday morning, Price 6d. Post free, 5jd.

ADVERTISEMENTS.

ONE INSERTION:—Whole Page, £5 0s. 0d.; Half Page, £2 10s. 0d.; Quarter Page, £1 6s. 0d.; One-eighth, 12s. 6d.

Considerable Reductions from the foregoing scale are made when an order is given for a series of insertions. Terms on application to the Publisher.

Small announcements of Practices, Assistantcies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

SUBSCRIPTIONS.

Subscriptions may commence at any period of the year. If paid in advance the cost is only 21s. per annum, post free. An edition is printed on thin plate paper for foreign and Colonial subscribers at 21s. per annum, post free, if paid in advance, or 28s. 6d. credit rate.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JANUARY 18, 1905.

THE HOSPITAL FUNDS, HOSPITAL POLICY AND SCOTCH QUALIFICATIONS.

THE need of some definite policy and declaration of principles in those otherwise most excellent institutions, the London Hospital Sunday and the King Edward's Funds, is abundantly proved by the way in which the present series of articles is being treated. Sir Henry Burdett has come forward, in the pages of the *Hospital*, as the champion and exponent of those Funds. His methods are neither particularly enlightening nor convincing. He confines himself to a triumphant exposure of non-essential errors of detail, while he leaves vital questions of principle unanswered. In proof of this proposition, in the last issue of the *Hospital*, that of January 14th, 1905, he states that the article in our last issue contained two misstatements: (1) That the Council of the Sunday Fund contains fifty clerical or lay members; (2) that the Fund has no representatives of the small hospitals upon either the Council or the Distribution Committees. Dealing with these points in turn, our first sentence should clearly have read "clerical and fifty lay members." But does the detection of this misprint justify Sir Henry Burdett in ignoring our contention that the making of grants was practically in the hands of the Distribution Committee, a small body of whom several leading members are avowedly antagonistic to the small hospitals? As to (2) our article said, "We fail to find on the Sunday Fund Council the name of a single representative of a small hospital." Sir Henry Burdett has discovered Mr. J. R. Cooper, chairman of the amalgamated Royal and Orthopædic Hospitals, and the two honorary secretaries of the Fund, Mr. Martin, who represents the St. Mark's Hospital for Fistula,

and Mr. Gilliat, the Royal Chest Hospital. This statement we accept, but can Sir Henry Burdett imagine that the presence of these three gentlemen upsets our contention that the small hospitals, speaking generally, are not adequately represented on the Councils either of the Sunday or of the King's Funds, for both were included in our criticism? Other vital questions in our article of the 11th are ignored by Sir Henry Burdett. We wished to learn if the whole facts of the sale of site and of amalgamation were in the possession of the committee of distribution of the Sunday Fund before they advised amalgamation, which, of course, connoted sale of site. No answer is given to this pertinent inquiry, or to the further question of how minutes are kept of such information, if, indeed, we may presume the committee had any laid before them; nor whether, as City men, past or present, Sir Henry Burdett and Sir Sydney Waterlow had perfect confidence in Mr. Harry Marks' financial policy with regard to the hospital. No answer, again, is given as to whether the Sunday and the King Edward's Funds had considered the objections of the minority who resisted Mr. Marks in his scheme to sell the site of the Orthopædic Hospital. These objections were urged by the *Lancet* and by ourselves, but have never been adequately met anywhere. It appears we were in error in saying the King's Fund pressed the sale of the site of the Royal Ophthalmic (Moorfields) Hospital, but it is none the less true that they are now paying enormous grants to help the bankruptcy arising from that sale of site. The Sunday Fund we believe, approved that sale, and are also helping to pay the piper. With that object-lesson before them we should have thought they would have afterwards exercised the greatest caution in advocating the sale of valuable sites possessed by hospitals, whether in pursuit of a policy of amalgamation or otherwise. It may well be asked why amalgamation was not pressed upon the Moorfields Eye Hospital as a condition of grants. There are far more eye hospitals in London than orthopædic. The fact is the more this question is discussed the more apparent does the absence of any definite settled principles of administration of the hospital funds become apparent. There is another point in connection with the amalgamation of the orthopædic hospitals to which we feel it desirable to call emphatic public attention. We understand, on good authority, that the National Orthopædic made it a condition of amalgamation that no surgeon without an English qualification should be permitted to join the fixed staff. That offensive condition was aimed at gentlemen with Scotch qualifications, and it was modified to the extent that one of the Royal Orthopædic surgeons having a Scotch qualification was permitted to join the amalgamated staff on the understanding that his term of office would be shortly terminated. The Sunday and King Edward's Funds approve the amalgamation. Do they know that in doing so they are playing into the hands of gentlemen

who are seeking to protect their professional position by the exercise of a grossly unfair advantage? The Funds are now urging the City Orthopædic Hospital to amalgamate. Do they know that the exclusion of non-English qualifications would at once dismiss the senior surgeon? The truth is that it is impossible for the Funds, without the fullest inquiry, to appreciate the consequences of enforcing this, that, or the other policy upon small hospitals. By all means let us have a central controlling power, but let that power be representative of all interests; let it be well informed, and let it act only on well-considered and clearly-defined principles. In no other way can the lasting confidence of the medical profession and of the public be secured. In the course of further articles we shall hope to provide further material worthy of the earnest consideration of the administration of the Funds. We are encouraged by the attitude of the Prince of Wales towards inquiry and economical hospital administration, and still more so by the well-known impartiality and sense of justice that have secured the admiration of Englishmen for his father, King Edward. There is no need for importing any heat into the discussion, and surely the Funds should be prepared to welcome criticism that is not conceived in any unfriendly spirit. Why, for instance, should not a small judicial committee be appointed to examine into the whole of the circumstances attending the sale of site and the amalgamation of the Royal Orthopædic Hospital? As things stand, the arguments of those who opposed that scheme have never been fairly heard, and certainly have never been satisfactorily answered. The Funds that can assume so great a responsibility as that of urging the sale of a freehold endowment site may reasonably take the smaller step of appointing a committee of inquiry.

SALINE INJECTIONS.

In no part of the field of physiology have recent researches been more rich in practical results than where the blood is concerned. Our knowledge of the functions of the leucocytes is of entirely modern date, and is intimately bound up with the physiology of defence against bacterial and toxic attacks. It is only a few years since plasma was regarded merely as the medium by which the red corpuscles were swept along with their load of oxygen for the tissues, by which food was carried to the parts and waste products were returned. Nowadays, however, it is known that these are but a few of several functions, and that the plasma is a fluid of bewildering complexity, whose intimate chemical constitution we are bound to discover. It was, however, somewhat prior to this discovery of the complexity of the plasma, and the consequent importance of maintaining its chemical equilibrium undisturbed, that the use of saline injections was discovered. In cases of shock, sudden hæmorrhage, collapse, and generally where the circulation needs support, as well as for the purpose of diluting poisons

already in the blood, every surgeon and physician has come to rely on the injection of saline fluid. He has not been taught, however, that it is of prime importance that this saline fluid should, as far as possible, resemble the plasma in composition. The solution commonly used is one of sodium chloride of 0·6 or 0·7 per cent., a percentage originally adopted, not because it was isotonic with human blood, but because physiologists found it the most advantageous in experiments on the frog. It may be stated that a solution of 0·9 per cent. would be far more suitable for clinical purposes. If the solution be either too weak or too strong it seriously injures the red cells of the blood, and doubtless also all other cells which it reaches. A variation of ·1 or ·2 per cent. from the physiological normal may cause damage, and with a ·5 per cent. solution of sodium chloride the corpuscles are actually destroyed. Not only, however, is it necessary that the sodium chloride solution shall be of accurate composition, but it is of advantage that certain other substances should be present. Thus, Dr. Ringer has shown the advisability of adding a small quantity of calcium to the salt solution, and more recently he and others have shown that potassium should also be present. In addition to preventing direct injurious effects on the cells of the blood, it has been shown that the presence of calcium prevents the occurrence of glycosuria, a phenomenon which not uncommonly follows a saline injection. It behoves surgeons and physicians, then, to exert the greatest care that the saline injections they employ are, in the strictest sense, "physiological"; a slight variation may mean the difference between the health and disease of "the blood, which is the life."

RURAL HOUSING.

THE unusual, we might almost say dramatic, incident of one of His Majesty's judges of the High Court being summoned to appear before a bench of country magistrates sitting in petty sessions would at any time arrest the attention of the most phlegmatic citizen. And the point at issue between Sir William Grantham and his prosecutors, the Chailey Rural District Council, is well worth all the attention that will be directed to it. It would be difficult to exaggerate the importance of the question if looked at in its ultimate bearings, although the actual dispute would appear from the line taken by Sir William Grantham's counsel to have been considerably over-laid with personalities. This question in effect is: Is it possible in England to construct a cheap, comfortable, sanitary cottage for the agricultural labourer? On the answer to that question depends to a great extent the retention of the labouring population on the soil, and such retention means the preservation of the springs whence are derived the best types of British physique and vigour. One hears nowadays on all sides complaints as to the overcrowding of towns, and the consequent mental and physical degeneration of the population, and although it has been

shown that these complaints, like many others, are exaggerated, still there is no denying the fact that the health of urban is not, and cannot be, as good as that of rural populations, and after several generations the adverse influences of town-life are bound to show themselves in the frame and constitution of the people. There is also widespread and natural alarm at the increase of insanity of late years. In London, since the County Council took over the administration of the asylums in 1889, though the general population has only increased by $12\frac{1}{2}$ per cent., the insane poor, who have to be provided for, number half as many again as they did fifteen years ago, and each year their ranks are swelled in proportion. It may not be fair to attribute this increase entirely to the conditions of town-life, but there can be no doubt that those conditions are responsible to a greater or less extent. Slums have never yet produced the finest type of man, and if the country districts are to be depleted of their inhabitants, the outlook for the race in the long run will be a gloomy one. Now, among economists, fiscal and otherwise, and hygienists who have studied the question, one of the chief problems in the retention of the agriculturist in his native haunts is the possibility of giving him a home at a rental which he is able to pay, and which at the same time will remunerate the landowner or farmer who has sunk his capital in its erection. A cottage of sorts can, of course, be built, but owing to the exertions of hygienists the sanitary requirements of cottages have been fixed at a level that makes a cheap cottage which accords with the standards laid down by the Building Acts, and the by-laws made under them, very difficult to provide. Far be it from us to minimise the importance of such sanitary requirements; an unhealthy cottage is only a shade better than no cottage at all, and a robust race would deteriorate if forced to live in dark, damp houses furnished with improper conveniences, and supplied with contaminated water. On the other hand landowners cannot be expected to build cottages which do not pay them as an investment, and agricultural labourers cannot pay rents that swallow up half their scanty incomes. The problem of the cheap cottage is, we repeat, one of national moment, and we note with satisfaction that the proprietors of the *County Gentleman* are making a public-spirited endeavour to solve it by giving substantial prizes for the best cheap cottage erected at the exhibition they propose to hold. Intrinsically difficult as the question is, it is complicated still more by the by-laws of the local authorities, and by the spirit in which these by-laws are administered, at least in some parts of the country. Urban authorities animated by no other desire than that of promoting the public good find themselves constantly thwarted and hampered by the conditions laid down by the Local Government Board with regard to the financial arrangements for the carrying out of their housing schemes, and private gentlemen are liable to similar annoyance from the

authorities they come in contact with. Sir William Grantham, apart from his high office, is well known as a squire of the best type, who is deeply concerned for the welfare of the workers on his estate and who wishes to act up to the full measure of his responsibilities. One of the economies he tried to introduce into cottage-building was that of preparing his own plans—a task he was to some extent qualified by his previous legal experience—but the resulting plans did not commend themselves to the critical judgment of the local surveyor and the Rural Council of Chailey. Consequently, instead of trying to aid him in his well-intentioned, if somewhat amateur schemes, after a good deal of to-and-fro correspondence, a summons was issued for Sir William to attend before the magistrates. As the bench did not arrive at a clear decision and further steps are hinted at, we refrain from commenting on the technicalities of the case, but we cannot help remarking that all possible attempts to make rural housing cheap as well as sanitary deserve and must command the sympathetic interest of all who desire to maintain and improve the health and physique of the nation.

Notes on Current Topics.

Coroner and Infantile Mortality.

THE cheapness with which infantile life is held in some countries is rightly regarded with horror by Englishmen. Nevertheless, it cannot be denied that there still exists in many quarters a lamentable indifference on the part of the parents to the safety of their offspring. Overlaying is an evil which, though happily becoming less, is nevertheless rife, as may be seen by the fact that in 1902 1,600 inquests were held in England and Wales upon babies suffocated in bed. In a recent account of an inquest held upon the body of an infant which had thus succumbed, Dr. F. J. Waldo, Coroner for the City of London, is reported to have said that he did not believe that intemperance of the parents was the cause of these deaths save in a few instances. This may or may not be the case, but the coroner's statement has evoked considerable criticism, and Canon Horsley is one of the first in the field to challenge his remarks. We presume the coroner's original reference was based upon inquiries made by his officer, the only available investigator in such cases. The reverend gentleman takes exception to the word "generally" employed by the coroner, who stated that he "generally" made careful inquiries into the circumstances attending the death of overlain infants. The evidence of the Coroner for Newcastle-on-Tyne is quoted against the statements of Dr. Waldo, to the effect that deaths from suffocation invariably occur between Saturday night and Sunday morning, just at the time when the parents are apt to go to bed under the influence of drink, the workmen having received their wages at mid-day on the Saturday. During the festivities of Christmas a larger proportion of deaths is said to occur from this cause.

and Canon Horsley finds it difficult not to believe that the two events stand in the nature of cause and effect. Intemperance is certainly not the only cause of this form of infantile mortality, though it has to be reckoned with. The obvious remedy for this state of affairs is the provision in every home of separate cots for babes, a provision that, by the way, is compulsory in Germany.

"Following the Midwife."

THE most unenviable notoriety that a practitioner can get is that of "following a midwife"—a term which in poor districts conveys a low estimate of a doctor's status. Moreover, when a midwife is "followed" it is done generally to relieve her of the onus of a bad case which has often been left too long untreated; and as the midwife was originally engaged from motives of economy, the prospect of the doctor getting a fee for his trouble is very remote. Some practitioners make it a rule not to go to such cases at all, or only when their fee is tendered, and it is easy only to those who know little of the conditions to utter any word of criticism on such an attitude. At an inquest on a newly-born child at Wood Green last week the midwife is reported to have said that a doctor was called in, but that, seeing no signs of a fee, he refused to have anything to do with the case. The Coroner, in his remarks, said that if the woman had been properly attended to the child's life might have been saved, and that happily ninety-nine doctors out of a hundred would give their services willingly whether they saw any signs of a fee or not. The lesson to be drawn from the circumstances is the manifest one that it is dangerous to allow unqualified persons to conduct confinements without skilled supervision; but this does not seem to have struck the listeners, nor that the doctor's attitude is about the only one by which a man can prevent himself from being landed in an invidious position in which it is not right or fair that he should be placed.

Vaccination and Red Light.

THE controversy started by Finsen's announcement of the abortive influence of red light on the development of the small-pox papule has yet to be settled finally. Ricketts and Byers, in London, have pronounced definitely against any tangible effect being produced, whilst Nash and others are inclined to believe that there is some virtue in the method. It would be interesting if some medical officers with the requisite facilities would carry out a series of experiments on the effect of red light on vaccinia. If the patients could be kept in a ward lighted entirely by red glass from the time of vaccination to the time of maturation of the resulting lesion, important information might be forthcoming as to the probable effect of the treatment in modified small-pox when early placed in similar surroundings. In the meantime we notice that Knöpfelmacher and Schein^(a) have been making

trials of a similar procedure in Austria. Eighteen consecutive children were vaccinated by them on one arm in a red-lighted chamber, the wound being afterwards covered with a red bandage, whilst the other arm was vaccinated and exposed to daylight. In thirteen other children vaccinations of both arms were performed in daylight, one arm being subsequently bandaged with red material the other with calico. In the former series they thought the arms vaccinated in red light and covered with red bandages showed a slight delay in the development of the pustules, whilst in the latter series no difference at all was perceptible. Although it does not necessarily follow that because red light is of no use in vaccinia, it is therefore of no use in small-pox, still, considering the strong parallelism between the two diseases, the evidence thus obtained is significant.

Medical Men and Lay Papers.

WE regret to see in the *Nineteenth Century* for January an article entitled "The Cause and Prevention of Appendicitis from a Physician's Point of View," under the signature of Joseph Kidd, M.D. It always has been, and still is, regarded as bad form for medical men to write on purely professional subjects in popular journals. The reasons for this are sufficiently obvious. An editor, however able, who is not possessed of technical knowledge cannot judge of the value of a medical article—and consequently fantastic rubbish arranged in plausible garb is quite as likely to be inserted as good matter, and in our experience the former is generally the case. Then, too, lay readers are apt to form the opinion that Smith, M.D., or Jones, F.R.C.S., who finds his way into print in the columns of their favourite magazine would not have been allowed the honour unless he had been possessed of special qualifications for the task. Here, again, our experience is totally opposed to the idea of the best man being asked to write. Moreover, articles of the class we are dealing with are almost invariably written with an air of authority that conveys the impression that the writer's statements are the authoritative expression of accepted medical opinion, whereas when they rise above the level of trivial banalities their statements are generally pretty wide of the truth. There is no lack of medical journals, weekly and monthly, to which contributions worthy of professional attention can be sent, and in whose columns criticism from qualified persons can strengthen or diminish a writer's theories, as the case may be. It is, then, in the highest degree undesirable that communications like Dr. Kidd's should be sent to lay magazines, especially when the writer's name is appended. The particular article in question is hardly worthy of notice either from the point of view of subject matter or style, yet it has received wide quotation in the sensation-loving press organs. We are far from deprecating the proper dissemination of hygienic knowledge on public questions—such as the effects of bad housing, impure water, and improper

(a) *Wien, klin. Wochen.*, 1904, Nr. 40, p. 1069.

education on the health of the nation—in standard magazines; indeed, we should like to see medical men possessed of the proper qualifications to speak with authority using their opportunities more freely in this direction. But all such articles must be obviously dictated by a transparent desire for the public welfare, and entirely free from any suspicion of faddism or self-seeking.

Concealment of Trachoma.

AN ingenious and interesting device adopted by immigrants to America to evade the inspection officers of the Public Health Service has lately been brought to light. The diseased alien does not receive the same open-hearted welcome in the States that he does on arriving at Tilbury, and strict surveillance is exercised on the steerage passengers of the trans-Atlantic liners to prevent any that are suffering from communicable diseases being allowed to land. One of the diseases which are frequent causes of rejection is trachoma, and the rebuffed immigrants have evidently been laying their heads together to baffle their foe, the port doctor. The story of their discomfiture is told in the "Reports of the Public Health and Marine Hospital Service." The health officers had for some time been noticing that certain passengers whose appearance suggested trachoma presented, on examination, no sign of the disease, but instead a blanched condition of the conjunctival mucous membrane. After they had noticed this several times they set some of the cases aside for re-examination, and when the lids were everted again after an interval of an hour or two they discovered, to their surprise, that the previously pale conjunctiva presented unmistakable signs of early trachoma. The explanation that lay at the bottom of this unusual phenomenon was revealed by closely watching a party of immigrants, who were waiting for examination. A number of these were seen to slink behind a convenient enclosure, and there were observed to be putting drops of some fluid into each other's eyes. This fluid was found afterwards to be adrenalin chloride solution, which has the power apparently of concealing the granular appearance of the lids in early trachoma by bringing about general blanching of the mucous membrane—a state of things that lasts for half an hour or so after the instillation. How these passengers came by this curious piece of pharmacological information does not appear, but the trick has evidently been in vogue for some time, and we believe it is a novel item in the science of malingering.

A Strange Medical Career.

FROM Mr. W. H. Wilkins' latest work, "A Queen of Tears," the current number of the *Practitioner* makes several interesting extracts illustrative of the career of Struensee, an obscure physician of Altona, who rose to be virtual sovereign of Denmark. Born in 1737, the son of a Lutheran minister, and educated in medicine at Halle, he was medical officer of Altona in 1768, and thinking of seeking a remedy in the East

Indies for the fortunes broken by his extravagant and sensual mode of life, he was by chance recommended for the post of travelling physician to King Christian VII. of Denmark. He was so successful in ingratiating himself at Court that a year later, when the girl Queen, who was on bad terms with her husband, fell ill, she became his patient. This lady, then seventeen years of age, was sister of George III. of England. Struensee now devoted all his energies to obtaining power over her, and by his help she soon regained her influence over the half imbecile King, and, being popular with the people, her power knew no check. In fact, Struensee, Court physician and lover of the Queen, was for the time supreme in Denmark. He attempted startling reforms—abolition of serfdom, reform of the marriage laws, lighting of Copenhagen, liberty of the press—in fact, he tried to carry into effect the political ideals of the French constitution-spinners. This absolute power went on for two years, when a sudden movement of the old Court Party, led by the Queen Dowager, and backed by the fickle opinion of the people, threw poor Queen Matilda into prison and hurried the adventurer to his death. But, speedy as was his punishment, it was not fast enough to prevent his rounding on his mistress, and, in a blackguardly confession, exposing her pitiful story. She, poor victim of his insatiable ambition, died three years later, divorced and disgraced, at the age of twenty-three. Of his short-lived greatness only one memorial remains—the Foundling Hospital at Copenhagen.

Misleading Statistics.

THERE IS, perhaps, no subject in which the untrained mind is more apt to go astray than statistics. One constantly sees a quite honest man, by a perfectly unintentional misuse of figures, arrive at conclusions which will not bear for a moment the examination of a skilled statistician. One of the latter class, indeed, Professor Karl Pearson, has recently pointed out the crying need there is for a more exact treatment of statistics in medical science. And though, perhaps, as an expert Professor Pearson is inclined to see too large the ignorance of non-experts, yet, in the demand for more exactness and greater care in the use of figures, we cordially agree with him. A good example of what we mean by misleading statistics is the set of figures put before the General Medical Council each year showing the numbers of successful and unsuccessful candidates at the different Service examinations, classified according to the respective qualifications they hold. Now, if this return has any use whatever it is as throwing what a contemporary calls "a sidelight upon the educational methods and curricula in force in different parts of the United Kingdom." That is to say, it is to be regarded as furnishing some sort of criterion of the education furnished by different licensing bodies, those which supply the highest percentage of successful candidates being considered as furnishing the best education. Many criticisms might be urged against such a

view, which, nevertheless, is probably in the minds of most people when they read the returns, but we mention only one obvious fallacy which vitiates the whole conclusion. This is that there are no data to show whether the candidates from each body are in any way representative of that body. It may be that only the mediocre men from one school care to present themselves, the better men choosing other careers. From another school the good men may present themselves in large number, no other career being open to them. In such a case the percentages of success are no measure of anything except of the candidates themselves, and we know that in regard to some of the schools concerned this very condition holds.

Electricity and Rheumatism.

THERE has been something of a boom during the last year or two in that form of entertainment which performs the double function of gratifying pleasure-seeking audiences and of demonstrating the healing gifts of the entertainer. The individuals who make a living by this means are queer combinations of the showman, the conjuror and the quack; but they have always sufficient self-assurance to exercise their arts to the greatest advantage, and generally manage to hypnotise their audiences as effectively as they electrify their patients. One of the most successful of the species is "Professor" Richard, M.E., who is now favouring Hastings with exhibitions of his skill. From the reports that reach us he seems to have been highly successful, both in drawing audiences and "curing" patients. Paralysis rapidly improves under a few minutes' application of electricity, and rheumatism permanently disappears when the affected part is manipulated by the Professor's hands. Sufferers from deafness, bad eyesight, neuralgia, and "almost" any other complaint are invited to subject themselves to the influence of the vital fluid with which the Professor is charged; and though no patients suffering from these maladies seem yet to have come up for treatment, we have no doubt that they will be reported as cured or permanently relieved when they do. The local press contains graphic accounts of these magical exhibitions and the humorous interludes with which the tedium of watching sufferers being cured is relieved, whilst Richard is extolled as a benefactor to the human race. It speaks little for the reflective faculties of people who think thus that they fail to take into account the itinerant habits of such professors, for if the treatment was really of any avail surely the wonderful curers would rapidly amass large fortunes by taking central offices and carrying on a permanent business: As it is, having obtained a certain notoriety by judicious use of the puff in its various aspects, and secured a certain reward for their efforts, they move on before a reaction in popular feeling has had time to set in. There is a serious side to demonstrations of this sort which hardly calls for comment to medical readers. If the Professor or any of his kidney should happen to inflict any injury when using

powerful electrical instruments on those persons who are silly enough to submit to their ministrations, there might be awkward legal complications. But in such a case one could trust the Professor to look after himself.

The Ante-Partum Insertion of Perineal Sutures.

WE publish in the present number an interesting communication by Dr. Laphorn Smith, a well-known Canadian gynaecologist, in which he advocates the insertion of perineal sutures before the birth of the foetus, in anticipation of the occurrence of laceration. The practice which he advocates is a novel one, and, in so far as it draws attention to the usual occurrence of perineal lacerations in almost every primipara, and to the necessity of immediately suturing them, his communication possesses a high value. Further, his method is harmless, and in many cases we can quite believe that the sutures, when tied, will cause accurate coaptation of the parts. It is not, however, an ideal procedure, nor one that is likely to attain wide acceptance. We are entirely at one with Dr. Smith in his agreement with Emmet that one "might as well sew up her drawers as sew the skin of the perineum," and we therefore prefer to see and know the entire extent of the laceration before commencing to suture it. Superficial lacerations of the perineum involving only the anterior half of the perineal body are easy to suture under any circumstances. They can be sutured in the dark by the sense of touch alone, if the medical attendant is so foolish as to try to do so, and, even if the sutures are not passed with absolute accuracy, union will result provided that infection of the wound does not occur. The lacerations that extend up the vagina, on the other hand, are at once most difficult to suture correctly and most serious in their after-consequences if union is not obtained, and, in their case, we do believe that accurate coaptation will be obtained by anticipatory suturing. Rather, we should prefer to advise the medical man to postpone the suture of these cases, when they occur at night in a badly lighted room, until the following day. The posterior vaginal wall can be then exposed, the vaginal rent sutured from the vagina, and the perineal body sutured in the usual manner by sutures passed from the skin surface.

Ankylostomiasis in England.

IN view of the infection of some of the Cornish tin-miners by the ankylostoma, it is of importance to take every possible precaution to prevent the spread of this parasite. Should it gain a wider distribution, and, more particularly, should it obtain a permanent footing in the coal-mines of the country, a serious danger to the mining industry of England will result. An object-lesson of what may be expected in such a case is to be got by observation of the actual condition of affairs in the mining districts of Westphalia and Hungary. Within the last two years it is stated that the mine-owners of Westphalia have spent £100,000

in the struggle against ankylostomiasis. If this sum is spent in order to get rid of the disease, an incomparably greater amount would be required to represent the economic loss due to it. A few years ago in some of the Hungarian mines no less than 90 per cent. of the workers suffered from ankylostomiasis, but nowadays, thanks to rigorous hygienic measures, the percentage has run down to thirty. Fortunately, the necessary precautions are not difficult to follow. In England no foreign miners or miners from infected districts should be allowed to work until they have undergone a thorough medical inspection, with expert examination of the blood and fæces. Defæcation in the pits must, moreover, be absolutely forbidden, unless where proper sanitary provision has been made. If these simple rules are loyally followed out, there is little danger of any serious ankylostomal infection.

Medical Phraseology.

THE cheap sneers at medical phraseology, indulged in by the recognised wit of the metropolitan Bench of magistrates—Mr. Plowden—are, to say the least, uncalled for and undignified. Mr. Plowden, as a member of the Bar, must be fully aware that most legal terms are no more understandable to lay persons than are those which belong to medicine. In a recent case before him he angled for applause in his court by attempting to throw ridicule upon the term "epistaxis" used by a practitioner. Instead of sneering at a medical term which he did not understand, we venture to suggest, having regard to the phraseology of his own profession, that it would have been more dignified on his part to have asked for an explanation, more especially as he must know that there are many terms used in medicine, which, in the vernacular would sound both rude and objectionable.

Diagnosis at Infectious Hospitals.

IN the reports issued by infectious hospitals a note is often made of errors of diagnosis made by general practitioners with regard to supposed diphtheria, small-pox, scarlet fever and so on. The converse case, that of mistakes made by the hospital medical staff, is naturally enough not officially mentioned. That such cases must now and then occur is obvious enough if we consider the difficulty, or even impossibility, of diagnosis in early and anomalous stages of many general infections. Speaking broadly, it is less excusable to make such error in the later or hospital stages than in the early and often more or less masked conditions that come under notice in general practice. Moreover, there is no appeal against the decision of the medical superintendent at the fever hospital. The only time that he is likely to be called upon to justify his opinion is when an inquest takes place. The superintendent of a London suburban small-pox hospital last week had to admit his error in refusing admission to a patient whom he took to be suffering from some form of skin disease

and not from small-pox. The man died soon after from hæmorrhagic small-pox. Some errors, humanly speaking, must occur under any system. It is rarely, however, that a careful examination by a skilled observer could fail to detect the presence of small-pox. In any case the sick man might have been kept in a probation ward. Here we find the opinion of the general practitioner of more value than that of the expert. The moral is obvious.

Revivalism and Mental Disease.

THE report that ten patients have been admitted into the Denbighshire County Asylum as a result of the recent revival in Wales is not, perhaps, altogether surprising. The causes which upset the mental equilibrium of neurotic and unstable individuals are sometimes so trivial that it is hardly to be wondered at that this new excitement has turned the brains of the unduly impressionable. Religious excitement is regarded by the general public as one of the most frequent causes of insanity, and, indeed, many text-books of mental diseases devote no small space to the discussion of the so-called "religious mania." As a matter of fact, most asylum physicians have found that religious disturbances are often more a symptom than a cause of insanity. Ideas of extreme unworthiness, of being irreparably lost, or of having committed "the unpardonable sin" are sometimes dominant features of the mental state of melancholics of a certain type. As Dr. G. H. Savage has aptly remarked, religion more often colours than produces insanity. It is youth and middle age that are chiefly affected by outbreaks of religious excitement. The appeal to the higher emotions is often irresistible to such, and the more unstable ones are not unlikely to become mentally unhinged. It must be admitted, however, that the proportion of those who drift into asylums as an outcome of an extensive religious revival is extremely small compared with the vast numbers that attend the meetings. All sorts and conditions of men, embracing almost every creed, are attracted, to some extent, by the outward exhibition of revivalistic fervour, and they are frequently induced, against their will, to listen to the preacher. A thoughtful observer, regarding such a gathering from a psychological aspect, is struck by the immense power possessed by spiritual forces over the material, and, perchance, the critic himself, wholly disarmed by the simple Gospel narrative, lays open, it may be for the first time, the innermost recesses of his being to the compelling influences of the Divine.

Our Foreign Correspondents' Column.

FOR many years one of the leading features of THE MEDICAL PRESS AND CIRCULAR has been the weekly letters from foreign medical correspondents. Those who peruse those communications week by week need not be told that they often contain scientific information of a valuable character.

In many instances the fruits of progress in other countries, when conveyed through the medium of an intelligent correspondent, throw a fresh light on home work, and furnish pabulum of a solid yet stimulating and refreshing kind. On page 61 of our present issue will be found, for instance, an interesting note on the rare condition of hydronephroma. A recognition of the salient points of the metastatic growths therein mentioned may afford a key to otherwise obscure processes. The full indexing of these subjects for future reference is not an easy matter. Readers, however, who keep an eye on our foreign correspondence will most likely find themselves now and then repaid by the discovery of information upon some point in which they are specially interested, for the range of subjects dealt with is of a most comprehensive nature.

Nasal Affections and Children's Diseases.

THE clinical examination of a sick child is generally fraught with difficulty that does not exist in the case of an adult. Obviously, the younger the child, the more tact and patience are needed during the physical investigation. The orifices of the body frequently furnish clues to diagnosis from mere inspection alone. In the case of the nose, such symptoms as sniffing, epistaxis or rhinorrhœa are sufficiently obvious to attract attention, and, moreover, parents will generally only be too ready to supply information upon these points. The habit of "picking the nose" is often made much of by the friends of the patient, and this sign is popularly supposed to be diagnostic of intestinal worms. The presence of intra-nasal disease itself, giving rise to local irritation, is apt to be overlooked under such circumstances, and the case is airily dismissed with a santonin powder. At the next visit, the nasal organ is still the centre of attention when the physician ventures, perhaps, to examine the nasal fossæ with a speculum. That he will frequently be successful in discovering some abnormality of the parts is the opinion of Dr. Louis J. Lautenbach, (a) of Philadelphia, who read a paper upon the need for a more careful study of the nasal fossæ in sick children before the annual meeting of the American Medical Association. It is contended that many infantile disorders are directly or indirectly produced through chronic affections of this part of the respiratory tract. Thus, disturbances of digestion and pharyngitis may arise from chronic obstruction of the post-nasal space or from a neglected atrophic rhinitis. The association of deafness with naso-pharyngeal catarrh is, of course, well recognised. Chronic bronchitis has frequently been relieved by a thorough overhauling of the nasal passages, and Dr. Lautenbach has drawn attention, two or three years ago, to the connection between nasal disease and an unequal curvature of the cornea, causing astigmatism. Foreign bodies are not infrequently discovered in the nostrils of children.

PERSONAL.

PRINCESS CHRISTIAN has consented to lay the foundation stone of a West Wales Consumption Sanatorium at Llanyfytter. The employées at the Pembroke Dockyard will probably support two of the twenty beds.

AMONG the passengers on board the SS. *Sobo*, which sailed for West Africa on the 31st ult., was Dr. R. E. M'Connell, member of the Liverpool School of Tropical Medicine, this being the fourteenth voyage for research purposes.

AT a joint meeting of the Cardiff Medical Society, on January 4th, it was decided to invite subscriptions towards the expenses incurred by Dr. Griffiths in defending the action brought against him by a patient. Dr. A. P. Fiddian, treasurer of the society, will receive any subscription sent.

To endow a bed in memory of his late wife, Sir Robert Harvey, of Trenowth, has given £1,000 to the Cornwall Infirmary, Truro.

AN illuminated address has been presented to Dr. T. J. Jefferson, J.P., by the Maxwell Lodge Oddfellows as a mark of gratitude for his services to them during the past forty years.

PROFESSOR NOTHNAGEL, of Vienna, Professor Pavlov of St. Petersburg, and Professor Marchiafava, of Rome are among the recently elected foreign members of the Royal Medical and Chirurgical Society.

THE Inaugural Dinner of the Association of Medical Diplomates of Scotland will take place at the Trocadero Restaurant, London, on February 14th. Tickets half a guinea each, may be obtained of the Hon. Sec. Dr. David Walsh, 18A, Hanover Street, London, W.

THE fire which took place recently at the Buck County Asylum was first noticed by Nurse Mary Kinsella, who was returning from night duty. To her presence of mind, aided by the Matron, Miss Millard, the prevention of a great disaster was due.

A RESIDENT of Esher, having offered £100 to the Royal Waterloo Hospital if four others would do the same, has been met by Sir Edgar Vincent with another £100.

It is announced that Dr. W. Heck, of Rheydt, Rhineland, is betrothed to Fraulein Bertha Krupp, of Essen, who is reputed to be the wealthiest heiress in Germany.

AT the quarterly meeting of the Council of the Royal College of Surgeons of England last week, a report was received regarding an offer made by Mrs. Macloghlin, of Southport, to found scholarships in memory of her husband, the late Mr. E. Percy P. Macloghlin, M.R.C.S., formerly in practice at Wigan, which was gratefully accepted. It is proposed in five years from his death, to give to the Royal College of Surgeons of England a sum of £10,000 for endowing these scholarships.

DR. H. TIMBRELL BULSTRODE has been appointed to represent the English College of Surgeons at the Conference on school hygiene to be held in London next month, under the auspices of the Royal Sanitary Institute.

DR. E. W. WHITE, who has just retired from the post of medical superintendent of the City of London Asylum, which he held for nearly twenty years, has been presented by the Visiting Committee with a gift of silver and an illuminated address. The presentation was made by Sir George W. Truscott, the chairman of the committee.

WE hear that Sir William Thomas Lewis has made donation of £1,000 to the Cardiff Infirmary.

MR. GEORGE HERRING, whose munificent donations to the Hospital Sunday Fund amount to over £50,000, has consented to identify himself more with the work, and was appointed to the Committee last week.

THE sum of £1,000 has been presented by Mr. Edward Heron-Allen to the Westminster Hospital to endow a bed in one of Dr. Murrell's wards in recognition of his valuable contribution to pharmacology and "Researches on the Action of Remedial Agents in the Treatment of Disease."

Special Correspondence.

[FROM OUR OWN CORRESPONDENT.]
SCOTLAND.

UNIVERSITY OF EDINBURGH.—During the past year the total number of matriculated students, including 317 women, was 3,000, the highest number reached for eleven years. The students enrolled in the Faculty of Medicine numbered 1,480, of whom 583 belonged to Scotland, 352 to England and Wales, 113 to Ireland, 74 to India, 238 to the Colonies, and 20 to foreign countries. The degrees of M.B., Ch.B., were conferred on 161 candidates, including 12 women; of M.B.C.M., on 4; and of M.D. on 61. Fifty-four graduates, including 6 women, received the special University certificate in diseases of Tropical climates. In response to the appeal made to the public for funds to aid in the development of the university, Sir Donald Currie has made the munificent gift of £25,000, which is to be known in the future as the Sir Donald Currie Lectureship Endowment Fund. Other contributions to the extension fund amounting to £15,000 have been intimated, including £5,000 from Sir John Jackson, to the Tait Memorial Fund for the encouragement of physical research. The University have purchased the Old City Hospital and Grounds from the Town Council, and the buildings thus acquired are to be adapted to the purposes of the natural philosophy and engineering departments. Although the Carnegie Foundation has not had an appreciable effect in increasing the number of students, it is noticeable that many take out more classes than they would probably otherwise have done. A lectureship in military subjects has recently been instituted in co-operation with the War Office; the course of instruction extends over three winter sessions. Dr. J. O. Affleck and Dr. C. B. Ker have been appointed University Lecturers in infective diseases, and a lectureship in the Practical application of anaesthetics has been instituted, to which Mr. T. D. Luke, F.R.C.S.E. has been elected. The additions to the library numbered 1973, being an increase of 700 over the previous year; the re-cataloguing of the library is now practically completed, 210,000 volumes in the general library, and several departmental libraries having been dealt with in the process. The question of printing the catalogue will have to be considered as soon as the alphabetical arrangement is complete, but meanwhile the printing of a short catalogue of some 25,000 volumes for the use of readers is proceeding, and will, it is hoped, be finished during the year. In the library itself a great improvement, both as regards space, and security from fire, has been the introduction of a system of steel shelving of the most approved type.

[We do not hold ourselves responsible for the opinions of our correspondents.]

PROPOSED STERILISATION OF CERTAIN DEGENERATES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.
SIR,—Every earnest worker at social problems deserves respect. Dr. Rentoul's earnestness is unmistakable, otherwise one might find it difficult to

refrain from ironical treatment of his writings on the above-named subject. What does Dr. Rentoul think would be the fate of anyone, who in the present state of the law should proceed to sterilise a degenerate without the consent of the patient? What the penalty might be under the criminal law may be uncertain; but there can be little doubt about the amount of damages an injured individual would be awarded by a British jury in an action in the civil courts. Sterilisation of degenerates would need the sanction of the law before it could be practised. Does Dr. Rentoul think such a project of law is anywhere within reasonable distance of the sphere of practical politics? Can he conceive of a Government introducing such a measure? Can he imagine the shouts of laughter that would greet the presentation of such a Bill by a private member? Every sensible member of Parliament, as well as every student of sociology, would at once suggest the necessity first of all of attacking the known causes of degeneracy. Syphilis, tuberculosis, rickets, drink, poverty, vice, crime—these are some of the chief causes of degeneracy, all mitigable or removable. Enforcement of the Public Health Acts thoroughly would in itself form a long step in this direction. In many or most districts these laws are largely neglected owing to the ignorance or selfishness of the men composing local authorities. The medical officer of health in many places is the ill-paid servant of vulgar men, and, being unsupported by public opinion, is unable to urge upon the authority, much less to ensure, enforcement of the law in his district. In most small urban, and in most rural districts, men of education and position decline to take office on the council, whilst the Local Government Board never interferes unless an epidemic or a similar emergency arises. Even in many villages within fifty miles of London, many of the poor are housed in a fashion as to sanitation and water supply which few of their wealthy neighbours would allow for many days in the case of their favourite horses. If Dr. Rentoul will direct his energy to rousing the conscience of the whole people by bringing before them the national perils which undoubtedly surround them through neglect of their duty as citizens, he will do some good. If the same amount of human energy, and of money—many millions annually—now devoted to attempts to convert the foreign heathen were directed wisely to solution of the social problem at home—to conversion of our own pagans and savages to a higher plane of civilisation—the need for sterilisation of degenerates, among other mitigating remedies for the symptoms of the foul social diseases of the age, would be soon put an end to.

I am, Sir, yours truly,
A STUDENT OF SOCIOLOGY.

Jan. 12th, 1905.

HOSPITAL FUNDS AND SMALL HOSPITALS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.
SIR,—Mr. Sewill, having appointed himself arbitrator, gives his considered judgment that the general hospitals are almost perfect, ignoring the waste of the £39,000 a year H.R.H. the Prince of Wales drew attention to. As I do not agree with him either in his self appointment as judge or with his finding, he accuses me of "confusion of thought with regard to the main issues."

These issues were twofold—(1) the necessity for the abolition of the special hospitals, and (2) the wickedness of advertising, when attempted by one outside the sacred ring. The latter I congratulate Mr. Sewill on having at last ceased to mention. As regards the first, I would ask Mr. Sewill to take perhaps the most evident case, what was the position of ovariectomy in the general hospitals before Spencer Wells established the operation in London? I am old enough to remember when there were no special throat, ear, eye, or skin departments in many general hospitals, and I fail to see why, because the general hospitals have been compelled to follow and make special departments, that this is a good reason for the abolition of the small hospitals.

Instead of a column of platitudes will Mr. Sewill, in support of his claim to almost perfection, answer my question about ovariectomy, and will he also tell us how he explains away the waste of £39,000 a year.

I am, Sir, yours truly,

OUTSIDER.

Obituary.

SIR JAMES LOUIS DONNET, K.C.B., R.N.,
M.D.St. AND., L.R.C.S.Ed.

THE death is recorded of Sir James John Louis Donnet, K.C.B., Inspector-General of Fleets and Hospitals, R.N., retired, on the 11th inst., at the residence of his daughter, at Bognor, in his eighty-ninth year. Sir James Donnet was the son of Surgeon Henry Donnet, R.N., by his marriage with Elizabeth, daughter of Mr. John Moore, of Dublin, Philadelphia, and Gibraltar. He was educated in Paris, Edinburgh, and London, and joined the Navy as an assistant surgeon in 1840. In this rank he was present in the "Vesuvius" at the operations on the coast of Syria and at the siege and fall of St. Jean D'Acre, and he had charge of the R.M. Hospital at Acre after the fall of that place. One notable service was with the Arctic expedition of 1850-51, in the "Assistance," when the first footprints of Franklin were discovered, and then, three years later, as senior medical officer of the flagship "President," at the attack, during the Russian War, of the allied squadrons on the stronghold of Petropaulowski, in Kamschatka. He was promoted to the rank of deputy Inspector-General in 1867, and to that of Inspector-General in 1875, and in those ranks, before his retirement in 1876, he filled many important posts in or connected with the medical service of the Navy. His many services were recognised in 1870 by his appointment as honorary surgeon to Queen Victoria, in 1878 he was awarded a good service pension, in 1893 he became an honorary physician to Queen Victoria, and in 1897 he received the honour of a Knight Commandership of the Bath. At the time of his death Sir James Donnet was an honorary physician to the King. Sir James married in 1852 Eliza (who died in 1903), daughter of Mr. James Meyer.

OGILVIE GRANT, M.B.Ed., D.P.H., L.R.C.P.Ed.,
OF INVERNESS.

WE regret to announce at the early age of forty-eight years, the death of Dr. Ogilvie Grant, medical officer for the county and burgh of Inverness, at the residence of his brother, Maryhill, Inverness, on the 9th inst. Dr. Ogilvie Grant was educated at Inverness Royal Academy, Edinburgh Academy, and in the University of that city, he distinguished himself in English literature, classics, and mathematics, afterwards bringing his medical studentship to a close with the degree of M.B., C.M., in 1881. After some useful Continental experience, Dr. Grant started a private practice in Inverness, and soon took a prominent part in the professional and intellectual life of the town.

GEORGE FREDERICK CHADWICK, L.R.C.S.,
L.R.C.P., L.F.P.S.Glas., OF STOCKPORT.

WE regret to announce the sudden death of Mr. George Frederick Chadwick, a well-known Stockport medical practitioner, on the 7th instant. He complained of indigestion, and died before a doctor could be sent for. Deceased was educated at Owens College, Manchester, and in 1891, took the diploma of L.R.C.S., L.R.C.P.Ed., and the L.F.P.S.Glasgow.

EUBULUS WILLIAMS, M.D.St. AND., M.R.C.S.ENG.
L.S.A., OF BRISTOL.

WE regret to announce the death of Dr. Eubulus Williams, the well-known homœopathic practitioner, at his residence, Clifton, on the 9th inst., in his seventy-fourth year. Dr. Williams was born at Williton, Somerset, fifth son of the late Mr. Joseph Williams. He was educated at Taunton College, and matriculated

at London University, afterwards becoming a student at Guy's Hospital. Soon after taking his surgeon's degree, in 1853, Dr. Eubulus Williams was appointed house surgeon to the Reading Hospital, and in 1855 was elected medical superintendent to the Dundee Royal Infirmary. In 1858 he began practice in Bristol, and joined in working a dispensary in St. James's Square, Bristol, for diseases of women and children, and when the dispensary was merged in the Children's Hospital. Dr. Williams was elected on the surgical staff. On embracing homœopathic principles, he gave up his connection with the Children's Hospital, but was re-elected senior surgeon in 1863.

BRIGADE-SURGEON JAMES DOW SAINTER, who joined the Army in 1859, and served throughout the China Campaign of 1860, died recently at Craigellachie at the age of seventy, having retired from the Army in 1880.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A QUARTERLY MEETING of the Council was held at the Royal College of Surgeons on Thursday, the 12th inst., Mr. John Tweedy, President, in the chair. Mr. Bernard Pitts, F.R.C.S., made the required declaration and was re-admitted a Member of the Court of Examiners. The death of Mr. A. Quarry Silcock, a Member of the Court of Examiners, was reported, and a vote of condolence was passed with his widow and family. The President stated that the vacancy in the Court of Examiners thus occasioned would be filled up at the next meeting of the Council in February, together with the vacancy occasioned by the expiration of the period of office of Mr. W. H. A. Jacobson.

Diplomas of Fellowship were issued to John Hay Burgess, M.B.Lond., and Noel Everard Waterfield, M.B.Lond.

Diplomas of Membership were issued to the following candidates:—Wilfred Edward Brierley (Worcester), Joseph William Evans (Charing Cross Hospital), Edward Ernest Mossop (Cape Town), and Alfred Spitteler (Bombay).

Diplomas for the Licence in Dental Surgery were issued to the following candidates:—Alexander Henry Craig (Belfast), Herbert John Tindall (Ipswich), and Henry Harrison Tomlinson (Cheshire).

A report was received from the President and Vice-Presidents regarding an offer made by Mrs. Macloghlin, of Southport, to found Scholarships in memory of her late husband, Mr. E. Percy P. Macloghlin, M.R.C.S., formerly in practice at Wigan.

Mrs. Macloghlin's offer is made in accordance with the intention and expressed desire of her husband, and she proposes in five years from his death, to give to the College a sum of £10,000 for the purpose of endowing these Scholarships, which are intended to assist young students in need of financial help to proceed with their professional studies.

The Council gratefully accepted Mrs. Macloghlin's munificent offer, and agreed to administer the Trust which had been arranged by the President and Vice-Presidents in consultation with Mrs. Macloghlin.

Dr. H. Timbrell Bulstrode was appointed to represent the College at the Conference on School Hygiene arranged by the Royal Sanitary Institute to be held in London next month.

Mr. Edmund Owen presented to the College, on behalf of Mr. Edward Atkinson, M.R.C.S., of Leeds, six saws invented and used by William Hey for operations on the skull, and a vote of thanks was accorded to Mr. Edward Atkinson for his very interesting gift.

La Revue Internationale de la Tuberculose, edited by Dr. S. Bernheim, Paris, and published for the last three years in French, Italian, and Spanish, will, from January, 1905, be edited in English as well in order to satisfy the request of a great number of English and American medical men.

ARRANGEMENTS have been made by the Hamburg-American Steamship Co., to organise sea voyages for the benefit of the tuberculous. The first boat sails at the end of the month.

Medical News.

Medical Sickness and Accident Society.

THE usual monthly meeting of the Executive Committee of the Medical Sickness, Annuity and Life Assurance Society was held at 429, Strand, London, W.C., on the 30th ult. There were present Dr. de Havilland Hall, in the chair; Dr. J. Pickett, Dr. W. Knowlesley Sibley, Mr. H. P. Symonds, Dr. Fredk. S. Palmer, Dr. J. W. Hunt, Dr. M. Greenwood, Dr. St. Clair B. Shadwell, and Dr. J. B. Ball. The accounts presented showed that the sickness claim account has been much increased by members suffering from influenza. The claims have been of short duration, although numerous, and the total amount in 1904 will be found satisfactory. The bonuses at age of sixty-five, resolved on at the last general meeting, have been paid, about one thousand pounds having been disbursed in this manner. This bonus has been an agreeable surprise to most of the recipients, whose letters show how greatly they have appreciated it. Prospectuses and all particulars on application to Mr. F. Addiscott, Sec., Medical Sickness and Accident Society, 33, Chancery Lane, London, W.C.

The Pharmaceutical Society of Great Britain.

THE council of the Pharmaceutical Society of Great Britain has resolved that the Pharmacy Acts Amendment Bill shall be introduced into the House of Commons at the earliest opportunity. The council proposes a clause to prohibit absolutely the use of the title of "chemist" or "druggist," or "chemist and druggist" by limited companies, and to prevent such companies carrying on the business of a chemist and druggist unless one of the directors of the company, and all assistants in charge of branch shops, are duly registered chemists. Further, anything which would be an offence under the Pharmacy Acts if committed by an individual, will, according to this clause, be an offence for which all the directors of a limited company will be liable if done on behalf of the company. The Bill will probably be introduced by Mr. T. Lough, M.P., and a large number of members on both sides of the House have already promised their support.

Hygiene and Physical Degeneration.

AN interesting meeting was held in Dublin on the 9th inst., under the auspices of the Irish Association for the Prevention of Intemperance, when Professor Sims Woodhead delivered a lecture on the question, "How Far is Physical Degeneration the Result of Bad Hygiene and Intemperance?" Without committing himself as to whether there is any deterioration of the physique of the people really going on, the lecturer made the safe assertion that there is ample room for improvement. The secret of physical and intellectual fitness was nutrition, and the conditions of good nutrition were the conditions of good hygiene. Of these the most important were good air and wholesome food. Alcohol, by its interference with the growth and nourishment of the cells of the body, exerted a damaging influence on vitality. In particular, alcoholism predisposed towards phthisis, and was an important causal factor in regard to insanity. He noticed with satisfaction the diminution in the use of alcohol in the treatment of the sick, being himself somewhat sceptical of its usefulness under any conditions. Dr. James Little, who presided, contrasted the physique of British workmen with that of the workmen of Berlin and the North of Germany, to the advantage of the latter. He believed that our people are steadily degenerating. Sir Lambert Ormsby, who also spoke, drew attention to the need of the working classes of our great cities for better housing, and urged the establishment of gymnasia and places of healthy amusement as counter-attractions to the public-house.

Society for Relief of Widows and Orphans of Medical Men.

A QUARTERLY Court of the Directors of the above Society was held at 11, Chandos Street, W., on January 11th, Mr. Christopher Heath, President, in

the Chair. The President announced the death, on January 5th, of Mr. J. B. Blackett, who had filled the office of Secretary to the Society for thirty-seven years, and the following resolution was unanimously passed: "That this Court has received with deep regret the announcement of the death of Mr. Joseph Blackett, M.R.C.S., who has so ably filled the office of Secretary to the Society for the Relief of Widows and Orphans of Medical Men since 1868. The Court desires to place on record its appreciation of the valuable services of Mr. Blackett to the Society, and of his unvarying kindness to and consideration for the annuitants of the Charity; and wishes to convey to his family its sincere sympathy in their bereavement." Fifty-two widows and 16 orphans had received a Christmas present, amounting in all to £574, in addition to their annuities. A sum of £1,293 was allotted in payment of the half-yearly grants to the annuitants. Four new members were elected, and one new application on behalf of a widow was received. Four applications for the vacant office of secretary were received and considered, and Mr. Edward J. Blackett, M.R.C.S., L.R.C.P., was elected to succeed his father as secretary.

The British Gynaecological Society.

AT the annual meeting of this Society, held on Thursday, January 12th, 1905, the election of the officers and council for the current year resulted as follows:—

Hon. President.—R. Barnes, M.D., F.R.C.P., F.R.C.S.

President.—William Alexander, M.D., M.Ch., F.R.C.S. (Liverpool).

Vice-Presidents.—E. Stanmore Bishop, F.R.C.S. (Manchester), Bedford Fenwick, M.D., M.R.C.P. (London), F. Bowreman Jessett, F.R.C.S. (London), R. P. Ranken Lyle, B.A., M.D., B.Ch. (Newcastle-on-Tyne), Sir A. V. Macan, M.A., M.B., M.Ch., M.A.O., F.R.C.P. (Dublin), J. Jameson Macan, M.A., M.D. (London), H. Macnaughton-Jones, M.D., F.R.C.S.I. (London), Christopher Martin, M.B., C.M., F.R.C.S. (Birmingham), J. A. Mansell-Moullin, M.A., M.B., M.R.C.P. (London), Thomas Oliver, M.A., LL.D., M.D., F.R.C.P. (Newcastle-on-Tyne), Heywood Smith, M.A., M.D., M.R.C.P. (London), and W. Dunnett Spanton, F.R.C.S. (Hanley).

Hon. Treasurer.—W. H. Simon, M.D., F.F.P.S. (London).

Council.—T. Gelston Atkins, B.A., M.D., M.Ch. (Cork), N. T. Brewis, M.B., C.M., F.R.C.P., F.R.C.S. (Edinburgh), G. Roe Carter, M.R.C.P.I. (London), Sir J. Halliday Croom, M.D., F.R.S.E. (Edinburgh), William Duncan, M.D., M.R.C.P., F.R.C.S. (London), F. Edge, M.D., M.R.C.P., F.R.C.S. (Wolverhampton), George Elder, M.D., C.M. (Nottingham), T. J. English, M.D. (London), J. H. Ferguson, M.D., F.R.C.P., F.R.C.S. (Edinburgh), Clement Godson, M.D., M.R.C.P. (London), Arthur Helme, M.D., M.R.C.P. (Manchester), R. J. Kinkead, A.B., M.D. (Galway), J. Macpherson Lawrie, M.D. (Weymouth), Samuel Lloyd, M.D. (London), John Padman, M.R.C.S. (London), Ernesto Pestalozza, M.D. (Florence), J. J. Redfern, M.A., M.D., M.Ch., M.A.O. (Croydon), Charles Ryall, F.R.C.S. (London), R. T. Smith, M.D., M.R.C.P. (London), J. H. Swanton, M.A., M.D., M.Ch., M.R.C.P. (London), J. W. Taylor, M.Sc., M.D., F.R.C.S., (Birmingham), W. Travers, M.D., F.R.C.S. (London), H. F. Vaughan-Jackson, M.R.C.S., L.R.C.P. (Potter's Bar), and Hugh Woods, B.A., M.D., B.Ch., M.A.O. (London).

Editor of the Journal.—J. J. Macan, M.A., M.D. (London).

Assistant Editor.—J. Hutchinson Swanton, M.D.

Hon. Secretaries.—Sol Jervois Aarons, M.D., C.M., M.R.C.P., and Smallwood Savage, M.A., M.B., B.Ch., F.R.C.S.

Auditors.—C. H. Bennett, M.D., and F. A. Purcell, M.D.

Trustees of the Property of the Society.—G. Granville Bantock, M.D., F.R.C.S., R. S. Fancourt Barnes, M.D., F.R.S.E., and Clement Godson, M.D., M.R.C.P.

Notices to Correspondents, Short Letters, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a distinctive signature or initials, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

ORIGINAL ARTICLES or **LETTERS** intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in re-forwarding from office to office. When sending subscription^s the same rule applies as to office, these should be addressed to the Publisher.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

ET OFFERA.—We think that before legal proceedings are taken another attempt should be made, preferably by a mutual friend, to adjust the matter in dispute.

M. D., F.R.C.S.—The dislocation of their medical practice caused by the attendance of medical men at the Law Courts is well known to the judges and barristers; and the latter, in agreement with the solicitors of the case, generally do their best to minimise the inconvenience which may arise. Our correspondent, therefore, should place his position before the latter, and request the favour of being only summoned to attend at the last moment necessary for his evidence.

PUBLIC HEALTH.—We have never heard of any such patent. But inquiry might be made at the Patent Office.

GENERAL PRACTITIONER.—Adenoids are very rare in late life. A case, however, has been recorded in an old man of 70 years.

LUMBRICATE.—Our correspondent had better seek the advice of an ophthalmic surgeon.

M.D. Lond.—Yes, as soon as the report reaches us.

BROMATIS (Bolton).—In answer to your query we would advise you to look up the admirable "Practice of Medicine" recently edited by Dr. Bain. You will find there a short but clear account of the many bacteria commonly met with in the human mouth. Of these several are pathogenic, such as staphylococcus pyogenes aureus and albus; streptococcus pyogenes, diplococcus pneumoniae and micrococcus tetragenus. In addition, there are of course a number of adventitious pathogenic organisms.

EMERITUS.—We are surprised to hear that in the local institution you mention the possession of an English qualification is obligatory on all members of the medical and surgical staff. The exclusion thereby of Scotch and Irish qualifications inflicts a great and undeserved injustice upon a large number of medical men. We feel sure that if this matter were brought dispassionately and clearly before the governors of the charity they would not tolerate so great an anomaly, especially as it excludes from important posts those who are in many cases their own medical attendants. It would be well to call together the Scotch and Irish diplomates of your neighbourhood to consider the question. In your own case we should advise you to join the newly formed Association of Scotch Diplomates.

F. K. BROWN.—(1) Write to the Secretary of the College, who will give you the requisite information. (2) Apply to the Local Government Board.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, JANUARY 18th.

SOCIETY OF ARTS (John Street, Adelphi, W.C.).—8 p.m. Paper:—Capt. L. James: Wireless Telegraphy and War Correspondence.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY (20 Hanover Square, W.).—5.30 p.m. Paper:—Dr. C. W. Buckley (Buxton): Climatology from a Medical Standpoint.

ROYAL METEOROLOGICAL SOCIETY (Institution of Civil Engineers, Great George Street, Westminster, S.W.).—7.30 p.m. Ordinary Meeting. 7.40 p.m. Annual General Meeting. Election of Officers and Council for the ensuing year. Address:—The President (Capt. D. Wilson-Barker): The Connection of Meteorology with other Sciences.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chancery Street, W.C.).—4 p.m. Mr. G. L. Obesale: Clinique. (Surgical.) 5.15 p.m. Dr. D. Grant: The Treatment especially Intra-Nasal, of Suppuration in the Nasal Sinuses.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith Road, W.).—5 p.m. Dr. Beppard: Practical Medicine.

CENTRAL LONDON THROAT AND EAR HOSPITAL (Grey's Inn Road, W.C.).—5 p.m. Demonstration:—Mr. Nourse: Nasal and Aural Accessory Sinuses.

THURSDAY, JANUARY 19th.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22 Chancery Street, W.C.).—4 p.m. Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m. Mr. J. Clarke: Recent Improvement of Painful and Deformed Feet.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—4.30 p.m. Dr. A. E. Giles: Uterine Displacements.

MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (7 Fitzroy Square, W.).—8 p.m. Lecture: Sir William Broadbent: The Examination of the Heart and what may be learned from it. (Post-Graduate Course)

FRIDAY, JANUARY 20th.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN (11 Chandos Street, W.).—5.30 p.m. Cases and Specimens will be shown by Dr. W. H. Kelson, Dr. A. Morrison, Dr. L. Guthrie, Mr. G. Pernet, Mr. F. Jaffray, Mr. D. Armour, Dr. E. Pritchard, Dr. J. G. Emanuel, and Dr. G. Carpenter. Paper:—Mr. D. Drew: On a Case of Vesical Urteral, and Renal Calculus in a Child.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chancery Street, W.C.). 4 p.m. Dr. St. Clair Thomson: Clinique. (Throat.)

MONDAY, JANUARY 23rd.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN, (20 Hanover Square, W.).—On Monday Jan. 23rd, A Casual Communication by Mr. J. B. Parfitt, L.R.C.P., M.R.C.S., L.D.S. Eng., on "An Extreme Case of Saddle-shaped Arch." Paper by Mr. E. Denison Pedley, F.R.C.S.E.D., M.R.C.S., L.D.S. Eng., on "The Relationship between Dental and other Diseases."

Vacancies.

Ashton-under-Lyne, District Infirmary and Children's Hospital.—Resident House Surgeon. Salary £180 per annum, with board, washing and lodging, gas, fire, and attendance. Applications to the Honorary Secretary, Leonard Bottomley, 120 Stamford Street, Ashton-under-Lyne.

East Sussex County Asylum, Hellingly.—Senior Assistant Medical Officer. Salary £200 per annum, with board, lodging, washing and attendance. Applications to Reginald Blaker, Clerk to the Visiting Committee, 211, High Street, Lewes.

Chester General Infirmary.—House Surgeon. Salary £100 per annum, with residence and maintenance in the house. Applications to the Chairman of the Board of Management.

County Asylum, Rainhill, near Liverpool.—Assistant Medical Officer. Salary £150 per annum, with furnished apartments, board, attendance, and washing. Applications to the Medical Superintendent.

Monmouthshire Asylum, Abergavenny.—Junior Assistant Medical Officer. Salary £150 per annum, with board, lodging and washing. Applications to the Medical Superintendent.

Newcastle-on-Tyne Dispensary.—Visiting Medical Assistant. Salary £160 per annum. Applications to the Honorary Secretary, Joseph Carr, 41 Kosley Street, Newcastle-on-Tyne.

National Hospital for the Paralysed and Epileptic, Queen's Square.—Nervous Diseases Research Fund.—Director of Neuro-pathological Research. Salary £250 per annum. Applications to Edgar Speyer, Esq., Chairman of the Fund, National Hospital for the Paralysed and Epileptic, Queen's Square, W.C.

Manchester Hospital for Consumption and Diseases of the Throat and Chest.—Resident Medical Officer. Salary £100 per annum, with board, apartments, and washing. Applications to C. W. Hunt, Secretary.

Dudley Dispensary.—Resident Medical Officer. Salary £150 per annum. Applications to Henry C. Brettell, Hon. Sec. Jaffray Branch of the General Hospital, Gravelly Hill, near Birmingham.—Resident Medical and Surgical Officer. Salary £170 per annum, with board, residence and washing. Applications to the House Governor, General Hospital, Birmingham.

Parish of St. Giles, Camberwell.—Assistant Medical Officer at the Infirmary, Brunswick Square, Camberwell. Salary £120 per annum, with apartments, board, and washing. Application to the Medical Superintendent at the infirmary.

Appointments.

BREWSTER, J. M., L.R.C.P.I., L.S.A., Certifying Surgeon under the Factory, Act for the Biddington District of the County of Nottingham.

CLAPP, GEORGE TUCKER, M.B. Cantab., M.R.C.S., Medical Officer to the Exeter Post Office Staff.

CORNER, EDWARD M., M.B. Camb., F.R.C.S., Consulting Surgeon to the Bowes Park Cottage Hospital.

COWIE, J. A., B.A., B.Sc. N.Z., M.B., Ch.B. Glasg., M.R.C.S. Eng., L.R.C.P. Lond., Assistant House Surgeon to the Royal Devon and Exeter Hospital.

LEES, HAROLD C., M.B. C.S., L.R.C.P. Lond., M.B., B.S. Lond. Junior House Surgeon at the Blackbura and East Lancashire Infirmary.

MACKEZIE, H. VALENTINE, M.D., C.M. Edin., Honorary Ophthalmic Surgeon to the Moretonhampstead (Devon) Cottage Hospital.

Births.

PRIDIE.—On Jan. 12th at Wansford, Northamptonshire, the wife of Hugh Hampden Pridie, M.B., of twin daughters.

Marriages.

WHOLEY—HUNTER.—On Jan. 7th, at St. Martin's-in-the-Fields, Thomas Wholey, M.B., Dunelm, to Agnes Eveline, daughter of the late Lowther Hunter, Esq., and of Mrs. Hunter, of Rockville, Burlington Place, Eastbourne.

Deaths.

MANBEY.—On Jan. 11th, at Brookfield, London Road, Southend-on-Sea, Georgianna Manbey, widow of late George Manbey, Esq., M.R.C.S.

The Medical Press and Circular.

Original Communications.

TWENTY YEARS OF OPERATIVE GYNÆCOLOGY. (a)

By PROFESSOR JOHN W. TAYLOR, M.D.,
F.R.C.S., &c., &c.,
Birmingham.

AFTER reviewing the progress of gynæcology during his year of office, the work of the Society, and the losses sustained by the profession from the deaths of eminent men, Professor Taylor said:—

Twenty years ago I joined you as a Foundation Fellow, and for twenty years I have been engaged in the practice of operative gynæcology. The table which I show gives a yearly record of all the abdominal sections I have performed on women during this period. The cases are strictly consecutive and the total number of sections is 1,291. The total mortality is 85, or 6·5 per cent.

On examining this mortality more closely I notice that a large proportion of the deaths were unavoidable, or were only indirectly due to the operation. One patient was attacked by apoplexy during anæsthesia, and eventually died from this, the operation (a resection of bowel) being perfectly satisfactory, as proved by *post-mortem* examination. Five of the patients suffering from acute perforative peritonitis; (b) four with intestinal obstruction were almost moribund at the time of operation, and many others (no less than 22) suffering from malignant disease, died rather from the original affection than from the operation, exploratory or otherwise, which was undertaken for their possible relief.

There are, however, certain other cases of failure which are and must remain a trouble to me, especially some early cases of sepsis after operation, some cases of secondary hæmorrhage, and, finally, some cases of difficult myoma operated upon during a time of transition, when the old operation of the clamp (perfected so far as it could be, I think, by a method of my own) was slowly giving way to the more modern and better methods of supra-vaginal amputation and pan-hysterectomy.

I did the (then) more difficult operation under very bad conditions, and my work suffered accordingly. If I and some of my patients had been able to wait for riper experience, I think the result in all of these cases might have been different. In one instance of a neglected myoma, I met with a greater amount of peritoneal displacement than I have ever seen or read of elsewhere, and it may perhaps be of service to record it here. The descending and transverse colon had been raised by the growth of an enormous tumour of the left side so that the transverse colon passed from right to left across the middle of the back of the tumour,

and the omentum formed a cap covering the summit of the growth and falling to some extent over its anterior surface. The almost irresistible inference at first was that the transverse colon was adherent to the back of the tumour. It was indeed closely attached everywhere to the tumour, but by peritoneal displacement, and not by adhesion.

In concluding here my references to the record of deaths, I think I am justified in noting that I have, I hope, learnt something from my failures, and that in spite of, or rather perhaps by virtue of, advancing years, and by virtue of some teachableness, my last five or six years of work have been my best years, and the last year is, on the whole, the best of all, giving, with a fair proportion of grave and important work, a death-rate of only about 1 per cent. This, I think, may deservedly give more weight to the remarks I wish to make on the progress of my practice. I can remember the faulty septic days, when from ignorance little or nothing was left undone that could encourage sepsis; the days of more or less empirical asepsis, when men were stumbling as if blindfold towards a path of safety; and the later years, when the darkness had lifted and one could see the plain outlines of the road which led towards the goal. All this time, during which I have myself been working, has been a time of searching for better methods of asepsis and a time of experiment in this direction.

The first dawning for me (I speak for myself) came with the definite recognition of the mathematical value of heat in sterilisation. The full grasp of this all-illuminating fact made the continued use of the old sponge impossible, and this was cast aside for the artificial sponge of gauze which, like the instruments, the towels and the dressing, could be subjected to a really sterilising bath or atmosphere.

Next to this, there is nothing which has given me so much satisfaction and confidence in all my later work as the adoption of the permanganate of potash and oxalic acid method of Kelly for the sterilisation of the hands of myself, assistant, and chief nurse or nurses. This method, first introduced at Sparkhill by my colleague, Mr. Martin, and supplemented in my own practice by the additional use both of methylated spirit and solution of the red iodide of mercury—a method employed, not only at the time of operating but immediately after touching any case or dressing that may leave serious contagion behind it—has proved a much more trustworthy proceeding than anything I had previously tried. It is not difficult to obtain, the drugs are common and inexpensive; it requires no measurement, the solutions are saturated; it is not hurtful to the hands, as are all the carbolic acid compounds and derivatives, and I do not think that since I have regularly employed it I have had any case of sepsis that can be reasonably referred to hand infection. I believe if this method were generally used by practitioners and nurses, not only before the operative work of a confinement, but immediately after any dangerous contact in ordinary practice, it would be possible to eliminate the danger that undoubtedly still remains in private midwifery practice.

(a) The President's Valedictory Address, delivered at the Annual Meeting of the British Gynæcological Society, January 12th, 1905.

(b) One of these was a case of Cæsarian section. The infant is still living.

Perhaps you will pardon a palpable digression if I briefly relate an instance which seems to throw some side-light on the value of the method.

The children of a practitioner who was well known to me had suffered for several years from tinea tonsurans. They had received the best dermatological advice and treatment, but the disease persisted and threatened to injure or stop their education. The skin was unbroken, and I suggested that the method I used for my hands should be applied to the children's heads. This was done thoroughly, and within a few months no trace could be found of the complaint.

This is, of course, only a single instance, but others, who have more opportunity than I have of testing its value may be inclined to employ it further.

Next to the use of prolonged boiling and steaming for the sterilisation of everything necessary to the operation that can be so treated, and to the employment of the fortified Kelly's method for the hands, I know of no change which has been of greater service in my work than the discarding of the comprehensive single short ligature—like the Staffordshire knot—for the control of the pedicle or broad ligament and the use, instead of this, of a series of finer interlocking chain-ligatures.

These, if of silk, can be readily made aseptic by boiling in biniodide solution, so that every vessel can be controlled by its own sterilised ligature with but little or no tissue intervening, and this without causing any tension or dragging. In this way I am convinced the operator can best ensure himself against any danger of subsequent hæmorrhage.

I generally use a sharp, widely-curved needle of sufficient size to carry the No. 3 or No. 4 ligature silk easily. I thread it with a long length of silk and pass the needle through the broad ligament close to the ovarian vessels. One strand of the double silk is then cut, forming the ovarian ligature. The remaining strand is pulled further through the eye of the needle and the needle passed back through the broad ligament near to, but not including, the uterine vessels. The needle is cut off, leaving two further ligature loops, one for the uterine vessels and one for the middle of the broad ligament. The ligatures are interlocked and the pedicle tied in a chain of three ligatures. More may, of course, be used if this is considered advisable.

Closely connected with the use of this method of ligature is the employment of finer silk. Obviously, if but little beyond the vessel is enclosed in the ligature, finer silk may be used with perfect safety, and I employ this extensively both for the ligation of vessels and for the suture of peritoneum and fascia in the closure of the abdominal wound.

In fact, for many years now, I have used nothing but silk and silkworm-gut, finding that the finer sizes of the silk can be adequately sterilised by half an hour's boiling in biniodide solution, and that in time they are as perfectly absorbed as catgut.

Bearing, I believe, on the same point of a septic ligature is the interesting question of what has become of the lost disease "pelvic hæmatocele," or, as some prefer to call it, "broad ligament hæmatoma." Years ago, it was one of the commonest complications of the convalescence after operation. In our own hospital I remember the time when four or five patients were lying side by side, and all suffering from this same affection. Now it has so universally disappeared that I can easily imagine a student and observer of the present day hesitating to accept the experience of the older ovariologists on this subject. What is the cause of its disappearance? Many appear to have thought that the hæmatocele was secondary to some puncture of a vessel in the broad ligament due to the use of a sharp-pointed needle (though the favourite time of its onset was not until nine or ten days after operation), and that the accident was to be prevented by using a blunt pedicle needle. In the practice of several, the change in the use of the needle has been coincident with the disappearance of the tumour, but I believe it has been simply a coincidence.

As I have already said, I have largely gone back to the use of a sharp-pointed needle, but without finding any

recurrence of the hæmatocele. In the older days, I think the silk used for tying the pedicle was often septic, and a slow process of ulceration occurred, opening the vessels about a week or so after the date of operation.

In turning now to the consideration of special operations, I notice, first, that the removal of the uterine appendages for myoma has slowly given way in my practice to the operation of hysterectomy, both abdominal and vaginal, but I have not entirely given up the older operation. As I have, however, quite recently published my opinions on the choice of operation in myoma (a) there is no necessity for me to refer to it again, and I pass on to notice the marked change which has taken place in my practice regarding the removal of the appendages for tubal disease, and especially for disease due to gonorrhœal salpingitis.

The cases of this, numbering 20 in 1893 and 17 in 1894, have come down to an average of 4 or 5 in the last five years, and that this is not due simply to the adoption of vaginal rather than abdominal methods of operating is seen at once on looking at the statistics of both operations. The change is, of course, due to the systematic carrying out of the mercury and iodine treatment in all cases of gonorrhœal salpingitis, as advised by myself in the paper I read before this Society in 1899.

Not only is the operation of removal needed much less often than formerly, if this be done, but when acute pyosalpinx makes an immediate operation imperative. A vaginal celiotomy, with thorough emptying of pus sacs and drainage, followed up afterwards by treatment with the biniodide of mercury, is, in many cases, a better method of treatment than that formerly adopted. I shall, however, have to refer to this again later. The after-history of these cases, so far as I have been able to follow it, compares very favourably with that of the older cases of extirpation.

It may be well to note here that the gist and point of my previous communication on this subject has been very insufficiently grasped by many who have spoken and written regarding it.

The value of the treatment has nothing whatever to do with syphilis or its possible complications. Experience appears to show that the biniodide of mercury has a direct curative power in gonorrhœa, being, probably, slowly destructive to the gonococcus in the tissues.

Perhaps another digression may tend to enforce this. A gentleman contracted a gonorrhœa after an impure connection, and thereafter was troubled with a slight gleet which he could not cure. He became engaged to be married, and for eighteen months resided abroad, where he somewhat naturally either forgot his slight ailment or at all events let it alone. He came back to England three or four months before his proposed marriage and sought the very best advice for the cure of his gleet. Instruments were passed, he was assured that he might marry with safety, but the discharge was slightly increased rather than diminished by treatment. He married and within six weeks his young wife was suffering from double pyosalpinx with dangerous symptoms of peritonitis and high pyrexia. Pus had already formed, and the disease was much too acute for medicinal treatment alone to stay its progress.

I opened the pouch of Douglas, separated the adhesions, evacuated pus on both sides of the uterus and carried out prolonged pelvic drainage with iodoform gauze, keeping the patient all the time under treatment. She made a slow but very perfect recovery, and during this time I saw a good deal of her husband. He was still suffering—almost imperceptibly—but still suffering slightly from his chronic gleet, and I thought I had sufficient grounds for suggesting that he might very reasonably adopt the same medical treatment as that given to his wife. Both patients recovered completely. This is nearly five years ago. Shortly after his wife's recovery they went abroad to live and have, I understand, enjoyed the best of health ever since. Only a

(a) "Journal of Obstetrics and Gynecology," August, 1904.

few weeks ago a doctor who was associated with me in the treatment of the case stopped me very kindly to tell me of the very good health that both had enjoyed since they were under our care.

Turning now to the question of inguinal colotomy, there is a small detail in its performance which has proved of very great comfort to myself, and as I have never seen it mentioned by others I think it may be of service to describe it. I generally use the method introduced, I believe, by the French surgeon, Reclus, in which a spigot of glass is passed through the mesentery under the bowel, and the loop of colon rides over this, protruding from the incision. I guard against any danger of further protrusion of bowel by sewing the peritoneum to the loop of bowel all the way round by a continuous suture of fine silk. This, however, is not the innovation to which I want to draw your attention.

The bowel, as I daresay you know, is usually divided by the cautery straight down to the spigot on the third or fourth morning. Now this, though practically painless, I found out to be a very awkward proceeding, on account of hæmorrhage. As many as five or six large arterial vessels spouted at the deepest part of the division. The loss of blood was considerable. The clumsiness of the proceeding was manifested to the patient who was quite conscious, and there was decided pain and discomfort in seizing the bleeding points and applying ligatures. This may be entirely avoided, I find, by passing a ligature on each side of the spigot at the original operation and tying off a small amount of mesentery. The tying of the mesentery cuts off the full blood supply from the line of opening, and makes the subsequent division of the bowel (right down to the spigot) practically bloodless.

Speaking generally and very broadly, conservative operations on the uterine appendages by abdominal section have rather disappointed me, the benefit derived being rarely worth the waste of the abdominal incision. In order to understand me rightly, however it may be necessary to define more exactly what I mean by conservative operations on the appendages. I include in this the undoing of adhesions involving the appendages, but not those specially involving intestine. Some of the most perfect successes I have had after operation have been due to the undoing of intestinal adhesions, which caused incomplete obstruction and were a daily source of pain and misery, but were accompanied by no tangible lesion on examination. These obviously are essentially intestinal operations whatever may have been the cause of the original inflammation.

Again, though a few cases of hysteropexy and ventrosuspension have been included for the sake of convenience in my tabular statement (and rightly included) as "conservative operations," they are not really conservative operations on the uterine appendages.

By this term I chiefly mean salpingostomies, partial excision of the ovaries, ignipuncture of the ovaries, and shortening of the ovarian ligaments, with or without separation of adhesions from above; and it is these operations which appear to me to have been rather disappointing.

Some patients have been relieved, but few or none have reported themselves as quite well afterwards. In some cases the operation has appeared to do harm, and I have had to remove the appendages afterwards. In one case (and one only) has the operation been followed by a pregnancy. None of these operations have been undertaken rashly. On the contrary, I do not know any class of case in which I have expended more thought, caution and ingenuity—if I may term it so—in treatment.

In some of these cases—and this is a point which needs consideration before operation is proposed—I think there has been throughout some fatal want of correspondence between the sexual organs or functions of husband and wife which vitiated every attempt to give the patient perfect comfort. The utero-vaginal prolapse, painful retroflexion and prolapse of ovaries met with in some of these cases seem to be due directly to this and to be consequently almost incurable.

It may be a hard thing to acknowledge and accept,

but some women are undoubtedly unfit for the married life which has fallen to their lot, and no mere operative change can make them otherwise. For simple prolapse of ovaries due to backward displacement, the operation which has given me the best final results is that of simple shortening of the round ligaments without needless opening of the peritoneum.

My vaginal operations call for some passing commentary. I was considerably attracted at first by anterior vaginal cœliotomy, but have now practically abandoned it, as I dislike all methods of uterine fixation. But posterior vaginal cœliotomy has, in many ways, become more and more attractive to me. I recognise that it has a very special field of its own, and this field of usefulness needs a better recognition by the general, as well as by the gynæcological, surgeon. There are, for example, certain conditions requiring operative treatment in which the vagina is so infinitely better as a route for approach and treatment that I have no hesitation in saying the neglect of this and the use of the abdominal route instead may amount to bad practice.

Acute pelvic peritonitis due to gonorrhœa, when the mischief is mainly behind the uterus, and abdominal distension, peritonitic vomiting and sleeplessness from pain form a triad demanding immediate interference, is, as I have already said, pre-eminently such a case—a case for vaginal, rather than abdominal, operation.

Again, in some cases of abscess due to appendicitis, the pus tends to collect in the pouch of Douglas, while adhesions root in the abscess from above. In such cases the proper method of exploration is by the pouch of Douglas, and a life may easily be unnecessarily sacrificed by choosing the more usual incision. Even in virgins and young children the possible advantage of this route should never be forgotten or overlooked. Again, a peri-rectal abscess in the pelvis—sometimes a long-neglected pyosalpinx—not infrequently opens at the upper limit of the abscess sac into the rectum and discharges into this by overflow rather than by emptying. The patient falls into a condition of hectic, and, as some instructive *post-mortem* preparations show, has often died of her disease. Such a pus sac may, of course, be occasionally removed successfully from above, but in the condition of which I am speaking, the better practice is immediately to freely open up the pus sac from the pouch of Douglas or directly from the vagina, and establish rational drainage from the most dependent portion of the abscess. This is generally sufficient to ensure a quick and permanent recovery.

Again, there are cases of thrombotic pyæmia after parturition in which suppuration occurs in the immediate neighbourhood of the thrombus. The disease may sometimes be stopped and the patient cured by evacuation of the pus and gauze drainage well carried out, either through the pouch of Douglas or between the layers of the broad ligament. Some cases of this kind (included in my list) I hope to report more fully at a later period. All of these cases can only be treated satisfactorily by vaginal surgery. With less certainty, but still with marked advantage in special instances, vaginal ovariectomy and vaginal enucleation demand increasing consideration. I find I have used these operations in 10 or (really) 11 cases, and, under certain conditions—as when a single cyst is blocking the pelvis during labour and preventing a delivery—I hold vaginal ovariectomy as more than a fair alternative, but distinctly superior to abdominal removal. The great point of the *technique* of posterior vaginal section, apart from the disinfection of the vagina, is the use of the iodoform-gauze drain behind the uterus instead of any suture of the incision. This applies to vaginal hysterectomy, unless the sutures and raw surfaces are turned well outside the peritoneum as in the German method. The gauze drain prevents any danger of intestinal adhesions at the site of operation and effectually guards the patient from an adherent retroflexion as a late result of the vaginal interference. I often leave the drain *in situ* for twelve or fourteen days before removal. The only time when I have chosen closure instead of drainage has been when doing a vaginal ovariectomy during labour.

In this retrospect of work, I have endeavoured to touch lightly, but firmly, on the main points which strike me as definitely calling for reference. With the exception of the two digressions, I have written as tersely as I could, and much in the same way as one talks to a friendly colleague in the operating-room, when the operation is over and the surgeon for a brief period opens his heart and strives to give, as best he can, a simple statement of his work and the reasons of his practice.

The comradeship of the Society may, I hope, be trusted to condone any want of circumstance or ceremony in this presentation of my address. We are all travellers in a common journey, travellers who, in the graphic words of Mr. Cunningham Graham (a)—“kicking at our horses sides, straining our eyes, keep pushing forward, stumbling and objugating on the trail.” But we are more than this—we are explorers in an unknown country, over and over again, where no man has trod before us, where no certain trail can be found for us to follow, and where the talk round the camp fire at night, when occasion calls for it, cannot well be less or more than plain, straight and truthful.

Before I vacate the Chair, gentlemen, I want to say for you all and for myself, some words of welcome to our new President, Dr. Alexander. He is well known all over the world, and nowhere perhaps could we have found one whose reputation, ability, and kindness of heart so naturally entitled him to the honour and confidence of his fellows. We welcome him most heartily as our President, we assure him of our loyalty and support, and wish him every happiness and success in this his year of office.

A CASE OF OXALIC ACID POISONING WITH DEATH FROM PNEUMONIA.

By WILLIAM MURRELL, M.D., F.R.C.P.,
Physician to the Westminster Hospital.

POISONING by oxalic acid is by no means uncommon, but the following case presents certain points of interest. Oxalic acid is used for cleaning straw hats and other similar purposes, it can be obtained without difficulty, and it is cheap. As a suicidal agent it is less popular than carbolic acid and preparations of opium, but it comes third on the list in the case of women, and fourth with men. This difference in order is due to the fact that whilst prussic acid, cyanide of potassium and oil of almonds, all of which kill rapidly, are often resorted to as lethal agents by men, they are less commonly employed by females.

A tailor, *æt.* 50, was brought to the hospital by the police on December 6th, 1904, at 4 p.m., having been found in the street collapsed and vomiting. He stated that half an hour previously he had swallowed in tea two pennyworth of oxalic acid—probably about two ounces—with suicidal intent. He had been partly paralysed on the right side for four months, had been long out of work, and had been tramping the streets in search of employment. He had been without food for twenty-four hours, but during the morning had had three pints of beer. He was seen in the casualty room by Mr. E. C. Johnson, the house physician, who gave him large doses of saccharated solution of lime as an antidote, and then washed out the stomach with a solution of carbonate of lime, until the fluid returned clear and free from odour. The diagnosis was established by the presence of oxalate of lime crystals in the vomited matter, and subsequently in the urine. On admission to the

wards he was in a condition of collapse, his temperature being below 95°. He was given at frequent intervals hypodermic injections of strychnine. He vomited a little blood, but there was no diarrhoea, and the mucous membrane of the mouth was not excoriated. On the following day the temperature gradually rose from 98.2° to 100.8°, and the pulse-respiration ratio, taken at intervals, was 120 to 24, 125 to 26, and 148 to 32. His lips were swollen, he complained of sore throat and difficulty of swallowing, and there was much tenderness in the epigastrium. He was too ill to be examined thoroughly, and hypodermic injections of morphine were given to allay the pain. On the 8th there was a similar variation in temperature, which rose from 98° in the morning to 100.8° at night, the pulse-respiration ratio being 156 to 30 and 146 to 32, and the pulse small and soft. There was very little cough and no expectoration. The urine was of sp. gr. 1010, was acid and free from albumin. It contained spermatozoa in large numbers. On the 9th the temperature at 4 a.m. was 97°, at 4 p.m. 99°, after which it gradually fell. The pulse-respiration ratio was 138 to 36 and 140 to 42. At the right base posteriorly there was some dulness and the breath sounds were bronchial. There was much tenderness over the abdomen, but there was no blood in the motions. The kneejerks were brisk, the right being exaggerated; there was no ankle-clonus. On the morning of the 10th, the temperature was 96.6°, the pulse was 124 and the respirations were 26. He vomited after taking a little barley and albumen water, and died at 12.10 on the morning of the 11th, having survived the dose 104 hours.

At the autopsy made by Dr. R. G. Hebb it was found that there was some congestion of the pharynx, and the mucosa of the œsophagus, especially in the lower part, was swollen and of a dark red hue, with well-marked superficial veins. All the coats were thickened. The mucosa of the stomach were thick, soft, velvety, and smooth. There were no signs of ulceration anywhere, and there was no gangrene. The intestinal tract was normal. The lungs showed pneumonic consolidation of the right lower lobe, and to a lesser extent of the upper lobe, with hyperæmia of the left lung. The kidneys were normal.

The case presents many points of interest. In the first place, what dose was taken? The patient stated that he purchased two pennyworth, and inquiry discloses the fact that oxalic acid is usually sold retail in penny packets containing an ounce, so that probably he took two ounces. As the minimum fatal dose is one drachm, this may be regarded as a large dose. Taking this into consideration, it is curious that there was so little damage to the œsophagus and stomach. This may be explained partly by the early vomiting, and partly by the fact that the dose was well diluted. It was taken, we were told, in tea obtained at a coffee-shop, and probably in a large cup, or possibly in a half-pint mug. The prompt administration of a strong solution of lime and the repeated washing out of the stomach must have removed much of the poison and have neutralised the caustic effect of the remainder. It will be remembered that the liquor calcis saccharatus contains 8 grains of lime in the fluid ounce, and the liquor calcis only half a grain in the ounce. The discovery of oxalate of lime crystals in the vomit is obviously a useful guide to diagnosis in

doubtful cases. In the first specimen they were very small, and required a one-twelfth for their detection, but in the second specimen, after more lime had been administered, they were much larger, and were readily recognised. The presence of oxalate of lime in the urine can hardly be regarded as diagnostic. It is difficult to say what, if any, importance should be attached to the cloud of spermatozoa in the urine. Is this peculiar to oxalic poisoning, or does it occur in every case in which a lethal dose has been taken? It will be remembered that in death by hanging there is often a discharge of seminal or prostatic fluid.

In some cases of oxalic acid poisoning symptoms referable to the nervous system predominate, but they were absent here. Moreover, the mental condition was clear from first to last, and there were no indications of delusions, or of any form of insanity. The duration of life was exceptional, although not unprecedented, for in one case it is said to have been prolonged for thirteen days. The immediate cause of death was pneumonia. Was this primary or was it secondary to the effects of the poison? The probabilities are that it was primary, an acute lobar pneumonia, possibly influenzal in origin. The patient was suffering from the intense depression which marks the onset of the disease, and this, combined with the long abstinence from food, probably induced him to take the poison. The elevation of temperature, which would normally have indicated the progress of the lung condition, was masked by the collapse induced by the drug.

An inquest was held. What should have been the verdict? Should it have been pneumonia or oxalic acid poisoning?

THE GULF STREAM MYTH AND SEASIDE RESORTS.

By JOHN KNOTT, M.A., M.D. Dub., M.R.C.P.

SOME time ago I read with interested attention the article headed "Some Questions in Seaside Climatology," by Dr. Alfred F. Street, of Westgate-on-Sea, in the issue of THE MEDICAL PRESS AND CIRCULAR for December 2nd, 1903, in which the writer graphically and forcibly indicated the conspicuous attractions which that seaside resort offers to those in search of a residence specially suited to the improvement and maintenance of health. Foremost among these appears to be, in the opinion of Dr. Street, "that it enjoys almost the full advantage of the Gulf Stream, . . . to which we in these islands are indebted for the advantage, that though London has the latitude of Labrador, it has a far higher mean winter temperature." I had almost learned to think—or hope—that by this time the spirit of the "Gulf Stream myth" had been successfully "laid"; at least, the data for the exorcism have been sufficiently long before the scientific world for their effective application. It is now several years since the accomplished meteorologist, Mr. Henry Maitland Watts, in a "popular" scientific article, pointed out to the reading world, "That the belief that the Gulf Stream is the sole cause of the mild oceanic climate of Western Europe is still held by millions to-day, that it is still taught in public schools in England and in the United States, and that, although it is absolutely without any foundation whatsoever, it should have come to have all the sacredness of a gospel truth, is a tribute to its

attractive statement by one man and the hypnotic influence of one book. . . . In consequence, the 'Gulf Stream myth,' fathered by Maury, persists, while the broader, grander and more reassuring facts as to climate and weather causation are viewed with suspicion, and make slight headway against the universal acceptance of a theory that gained its whole value from the way it was stated by a strong man in the transition period in the development of an inexact science. The essential facts are that the Gulf Stream as an ocean current ceases to exist, that is, to differ in set and temperature from the rest of the ocean east of the longitude of Cape Race, Newfoundland."

Accordingly, we must learn to descend to the plain fact that the Gulf Stream does not, and cannot, convey warm water to the shores of Western Europe, there to modify the climate and give the British Isles the breezes of the "unvexed Bermudas," and Sweden and Norway the warmth of the Carolinas. The meteorologist who is conversant with the fundamental data on which his scientific specialty is based well knows that climatic causation is not a function of ocean currents, but of aerial currents; and easily grasps the fact that the mild oceanic climate of Western Europe is due to the distribution of the permanent aerial circulation over the whole Atlantic basin, of the moderating, mitigating effects of the ocean as a whole. This permanent circulation takes the form of a great cyclone in high latitudes, and of an enormous anti-cyclonic eddy in mid-latitudes; and it is to the mid-Atlantic anti-cyclone that must now be transferred the high climatic credit that has been unduly held by the Gulf Stream for so many years. Indeed, it is well known to the initiated that, allowing this vast aerial eddy to remain as it now is, and the general atmospheric drift in the Northern Hemisphere from west to east to continue the same, the complete disappearance of the Gulf Stream and all the ocean currents in the Atlantic would not have the slightest effect on the weather and climate of Europe, but any shifting of the anti-cyclone would—and every shifting always has had a corresponding effect upon both those conditions. And every considerable displacement of this vast atmospheric whirlpool produces far-reaching climatic phenomena, which are glibly attributed by the believers in meteorological mythology to "shifting of the Gulf Stream"; which very "shifting" itself is due in most instances to the action of the wind-currents of the anti-cyclone!

As those of my readers who are versed in the history of science well know, the "Father of the Gulf Stream" was the father of modern electrical science—the indefatigable journeyman-printer, philosopher, philanthropist, scientist, and statesman, who first drew down the lightning from the clouds along his damped kite-string—Benjamin Franklin. Thoroughly characteristic of that extraordinary man is the fact that in April, 1775, on his return voyage from London to Philadelphia, on which he was obliged to embark for his personal safety, after having received the most ruffianly insults from his aristocratic superiors of the mother country on attempting to negotiate the rights claimed by the New England colonists in their own taxation;—that man, who had then closely approached the limiting age of three-score years and ten, was seen day after day taking the temperature of the air, and then dipping his thermometer in the Atlantic, and scanning the record of the rise

or fall as eagerly as if no other object of earthly interest concerned him at the time. And equally characteristic is the fact that he had with him on board the velvet "Court suit" which he had worn on the special occasion on which he was admitted to the presence of the English Ministers in his function of representative of the New England colonists, and from which he was soon ejected with gross insult as a mere mechanic. That suit was carefully laid aside, and was again assumed—at an interval of eleven years—when the wearer, as Minister-Plenipotentiary of the newly-founded republic of the United States, attended in Paris to witness, in his then *inviolable* capacity, the signature of the same English Ministers to Great Britain's documentary recognition of the independence of the United States! On the voyage referred to, Benjamin Franklin gave the first practical demonstration of the fact that the thermometer could be used to determine the relationship of the voyager to the Gulf Stream, and thereby ascertain the longitude—which was more often guessed at than measured in those days; and which was of comforting importance when a trans-Atlantic excursion occupied a space of six to nine weeks.

Five years before that date Franklin had made, and had engraved for the benefit of navigators, the first chart of the Gulf Stream. But the sturdy British navigators would not look at it. When he arrived at Philadelphia he found that the battle of Lexington had been fought; and he proceeded to suppress his navigation charts as effectively as he could, so that they might not be utilised by the enemy. He had laid down the view that the permanent "trade winds" were the initial cause of the Gulf Stream; and, although partly in error, he was right in believing that the permanent aerial circulation in the North Atlantic is an important factor in determining the aqueous surface drift. His theory as to how winds form ocean currents is fully borne out by modern hydrographic research.

No special further enlightenment on the subject of the Gulf Stream was offered to the scientific world till the appearance of Maury's "Physical Geography of the Sea," in 1855. The theories of this justly famous writer soon attained the position of hydrographic orthodoxy. He made the Gulf Stream an argument for the proof of "design in the physical world." He opposed the idea of Franklin that the trade-winds were at all the cause of the Gulf Stream; maintained that "winds had little to do with aqueous currents," and wrote of the stream itself as "a sheet of warm water, said to be more than three thousand times greater than the Mississippi River," sent "entirely across the Atlantic Ocean." He proceeded to liken its effect on the climate of the British Isles to the heating of a house in winter by means of hot water, and told his readers that "one of the benign offices of the Gulf Stream is to carry heat from the Gulf of Mexico, where otherwise it would become excessive, and to disperse it in regions beyond the Atlantic for the amelioration of the climate of the British Isles and of all Western Europe." Such is the teaching which came to receive the stamp of orthodoxy! Maury knew nothing of the importance of the great anti-cyclonic circulation over the Atlantic Ocean. But its laws are very simple, and are now fully understood by the few. The whole general atmospheric circulation is determined by the expansion of the heated air

in the tropical region, which causes it to ascend and flow north and south to colder climes; and the resulting surface current in the opposite direction, which tends to restore the equilibrium so disturbed. The rotary movement of the subjacent earth from west to east also tends to produce atmospheric currents in the opposite direction. The permanent "trade-winds" represent the "resultant" motion derived from the composition of those two factors. Then the formation of a focus of low barometric pressure causes an inflow from all directions which leads to the production of the aerial whirlpool known as a *cyclone*; while the existence of an area of high pressure causes a spiral outflow towards all points of the circumference involved. The latter condition of the atmosphere is known as an *anti-cyclone*.

Let us now note that in the temperate zones the atmospheric drift is from west to east, which means that all coasts and countries that lie eastward of oceans possess climates ameliorated by oceanic influences, while the eastern parts of large bodies of land have climates affected by the masses of earth surface over which the aerial current has travelled; and we have the key of the whole climatic mystery. The great mid-Atlantic anti-cyclone practically covers the mid-Atlantic basin. Its pressure increases in summer and diminishes in winter. And its necessary movements to north and east determine the happy temperateness—frequently diluted with moisture, we must regretfully add—of the enviable climate of the British Isles.

ON CONTRACTILITY OF THE UNIMPREGNATED UTERUS.

By ALEXANDER DUKE, F.R.C.P.I.,

Late Assistant Physician, Rotunda Hospital, Dublin.

THE late Matthews Duncan says in his "Clinical Lectures" (page 133): "The sticky cervical mucus, as you are all aware, in 999 cases out of 1,000 hangs out of the uterus into the vagina, but I have seen it ascending and filling the cavity of the body of the uterus." This contractile function of the uterus, by drawing the cervical secretions *into* the cavity instead of expelling them, more especially when morbid and containing pus, tends to produce chronic, abnormal conditions of the uterus, and, I strongly suspect, of the Fallopian tubes.

I can quite imagine the uterus of a multiparous woman, more especially when subinvolved and compressed from above by loaded bowels, tight corsets, and perhaps full bladder in addition, acting somewhat like a rubber ball syringe, so that when pressure has been removed, a suction action is set up in the cervix, which draws up the secretions (morbid or otherwise) into the uterine cavity.

This suction action does actually occur during the act of impregnation, assisted by the return of the blood supply from the hyperæmic uterus after the sexual act, and I presume that a similar action may occur from various other causes, nervous or otherwise.

The uterine cavity thus charged over and over again leads me to think that some of the toxic symptoms developed in patients who have been vainly treated for rheumatism, suppressed gout,

&c., have arisen from this cause, combined, perhaps, with the absorption of morbid matter into the blood from fæcal lodgments and constipation in addition, and acting on this I have made inquiry as to uterine symptoms in patients I have been consulted about who suffered from stiff joints, painful at times, with pasty colour of face; and having treated the uterus alone have given relief to all reflex symptoms.

Uterine lameness is sometimes mistaken for rheumatism, and I think it advisable in such cases to make examination, and thus be enabled for *certain* to exclude or include the uterus as even a partial cause of the symptoms complained of. Cases are on record where a uterine stem has been drawn up into the uterus, button and all, while the converse is more commonly the case (expulsion of sea tangle or stem), due (in some cases, at least) to the fact that the tangle, tent or stem were *solid*, and while being introduced allowed of no exit for air or secretion, pushing both upwards, and setting up a contraction soon afterwards, which might act in either direction. For this reason *all stems should be either open from end to end, or grooved at side*, and the same applies to graduated solid "bougies," such as "Hegars," for procuring dilatation. My own impression is, that this contraction of the unimpregnated uterus, by the drawing in of morbid secretion, must eventually imperil the health of the tubes, and when such become patulous at the uterine end I can quite imagine some of the morbid matter with which the uterine cavity has been charged finds its way into the Fallopian tubes, and gives rise to pyosalpinx, &c., &c. So far as my experience goes, I consider that in those cases where secretion from the uterus is observed through the speculum, it is quite as important to secure free exit by drainage-tube or dilatation (or both) as to curette the cavity alone, and allow matters to resume their original condition some months afterwards.

Clinical Records.

DOUBLE PYOSALPINX. (a)

By J. INGLIS PARSONS, M.D., M.R.C.P.

MRS. B., æt. 35, a patient of Dr. Frye, was admitted on November 18th, 1904, complaining of severe pain in the abdomen which had confined her to bed for six weeks. She had been married twelve years, but had had no children or miscarriages. Her menstruation had been regular, but profuse, and accompanied by severe pain for a few days preceding the flow.

Six years ago she had a severe attack of pelvic inflammation with much pain. On examination, a hard, irregular tumour was found on both sides of the uterus. Temperature normal.

November 22nd.—On opening the abdomen the intestines were found adherent to, and almost covered by, two masses, one on each side of the uterus. After separating the intestines further inspection revealed enlarged tubes bound down by extensive adhesions matted to the uterus. These were removed with some difficulty but without rupture.

The patient made an uninterrupted recovery and left hospital three weeks after operation.

A CASE OF RUPTURED OVARIAN CYST. (b)

By GEORGE ELDER, M.D., &c.

MRS. B., æt. 50, was seen in consultation on Thurs-

(a) Specimen shown at the British Gynecological Society, January 12th, 1905.

(b) Notes read before the British Gynecological Society, January 12th, 1905.

day, November 3rd, 1904. Patient had a well-marked ovarian cystoma of the right side, reaching up to the umbilicus, and was advised to have an early operation performed. On the following Monday (November 7th) she came by train some twenty miles to a nursing home, where, in the evening, I saw, but did not examine her, as from her general appearance and absence of complaint, there was no reason to believe that the conditions had changed. Temperature same evening, 97.8°, and pulse 88.

Next morning, on being placed on the operating table, the prominence of the tumour was found to be replaced by a general flattening of the abdomen, and the fluid was diffused. On section, typically viscid, straw-coloured ovarian fluid poured out of the abdominal cavity, and on this being mopped out, the flaccid cyst was felt, resting on the right posterior wall, and was removed. As will be seen in the specimen, there are two small ruptures, and in other places the wall has been much thinned.

Subsequently, on questioning patient, she stated that on the Saturday evening she had some severe abdominal pain and sickness, which kept her in bed all Sunday, but did not seriously upset her general condition nor prevent her taking the railway journey on the Monday. The smallness of the openings would account for the fact that the rupture was not followed by shock, and the slight disturbance to her health was due to the benign character of the fluid. Some sudden distension of the cyst on Saturday evening, due probably to a slight twisting of the pedicle, may have caused the rupture.

My reason for bringing this specimen before the Society is that it not only illustrates one of the rarest and gravest accidents to which ovarian cystomata are liable, but also emphasises the opinion so often insisted upon before the Society, *viz.*, the importance of counselling immediate operation whenever a tumour of this nature is diagnosed.

Transactions of Societies.

BRITISH GYNÆCOLOGICAL SOCIETY.

ANNUAL GENERAL MEETING, JANUARY 12TH, 1905.

PROFESSOR JOHN W. TAYLOR, M.D., F.R.C.S.,
President, in the Chair.

THE Treasurer, Dr. Slimon, having presented his report and balance-sheet and the Editor of the *Journal* of the Society having read his report, and votes of thanks having been unanimously accorded to these officers, and also to the auditors, Dr. C. H. Bennett and Dr. F. A. Purcell, the election of the officers for the ensuing year was proceeded with. A complete list of those elected was published in our last number.

SPECIMENS.

Ruptured Ovarian Cyst.—In the unavoidable absence of the exhibitor, Dr. George Elder, his notes on this specimen were read by the secretary, Dr. AARONS, and will be found under "Clinical Records."

As Dr. Elder was not present the case was not discussed.

Dr. J. INGLIS PARSONS showed a specimen of "Double Pyosalpinx," an account of which will be found under "Clinical Records." He added that the points of interest were the symmetrical enlargement on each side, and the fact that the tubes had been got away without opening them. Those who had operated in such cases would know how difficult it sometimes was to do this when the intestines had been forming a sort of roof to the uterus and tubes, and one had to deal with dense adhesions. He began by separating the adhesions from underneath the back of the uterus, and in time both tubes came up successively, and could then be removed.

Dr. JERVOIS AARONS asked whether a diagnosis of double pyosalpinx had been made before operating on the case, or the blood examined for leucocytosis in view of the possibility of pus being present in the pelvic cavity.

Dr. ROBERT BELL said he had come across many cases of pyosalpinx, and all were bilateral and very easily removed. The specimens of one case he showed to the late Professor Joseph Coats, who, he believed, placed them in the Pathological Museum in the Western Infirmary, Glasgow. He had never met with adhesions in connection with pyosalpinx, nor found difficulty in their removal.

Dr. MACNAUGHTON-JONES said that his experience did not correspond with that of Dr. Bell. He had, again and again, found pyosalpinx with extensive adhesions, nor was their removal always easy. Indeed, some of the most difficult cases in gynecology were those of pyosalpinx, in which the tube was absolutely embedded in adhesions, with a plastic wall completely surrounding it. It was only when one broke through the wall that the pus in the tube was reached. Neither was pyosalpinx necessarily bilateral. Tuberculous pyosalpinx, for instance, frequently affected the tube on one side only. He had exhibited such a specimen before the Society, with a large pus sac, and the patient from whom he removed it had since borne three children.

Dr. HODGSON asked if Dr. Parsons had noticed whether the adhesions in pyosalpinx were much more extensive than in hydrosalpinx.

Dr. PARSONS, in reply, said the temperature in this case was normal while the patient was in hospital, and that was frequently the case. It was a very old case, and he believed the absence of fever was due to the fact that the system had become accustomed to the presence of the toxin. Probably the condition had existed before marriage, and was the cause why the patient had remained sterile for twelve years. He was willing to admit that he did not diagnose pyosalpinx before operation, as it was impossible to form an accurate opinion owing to tenderness on examination. He could not agree with his friend, Dr. Bell, about the absence of adhesions in pyosalpinx, but must concur with Dr. Macnaughton-Jones that such cases were sometimes the worst which gynecologists had to deal with. He would rather do a hysterectomy than operate upon some cases of pyosalpinx. The worst case of the kind he had seen was one in which he assisted one of his juniors at the operation. Both his colleagues were present, and they advised him not to proceed, but sew up the abdomen, which was accordingly done. In another case, a very bad one indeed, it was impossible to remove the sacs without leaving a large raw surface, and the patient died of intestinal obstruction some fourteen days after the operation. His experience was that one met with much worse adhesions in pyosalpinx than in hydrosalpinx; and it was sometimes most difficult to separate the bowel without tearing it, particularly if the case was recent.

The PRESIDENT then delivered his Valedictory Address, which will be found on page 75.

Dr. MACNAUGHTON-JONES said that on several occasions he had had to propose a vote of thanks to a retiring President, but had never done so with so much diffidence as on the present occasion. After the comprehensive summary of interesting and valuable work the President had given, he felt it a responsible task adequately to express the feelings of the Society, or attempt a due appreciation of that work. Professor Taylor had not been surpassed by any of his predecessors in the assiduity with which he had attended the meetings of the Society and directed its proceedings. The address just delivered was most suggestive, and would form one of the most valuable statistical records which had ever appeared in the *Journal*. One fact struck him particularly. During the last four years of his work Professor Taylor had performed thirty-six abdominal and twenty vaginal hysterectomies, fifty-six in all; and during the same period 320 operations of all kinds. As of that number fifty-six were hysterectomies, and among the whole 320 there had been but fourteen deaths, the low rate of mortality was a convincing proof of the merit of Professor Taylor's work. He was also struck by the fact that fifty-seven operations for extra-uterine pregnancy, and various complica-

tions associated with it, had been done, with only two deaths. Furthermore, thirty-eight cholecystotomies, including excisions of the gall-bladder, had been done, with only two deaths, and of the seventy-two vaginal hysterectomies in the table only two were fatal. The Society might congratulate itself on having had as one of its Presidents a man who could bring before it such a perfect record of surgical work. The President had recommended a valuable detail in practice which was too often neglected. Operating surgeons had necessarily to come into contact with septic influences, and make examinations involving septic infection, and he urged that, after contact with such septic conditions, they should always use a powerful antiseptic. This advice should be borne in mind by every operating gynecologist. Professor Taylor was the third President of the Society who had come from the Birmingham School, a school which must always hold a high place in the annals of gynecology. The most original obstetrician which the United Kingdom had produced was Simpson, of Edinburgh, but he would say unhesitatingly that Lawson Tait was the most original gynecologist that England had ever produced. Another familiar name which one was proud to see on the list of Honorary Fellows who had been associated with Birmingham in all minds since their student days was that of Savage. With these illustrious men Professor Taylor was fitly associated. No past President of the Society had more completely gained the esteem of its Fellows than had Professor Taylor; they wished him every success in his practice, long life, and every prosperity, and hoped that he, who had hardly reached the zenith of his fame, would on many future occasions grace their proceedings by his profound learning and vast experience.

Dr. HEYWOOD SMITH seconded the vote of thanks to Professor Taylor for his able address and for his conduct of the business of the Society during the past year. He cordially endorsed all the proposer of the resolution had said in appreciation of what the President had done during his term of office. His conduct, both on entering the Presidential chair and on leaving it, had been characterised by great courage. The Society would never forget the outspoken address with which he inaugurated his term of office, which had been referred to and quoted extensively by lay journals, and had started a discussion which ought to result in an improvement in the social morality and birth-rate in this and other countries. They were also extremely grateful for the address just delivered, and it was a great encouragement to the younger specialists in that branch of surgery that by similar earnestness and attention to details they might hope to emulate the President's success.

The motion having been carried by acclamation,

The PRESIDENT thanked the Fellows very warmly for the kindness which he had received since he was elected President. His year of office had been a very happy one, and he wished the Fellows a very successful and pleasant session under the Presidency of his esteemed successor, Dr. Alexander.

ULSTER MEDICAL SOCIETY.

THE Fourth General Meeting of this Society for the Session was held in the Medical Institute, Belfast, on Thursday evening, January 19th, the President, Dr. WILLIAM CALWELL, in the Chair.

Dr. W. B. MCQUILTY read notes of a case of General Paralysis of the Insane. The patient was a man, æt. 41, in whom the first symptom was transient diplopia fourteen years before, followed by lightning pains in the limbs two years later, which quite passed off. Nothing more was seen till shakiness of the legs began last year. Writing got shaky, he repeated his words, and speech and memory became affected. The special interest of the case was that it was a well-marked example of the spinal form of general paralysis, the earlier symptoms being those of tabes, showing the pathological identity of the two diseases.

PROFESSOR LINDSAY, in discussing the case, admitted the close relationship of the two diseases, but was not

prepared to go as far as Dr. McQuitty in regarding the pathological processes as identical.

Drs. McKisack and Graham also criticised the case.

Mr. A. B. MITCHELL showed a case operated on for Hare-Lip and Cleft Palate, and also an interesting case of Stricture of the Oesophagus. The latter patient had had a Symonds' tube *in situ* for six months, the passage of which was still patent. Mr. Mitchell emphasised the value of this treatment at an early stage, and expressed the opinion that the tube introduced should be of as large a size as possible—No. 18 or 20. Such patients are infinitely better than they would be after gastrostomy, for (1) they can still enjoy the taste of their food; (2) the tube acts as a drain to the oesophagus, and prevents the accumulation of food and secretions above the stricture; and (3) the discomfort of the abdominal opening is avoided.

Dr. H. L. MCKISACK read a short paper on the TREATMENT OF PNEUMONIA BY THE APPLICATION OF ICE EXTERNALLY,

which we shall publish in our next issue.

The paper was discussed by Professor Lindsay, Drs. Dempsey, McQuitty, Shaw, McIlwaine, Mitchell, and the President, and Dr. McKisack replied.

Dr. J. C. RANKIN read a paper on

RÖNTGEN-RAY TREATMENT,

and showed a number of illustrative cases.

Since taking charge of the new electric room at the Royal Victoria Hospital, Dr. Rankin had made 4,473 applications of the X-rays, and had treated 100 patients. Most of these patients had been under treatment of many sorts by many men, often for many years, the electric department being the happy dumping ground for all sorts of obstinate and unsatisfactory cases. The cases treated included 2 acne, 3 alopecia, 13 carcinoma, 10 rodent ulcer, 2 tinea tonsurans, 55 lupus vulgaris, 2 lupus erythematosus, 1 lichen planus, 10 sarcoma, 2 various. At first the time of exposure to the rays was 10 minutes at each sitting, but after a month or so this produced erythema, so the time was reduced to 5 minutes. None of the methods of estimating the strength of dose were quite satisfactory. In the lupus cases, for six months he had used the rays alone, and had got improvement, but after that time he removed the crusts and used an antiseptic dressing as well, and the improvement became much more marked. Not one of the lupus cases became any worse during the course of treatment, and many showed very marked improvement, as was shown by cases and photographs exhibited. Of the rodent ulcer cases some showed excellent results, but it remained to be seen if these were permanent. In the 13 carcinoma cases the results were disappointing, as also in the 10 sarcoma cases. For some time he had substituted radium for the X-rays, but it proved quite useless, and was given up. The paper was criticised by the President, and several other members of the staff of the Royal Victoria Hospital, who expressed their great sense of gratitude to Dr. Rankin for the immense amount of time and trouble he had expended in the establishment of this department, and in the treatment of cases sent to him.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, January 22nd, 1905.

THE COUGH IN PLEURISY.

PLEURISY, so rich in physical signs, is poor in functional troubles. The rigor which marks the *début* is not so intense as that characterising pneumonia; the stitch in the side is not very painful, dyspnoea is frequently wanting; expectoration is absent, and the temperature is usually moderate. It is thus that the pleuritic effusion is, in many cases, discovered by chance; sometimes it is only found *post-mortem*.

There is, however, one symptom which is sufficient to attract the attention of the medical attendant to the pleura—the cough.

The cough is a constant symptom of pleural effusions, be they secondary or primary, sero-fibrinous, hæmorrhagic, or purulent.

It does not exist in dry pleurisy; it appears only when a liquid exudes into the serous membrane. The cough is short and frequent, fatiguing the patient, and is followed by no expectoration. It does not come on without cause, but on the contrary, under well-defined circumstances. Immediately the patient stirs, either to turn in bed or to absorb a liquid, especially if it is cold, he is seized with the cough.

Péter attributes, with reason, this cough to irritation of the pneumogastric filaments. The pleural inflammation is transmitted to the intercostal and phrenic nerves provoking the pain. The liquid, becoming displaced when the patient stirs, strikes the regions above the level of the effusion and irritates the nerve filaments, thus provoking the cough by reflex action.

According to Milliau, every patient taken suddenly with a dry cough by a simple change of position is affected with pleurisy.

The attendant, bearing this precept in mind, can detect pleural effusion in a patient whose general condition is good, and who presents nothing else worthy of drawing attention to the respiratory organs; he can even detect at its *début* liquid in the pleura of a tuberculous patient.

Certain patients suffer also from a cough provoked by sudden changes of position, as those affected with vomica or bronchiectasis, but the cough differs from that of pleurisy by the fact that it is accompanied by expectoration.

The cough of pleurisy can be so harassing and painful that it constitutes the chief symptom of the malady, and necessitates treatment.

In mild cases, it is sufficient to advise absolute rest and silence, and the use of warm drinks. But more frequently active treatment is required and preparations of opium are indicated (laudanum, the black drop, or morphia). Inhalations of ether, frequently renewed by causing the patient to respire a plug of absorbent cotton wool wet with the liquid, is a good adjuvant to the opium preparation.

HÆMOPTYSIS.

Injections of 40 drops of a solution of adrenalin (1—1,000);

or Injections of gelatine, 1½ drachm to 10 ozs.;

or Hydrochlorate of hydrastinin, 2 gr.;
Water, 5 ozs.

A tablespoonful every hour;

or Hydrochlorate of hydrastinin, ½ gr.;
Hydrobromate of quinine, 1 gr.;
Ext. of belladonna, ½ gr.

For one pill, two daily;

or, Chloride of calcium, 1 drachm;
Laudanum, 30 min.;
Syrup of orange, 1 oz.;
Peppermint water, 4 ozs.

A tablespoonful every two hours.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, January 22nd, 1906.

At the Free Society of Surgeons, Hr. Croca reported THREE CASES OF PERFORATION OF THE STOMACH, or of the duodenum, that were presented at the hospital twelve to sixteen hours after the accident, and were all saved by operation. The first was a gun-shot perforation of the stomach; both entrance and exit wounds were united by suture. The second was one of ulcer in the lesser curvature; this was sutured and the abdominal cavity was afterwards thoroughly washed out. In the third case, perforation peritonitis had existed for sixteen hours; the yellow, odourless

contents of the abdominal cavity pointed to the duodenum, where the perforation was, in fact, found. The abdomen was drained in this case, notwithstanding which the symptoms subsided slowly. Pneumonia, which developed in the course of recovery, only retarded it slightly.

Hr. Dirk spoke on

MORPHIA-HYOSCINE NARCOSIS.

After some experiments made for the purpose of feeling the way, they had arrived at a method of giving these anaesthetics in Rotter's department. A solution of 0.001 grm. of hyoscine and 0.002 of morphia were divided equally in two syringes, of which one was given two hours the second one hour before an operation. In twelve patients one syringeful was sufficient; twenty-one required three syringefuls, but the majority (227) were given two in the manner described.

After the first syringeful a tired feeling and a tendency to sleep came on, but the patient woke up on being called to; after the second dose, they were prepared for the operation, were placed on the table, the skin disinfected, &c. The eyes were still open, but the patients were not properly conscious of their situation, and most of them had afterwards no recollection of what had been done. A few whiffs of ether or chloroform were then sufficient to bring about insensibility without any stage of excitement. In twenty-nine cases no further anaesthetic was required. After the injection the pupils were generally somewhat dilated, the pulse was from 70 to 90, the respirations were deep and there was slight cyanosis. The drying-up action of the hyoscine prevented tracheal rattling. Collapse or asphyxia were never seen. In the case of very deep narcosis, Cheyne-Stokes respiration was often observed, or a marked diminution of the frequency of respiration. After the narcosis, a sleep of from five to eight hours followed, out of which the patient awoke feeling well and without any recollection. Retching and vomiting hardly ever occurred, and no pneumonia followed in any case.

Three deaths took place, but all in cases of advanced carcinoma, the patients being respectively 76, 73, and 69 years of age. They were all very decrepit individuals, and they died some hours after the operation, without regaining consciousness. All the other cases bore the injections well. At the same time the rule should be laid down that when pronounced somnolence, pupillary stasis, and cyanosis come on after the first injection, the second should not be given.

A great advantage of this form of narcosis was its humane character, by which all excitement was avoided, its calm course, the nominal employment of the usual anaesthetics, and the fact that when the patients first awakened out of it the first pain from the wound had already passed off, and, lastly, the absence of nausea and vomiting. The drawback was the circumstantiality attending it, and the necessity of watching the patients for several hours afterwards in order to prevent the falling of the jaw and the sinking backward of the tongue.

Hr. J. Israel, on the whole, confirmed the representation of the speaker. He had employed the method in 332 narcoses, and had given at most 0.0004 grm. of hyoscine and 0.002 of morphia, but he acknowledged that it would be better to give it at two intervals. It was some drawback that when a series of operations were to be performed, the exact time for the later ones could not be predicted, so that the hour for the injection could not be fixed. In long operations it was an advantage that a little ether or chloroform be used. In thirty-two cases no ether or chloroform was given. The operations were all serious ones. The psychic factor must not be undervalued; the patient sank quietly off to sleep without being disturbed by any preparations. The extreme difference of action even from the same preparation was a disagreeable feature. This was observable both before and after the operation.

He had had three fatal cases. The first died before the commencement of the operation, but the case was one of anuria of a week's duration, which possibly

explained the fatal result. The other two cases were both young men who for two and three days respectively had been in a state of great excitement after the operation, with very frequent pulse; both died in a state of coma. The autopsy showed in both such a state of fatty degeneration of heart, liver, and kidneys as one only saw in phosphorus poisoning, although in neither case could there be any question of such intoxication. How far the hyoscine caused this could not be determined. The point required further observation.

Hr. Rotter did not think it necessary to wait two hours after the first injection for the operation, the action lasted much longer. The uneven action depended on individuality and not on the drug.

A NEW REMEDY FOR LEUCORRHOEA.

Dr. F. Knapp, of Berlin, strongly recommends the use of this new remedy, which has been introduced under the name of leucrol. It is sold in the form of pastilles, of which five are to be taken in the day, or it may be got in the form of a fluid extract. The feature of the remedy is that no local treatment is required. The leucorrhoea must not be of a gonorrhoeal nature. Two cases of simple colpitis are reported in which the remedy seems to have done good, one being cured after taking 95 pastilles.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, January 22nd, 1905.

OSTEO-MYELITIS TIBIÆ.

At the Gesellschaft Neudorfer showed a patient on whom he had operated for osteo-myelitis of the tibia, where a fistula had existed for a long time. The Röntgen rays showed a sequestrum in the bony canal close above the epiphysial line. The wound was freely opened, sequestrum removed, and granulation, according to Goldmann's operation, induced by a lateral flap with the pedicle above the wound, which rapidly healed, while the newly-denuded surface, by the removal of the flap, was treated according to Thiersch, by transplantation. After firmly binding all together, the wound healed by first intention, with a perfect functional result.

THERAPY OF ARTICULAR TUBERCULOSIS.

This subject has excited a good deal of discussion since Mosetig propounded his method of plumbung. In renewing the discussion, Spitzmüller said that he had had 144 carious cases in the Children's Hospital within the last four years, 22 of which he had treated according to Mosetig's method, with the happiest results. He had not selected the best cases in these experiments, as he had some misgivings in his mind when he commenced that the treatment would not be successful. On this account he selected for the experiments those cases which he had finally set aside for amputation. With this experience he could confidently assure the members that he spoke with no bias or prejudice in the results that he had obtained. The first case he showed was a patient on whom he applied the "iodoform-plombe" as a temporary measure. Another case was a severe form of caries in a child, æt. 11. The left foot was quite beyond recognition as such, penetrated with six fistulae, all ending on bare diseased bone, and emitting a most offensive discharge. The right foot was a mass of fungoid caries in the metatarsus and phalanx of the great toe, necrotic condition of the talus, calcaneum, navicular cuboid, and cuneiform bones, with destructive tuberculous changes in the capsule of the tibia. The whole of the morbid centres were "plombiret," and speedily took on a healthy condition without showing any signs of reaction, which, he contended, was strong proof that the "plombiring" was easily borne by the patient. One hundred days after commencement of this treatment the child was running about without any assistance from crutches or supports. In hospitals poorly endowed, where the necessary material could not be provided, he proposed a rubbing out of the cavities

with a dry, sterilised gauze and then dusting with iodoform.

Lorenz, in supporting Mosevig's treatment said that the "apparatio-therapie" was rapidly falling into disfavour. In coxitis, for example, where the patient has to lie for years and the function of the limb is destroyed before healing is accomplished, nothing is left for him but wearing a support or becoming the slave of the crutch. If we could so combine such a treatment as Mosevig's with the old form of "apparatio-therapie," a great advance would be made in surgery. Unhappily for the treatment the hip-joint has no indication for the use of the "iodoform-plombe."

Bardenheuer gave it as his opinion that the radical cure of hip disease was better treated by extirpating without opening the capsule. In his own private practice, since 1890, he had treated 545 cases of coxitis. Of these 94.8 per cent. recovered without any operative interference, and 63.6 without any pus formation. He thought he was within the mark in affirming that 50 per cent. of all such cases could be healed without expecting any purulent accumulation, and as long as no pus formed he was of opinion that no surgical interference should be undertaken. In his own cases, 31.2 per cent. recovered without any assistance or formation of matter. In old chronic cases where surgery is imperative, he prefers "onkarthrectomu," which really belongs to the category of freely opening up the abscess, removing all necrotic matter, and dressing with tampons to hasten a radical cure. The operation of the future, he thinks, in synovial tuberculosis is the entire extirpation of the capsule or, in other words, arthrectomia synovialis.

Eiselsberg said that Mosevig had obtained a success in this form of treatment which no others could lay claim to, and if his favourable results can be established the treatment would become classic. Tuberculous joints have been troublesome to all our noted surgeons such as Volkmann, Billroth, and König, who were all in favour of removing the tuberculous joint as a fundamental principle of surgery. The new expression of "knochenplombe" was not a happy one, as "plombe" was to stop and leave permanently. The present treatment is to renew the stopping or dressing in the bone frequently and thus induce a healthy surface, while regularly cleaning out the infectious or dangerous matter that tends to spread and finally destroys the joint.

The Operating Theatres.

BURFORD COTTAGE HOSPITAL.

SQUAMOUS EPITHELIOMA OF THE MUCOUS MEMBRANE OF THE LIP.—Mr. LENTHAL CHEATLE was asked to operate on a case of squamous epithelioma of the mucous membrane of the lower lip. The disease lay between the centre of the lip and the angle of the mouth, and was quite superficial; there were no enlarged glands in the submental region or at the angle of the jaw. Mr. Cheatle said he based his operation on the observations he brought forward at the Pathological Society in 1902, when he showed that squamous epithelioma beginning at the angle of the mouth or on the lower or upper lip progressed by involving the region occupied by the orbicularis oris, buccinator, depressor anguli oris, depressor labii inferioris, levator anguli oris, levator labii superioris, and levator labii superioris alaque nasi. The area affected also corresponds to the naso-labial nerve region of Dr. Head. Realising, therefore, what the area of spread would be if left alone, he planned his incisions accordingly. Thus, instead of making his two incisions V-shaped, as in the ordinary way, he made them parallel, and in the direction of the limits of the depressor labii inferioris. These incisions were well wide of the growth and included a segment of the

muscular fibres of the orbicularis oris and nearly the whole of the depressor labii inferioris. From the lower border of the maxilla, the lower ends of these incisions were prolonged in a V shape to a point midway between the hyoid bone and the angle of the jaw; the submental lymphatic glands were removed and the flaps brought together in the usual way. Mr. Cheatle said that if the surgeon separates in his mind the local spread of a cancer in this region, and also in the tongue and around the anus, from the secondary deposit in the lymphatic glands, he will find that the region occupied corresponds to the distribution of the cutaneous muscles; therefore, knowing the regions in which a cancer of these parts spreads, he plans his incisions accordingly. He referred in proof of his words to his articles in the *British Medical Journal*, April 18th and December 12th, 1903. During the spread of a cancer, he said, there can be no doubt that the spread of the primary growth often increases in one direction, and remains limited (possibly only temporarily, but for a considerable time) in other parts. If sections are cut at a part where arrest of growth has occurred, no difference in microscopical appearances can be seen to differentiate it from the spreading edge. There must be, therefore, some other than mere mechanical influence at work to cause even this temporary arrest. In the articles above referred to he stated that this is probably a nerve and trophic influence, a probability supported by the fact that rodent ulcers do not spread in completely denervated areas. Another point he wished to emphasise was, that if a cell or cells separate in cancer and hence become secondary deposits, they are under the trophic influences of the part into which they accidentally trespass. Mr. Cheatle had been referring in his words to the spread of the primary growth.

ROYAL EAR HOSPITAL.

OPERATION FOR RELIEF OF SUPPURATIVE DISEASE OF THE LABYRINTH.—Mr. RICHARD LAKE operated on a man, æt. 49, whose history was as follows: When æt. about 15, he received a kick from a pony on the left side of the face just below the zygomatic ridge; there was no open wound, but he states that some blood came from the mouth or from the ear. Six years after, whilst serving in India, he suddenly had a discharge of blood from the left ear; there was no pain, but he subsequently found his hearing slightly impaired. Two years ago something formed in his left ear accompanied by slight pain, and he states that "something" was removed from the ear by a surgeon. Three months ago he became giddy and suffered from tinnitus and vomiting, and subsequently he began to stumble and fall on his right side. The man was anæsthetised and the head shaved for an area of three inches round the left ear; an incision was made commencing just above the left ear in front and carried along through the edge of the hairy scalp, but curved forward inferiorly to the tip of the mastoid process; the incision was carried down to the bone all except the upper third, where the superficial tissues were alone reflected till the lower edge of the temporal fascia was reached. All tissues below this line and in front of the remainder of the incision, including the periosteum, were pushed forward until the whole of the posterior half of the external bony meatus was exposed, the cartilaginous meatus was separated

from its attachment to bone, exposing a large mass of granulation tissue practically occluding the canal. The membranous meatus was divided longitudinally in the middle line above and below, up to the edge of the concha. A piece of sterilised bandage was now passed through the external meatus and used to keep the ear drawn forwards for the remainder of the operation. The bleeding from all parts of the cut surface was very free, and took some time to get under control. The bone was now removed with a special gouge invented by the operator. In the course of a short time the antrum was reached. The next stage of the operation was the removal of that part of the bone lying between the antrum and the external meatus known as the bridge. The posterior wall of the external meatus was removed from without inwards by the chisel, as much of the external wall of the attic as necessary was next taken away. There was considerable oozing from the surrounding tissues, especially after the tympanum and adjacent parts had been thoroughly curetted. It was now necessary to plug the wound for a short time in order to thoroughly inspect that part of the field of operation where a lesion was expected, that is to say, in some part of the course of the external semi-circular canal. On removing the strip of gauze with which the cavity had been plugged in that situation normally occupied by the bony protuberance of the external semi-circular canal, a small sausage-shaped fleshy growth was found, roughly about $\frac{1}{3}$ inch in breadth and $\frac{3}{8}$ inch long, that occupied both as regards size and shape the protuberance just alluded to. On removing this with a small curette a little orifice was seen entering the bone at either end, these orifices being the continuance of the semi-circular canal. With the electric burr the remainder of the external canal was cut away up to, but without entering, the vestibule. The small flap made by the posterior wall of the meatus was now attached to the back of the posterior auricular flap by two or three sutures. The ear was sponged with Lister's strong solution, and plugged with a strip of antiseptic gauze, the end being brought out through the external meatus, and the wound entirely closed with sutures. Mr. Lake said that it was only of recent years that the enormous importance of suppurative disease of the labyrinth had been recognised at all, and for a much shorter space of time had it been considered possible to afford relief by operation. In the present case the patient's symptoms which pointed directly to labyrinthine disease were vertigo and sickness, and the fact that he fell towards the sound side. Mr. Lake considered this to indicate a destruction of the physiological properties of the canal, whereas irritation caused by suppuration within the canal would be more likely to cause falling towards the side of the lesion. He pointed out that he had removed the remainder of the semi-circular canal in order to get into healthy tissue, but as there was no sign of pus within the canal he did not enter the vestibule, for he believed that there was no necessity to enter the vestibule unless it was already the seat of disease. He said that some surgeons advocated entering the vestibule in cases such as this, but he thought it was very probable that in the cases in which prolonged giddiness had followed similar operations this was due to this casual treatment of the vestibule. His own view as to the correct treatment of such cases as the one just operated upon was, that it would be better to leave untouched the remains of the bony canal and to content oneself with a thorough removal of all granu-

lation tissue, together with a careful sterilisation of the cavity by means of Lister's strong solution, than to cut away parts of the labyrinth not yet physiologically defunct, unless the operator was prepared to remove the whole of the front wall of the vestibule in order to do away with the functions of the posterior half of the labyrinth. The importance of conservative surgery in operations performed for suppurative disease of the middle ear was not, he considered, sufficiently understood, and under ordinary conditions the removal of parts physiologically sound was bad surgery. It was more important to conduct the operation in such a way as to preserve all the parts of the internal ear which were not destroyed by disease. Finally, in such cases, he said, skin-grafting of the cavity was to be advocated on account of the great depth of the wound.

WEDNESDAY, JANUARY 25, 1905.

THE HOSPITAL FUNDS AND THE WESTERN SKIN HOSPITAL.

IN his last issue the editor of the *Hospital* maintains a discreet silence when pressed with various home questions as to the Funds and the sale of the site of the Royal Orthopædic Hospital. We regret this exceedingly, as he was practically the only mouthpiece of the Funds that has hitherto come in evidence with regard to our present series of articles. We had hoped that Sir Henry Burdett would have given us the views of the Hospital Sunday and King Edward's Funds with regard to the exclusion of Scotch diplomates from nine-tenths of the London hospitals. The Funds should certainly have a definitely declared policy upon this important point, for when they approved the amalgamation of the Royal with the National Orthopædic Hospital the exclusion of Scotch diplomates (waived for a limited period in favour of one particular individual) was made an essential condition by the National Orthopædic authorities. What has Mr. Martin to say to that? As chairman of the National Orthopædic Hospital, he would be fully informed upon the point, and as honorary secretary of the Hospital Sunday Fund he would have every opportunity of acquiring and of imparting full information to his fellow councillors. The presence of Mr. Martin in this dual capacity we consider renders the necessity of a

public investigation of the circumstances attending the sale of the Royal Orthopædic Hospital more imperative than ever. Mr. Martin would naturally welcome the £40,000 which the Royal Orthopædic would bring to the funds of the Royal National. The committee of the Royal Orthopædic would eagerly grasp at amalgamation as a means of evading unpleasant criticism, and to cloak the financial disaster consequent on the senseless sale of their magnificent freehold site in Oxford Street. As an *ex officio* member of the Distribution Committee of the Sunday Fund, Mr. Martin's presence may or may not explain to some extent the policy of that Fund in regard to the Royal Orthopædic Hospital. At the least, we regard his dual capacity as unfortunate. How has Mr. Martin's influence been used with regard to the City Orthopædic, which so far has maintained a sturdy independence of the Funds and resolved to avoid amalgamation? Doubtless his hospital, the National, would welcome the influx of another £4,000, even at the expense of one or two Scotch graduates. We will for the time being leave this question and turn to a hospital that has been persistently refused awards by the Hospital Sunday and the King Edward's Funds. We refer to the Western Skin Hospital, of Great Portland Street, London. This institution is one of the oldest special hospitals in the world. Fifty years ago it was founded as a pioneer in the study of diseases of the skin, long before any special departments were dreamt of in the large general hospitals. During the half-century of its existence this small hospital has carried on its work with humble and unassuming earnestness. Its income at the present moment does not exceed £400 per annum, and the absolute economy of its management may be gauged from the fact that the small sum mentioned provides for an average of 8,000 to 9,000 attendances of patients. To a long career and to unceasing economy of management may be added an honourable history. During the fifty years of its existence no breath of scandal has ever been connected with the hospital. Another skin hospital, which has been the object of repeated and unanswered public charges of the gravest nature, has received, and still receives, substantial grants from the Sunday and the King Edward's Funds. Why is the Western Skin Hospital sent empty away? Years ago its application for a grant from the Sunday Fund was met with a request to submit accounts on a different plan. That was done, and next year a member of the medical staff appeared before the Distribution Committee. He was told to apply again next year, and did so, but without the desired result. A year or two later another member of the medical staff appeared before the same committee at the Mansion House, and was advised by the chairman to attach himself to a better hospital. The details of these visits are doubtless recorded in the minute-books of the Sunday Fund Distribution Committee. The delegate who met with this rebuff reported to the Committee of the Western Skin Hospital, which, as

a self-respecting body, has naturally since declined to apply further to the Sunday Fund. The absolute honour, financial and otherwise, that controls the administration of the hospital is testified by the fact that for a great many years the treasurer has been Dr. Prosser James, formerly lecturer at the London Hospital Medical School. On his retiring a year ago he was succeeded by the Hon. Harry Lawson, M.P. If the Hospital Sunday and King Edward's Funds persist in casting so unmerited a slur upon the Western Skin Hospital, we think that the public have a right to ask on what grounds a grant is refused to that institution. If the two Funds mentioned are right in their action, then the Metropolitan Saturday Fund is wrong, for the latter has for years past made an annual award to the Western Skin Hospital. This recognition by the Saturday Fund is significant, as by its system of representatives from the class benefited by hospitals we have direct approval by those who have had an opportunity of testing the work of the particular hospital in question. The plain and definite question we put to the Sunday and the King Edward's Funds is, "Why do you refuse a grant to a small, struggling special hospital which presents a long and honourable record of charitable and scientific work, which is managed with absolute and unflinching economy, which is associated with honourable names, and against which the voice of calumny has never been raised?" Perhaps Sir Henry Burdett will answer on behalf of the Hospital Sunday and the King Edward's Funds. It seems hardly likely that the public which finds the money for the Funds would willingly lose the aid of a charity that does them so much service year by year. By this autocratic action of the Funds the Western Skin Hospital is condemned, as it were, by an irresponsible star-chamber system, without just trial. This, we feel sure, has only to be brought to the notice of King Edward to be promptly remedied.

THE PROBLEM OF THE ALIEN.

THE alien problem is a ripe theme for scientific as well as political discussion. Clearly it is a subject pregnant with vast medico-sociological factors which physicians and humanitarians generally should face with serious and analytical gaze. Our country has long been the refuge for outcasts from other countries. It may be freely admitted that no little benefit has accrued to us as a nation from the infusion of healthy, foreign blood in past years. Many of these settlers among us have been skilled of hand and active of brain, with vigorous bodies and well-trained minds, and their incoming has been of incalculable advantage. But at the present time, as every observant man well knows, our shores are being invaded by hordes of inefficients, many of whom are decadents in mind and body, deteriorates in morals, creatures that harass and hinder the evolution of the race. These degenerates through our out-patient departments, they gain entrance

to our hospitals, they grasp the charities established by our fathers, and we quietly nurse those who, biologically viewed, are literally drinking our life blood. It is quite unnecessary to furnish facts and figures to the medical mind. Every member of our London hospital staffs knows the appalling extent to which the burden of the alien is adding to the difficulties of the British benevolent. It is not for us either to suggest or advocate any particular form of legislative or other redress. We would, however, draw attention to one important point, a view ably brought out by Dr. Hyslop recently, in a discussion held by the Society for the Study of Inebriety, on "Alcohol in its Relation to Racial Degeneration." Dr. Hyslop clearly shows, and other observers have drawn attention to the same fact, that the British character is undergoing a remarkable psychological change, an alteration which in many of its aspects is of most serious import. With the urbanisation of the people and the spread of alcoholism and other habits detrimental to mental efficiency and physical progress, there is creeping over the country a hebetude and lassitude which impair resisting powers, and inhibit the natural protective mechanism. And there is some reason to believe that this parasitic spread of alienism is dependent in great measure on the lowered efficiency of our people, the diminished resisting power of our nation. Among a virile people the inefficient alien can gain no foothold. If the great hypothesis of Darwin contains anything of truth it is applicable in the present case. The survival of the fittest is still the demand of Nature, and this fitness is dependent upon powers of adaptation to environment. The alien, even when diseased and decadent, usually possesses immense powers of vitality. As every London physician well knows, the alien Jew of the East End, in spite of absence of nutritious food, with lack of almost every hygienic necessity, and even when heavily weighted by disease, often maintains himself in active competition with our own countrymen. The sad fact seems overwhelmingly true that among large numbers of our people there exist psycho-physiological states which readily permit of the encroachment of the alien, and oftentimes give to him a conspicuous advantage in the struggle for existence. The alien problem may be political, but it is none the less essentially biological.

THE DEWSBURY EPIDEMIC.

VACCINATIONISTS, anti-vaccinationists, advocates of the "Leicester method," sanitarians, and everybody who has regard for the decencies of life will do well to read the report made by Dr. S. W. Wheaton to the Local Government Board on the outbreak of small-pox at Dewsbury. This report discloses a state of things prevailing a few months ago in an English town, administered by self-elected representatives, that would be difficult to match with anything that occurred

in the chaos of the South African War medical arrangements. For stupidity, obstinacy, want of foresight, and super-abundance of red tape, we think that the story disclosed by Dr. Wheaton would not be easy to beat. Dewsbury for a long time past has been one of the anti-vaccinationist towns; not only have the Guardians been passive resistors to the Vaccination Acts, but at times they have been active resistors into the bargain, and vaccination had, in consequence, fallen to a low ebb at the beginning of last year. Now we should have thought that it behoved all honest anti-vaccinationists, if they determined on a policy of neglecting vaccination, to re-double their efforts to provide as complete machinery as possible for dealing with small-pox when cases did occur. This is the logical corollary to the anti-vaccination conviction. So long as small-pox is liable to break out, it will be necessary to fight it by vaccination or sanitary administration, or both. This point is thoroughly grasped by the authorities at Leicester—a town probably the worst vaccinated in the Kingdom—and so complete are their arrangements, and so vigorous their administration, that the success they have attained in dealing with outbursts of small-pox has come to be used as an argument in favour of the "Leicester method," as opposed to vaccination. It may safely be said that there was not much suspicion of the Leicester or any other method about the proceedings at Dewsbury. Sheer neglect of obvious public duty alone could have brought about the discreditable muddle which Dr. Wheaton temperately but ruthlessly discloses to the Local Government Board and to the public. Small-pox having shown itself last spring in the Dewsbury district, the Local Government Board wrote to the Guardians in April, asking what steps they proposed to take to secure vaccination and re-vaccination of the population, only, however, to receive in reply a communication from those wiseacres saying that they did not think it expedient or necessary to take any steps. As the outbreak continued, the Local Government Board wrote again in September, urging that vaccination stations should be opened, and being evidently dissatisfied with the information that came to them, very properly sent Dr. Wheaton down to investigate and report on the condition of affairs. We can best give an idea of what he found by quoting, as far as possible, his own words. The town small-pox hospital was situated in a corner of the cemetery; it was surrounded on three sides by an open rail fence, the side facing the cemetery being entirely unguarded. "Hence a particular patient found no difficulty in escaping at night-time from the hospital, with the result that he was discovered at his home having supper with his relatives." Nor can much blame be attributed to the patient. "The hospital consisted in a collection of small galvanised iron buildings and had a very dilapidated and forbidding appearance; nearly all the windows were broken, the apertures having

been stuffed with paper or rags. . . A foetid smell was noticeable outside the hospital, and heaps of refuse and partially consumed food lay around it, on which starlings and other birds were feeding." "On entering the building the foetor was extreme; the wards were much overcrowded, and were pervaded by flies, which arose in swarms from the patients when disturbed. The interior of the wards were very dirty, particularly the floors of the water-closets, which were of wood boarding." Cases from the surrounding districts were being admitted in the town hospital at this time, but owing to a fire destroying some extra buildings in course of erection, the Council refused to admit any but their own cases, and the joint Hospital Board for the outlying districts having neglected to provide either a site or a hospital, although it had been in existence for eleven years, small-pox patients in those districts were left at their own homes. In the Ravensthorpe Urban District, on his second visit, Dr. Wheaton found fifty-two cases thus retained, the necessaries of life being carried to them by the Council's servants, many of whom had not been re-vaccinated. Needless to say, several of them were infected in turn. "Nurses had not been provided, and in many instances persons who were only just recovering from small-pox, and were quite unfit to be out of their beds, were attending relatives in the acute stage of the disease. . . . As a rule, the homes of Ravensthorpe are well furnished, and the people are well off in the material sense; but few dwellings have more than two bedrooms, and hence the conditions arising where several cases of small-pox had occurred in the same household were often such as would hardly be credited in a civilised country. . . . In one small bedroom in a particular dwelling I found three adults suffering from small-pox, one single woman, aged 25, in one bed; and two single men in another; another healthy woman slept at night in the same bed with the female above referred to as suffering from small-pox." We have not space to quote further, but would only remind our readers that we are not referring to an epidemic of plague in the Middle Ages, but to an outbreak of small-pox in a prosperous English town, in the year 1904. Dewsbury and its surrounding districts would seem to be egregious relics of barbarism dying hard before the advance of modern civilisation.

Notes on Current Topics.

Death Certification.

AN incident which is being widely canvassed by certain sections of the press calls attention once more to the unsatisfactory conditions of death certification in this country. A woman, subject to cataleptic seizures, was taken ill with some complaint, and after a time, during which she appears to have been medically attended, her death was reported to the doctor, who thereupon granted the usual certificate. An undertaker was called in, and he found the

body, stripped and lying in a cold room, covered only by a sheet. He proceeded to take measurements in the ordinary way, when he noticed some movement of the eyelids, and this being repeated, he proceeded to attempt to restore animation by friction and warmth. His efforts were soon successful, and the woman regained consciousness and movement, though her condition was one of considerable danger for some time owing to her exposure and mental distress. Before the news of her revival was communicated to him, the doctor had heard that the woman had been subjected to an assault by a thief not long before her death, and he promptly telephoned to the registrar to cancel the certificate till he had communicated with the coroner. While we are unable to believe that the woman would have been buried alive under any circumstances, the story throws into strong relief the necessity for a system of inspection and certification very different from that which holds at present. The fact that a death certificate is demanded by the State from medical attendants, and that the latter are bound to furnish it without fee or reward, and that they may rid themselves of all responsibility in the matter by inserting "as I am informed," is creditable to no civilised State that sets a value on the lives of its citizens and on the prevention of crime. A death-certificate should be a confidential document supplied to the registrar by the doctor in attendance as the result of a special visit made after death, and should carry with it an adequate fee for the service. Moreover, no death should be registered without such a certificate or a coroner's order. The continued acceptance by registrars of the statements of unskilled persons as to the death of relatives is little less than scandalous.

Syphilis in General Practice.

THE danger of contracting some specific disease is a risk run by the medical practitioner in whatever class of practice he or she may be engaged. In the great majority of instances the physician is fully aware of the danger, and active means are employed to prevent such accidents. It is in doubtful or latent cases of infectious disease that the greatest danger exists of inoculating others, and the question also arises of the influence exerted by inanimate objects, including food, in the spread of infection. The diagnosis of venereal affections and of syphilis in particular is not always a simple matter, for it is well known that the primary lesion may be apparently absent, or so insignificant as to escape ordinary observation. The case is, therefore, apt to be dismissed lightly only to return after a couple of months covered with a profuse secondary eruption. More puzzling still are the anomalous and transient cutaneous rashes occurring in the early secondary period, particularly in women. According to Dr. Horace Wilson (a) the infectivity of syphilis is not

(a) *Med. Times and Hosp. Gazette*, December 31st, 1904.

emphasised sufficiently to patients. He has tabulated a series of twenty cases occurring in his own private practice in which he traced infection, either by the usual method or through the handling of food-stuffs or utensils. It is not pleasant to contemplate the fact that two milkmen "went through the whole disease while doing their ordinary duties of lading and carrying round milk," or that others engaged in such occupations as stewardess, barmaid, grocer's boy, and waiter were suffering from a loathsome complaint the infectious nature of which was, perhaps, scarcely or not at all realised by the respective victims. Dr. Wilson pleads for the better education of students in syphilology, whereby accuracy of diagnosis will be the more ensured and the spread of the disease to some extent checked. Notification does not, at the present time, appear to be of much practical utility.

The Electro-Magnet in Eye Work.

OUR contemporary, the *Ophthalmoscope*, bids fair to touch high-water mark in the annals of special medical journalism. It announces that its next issue will contain three important original communications upon the electro-magnet in ophthalmic surgery by three of the greatest exponents of that invaluable means of removing splinters of metal from the eye-ball, namely, Professors Hirschberg, Haab and Snell. Professor Haab's article will be of particular interest, since he describes how the "giant magnet" should be employed. There are reasons for believing that some of the failures with this instrument are to be ascribed to ignorance of how to use it. Both Professors Hirschberg and Snell favour the employment of small instruments, the so-called hand magnets, worked either from the street main, when that source of energy is available, or otherwise from batteries or accumulators. That a young journal like the *Ophthalmoscope* should be able to arrange a symposium of this sort shows that its management is marked by well-directed purpose and energy. Speaking generally, we should imagine that enterprise of this quality may still find hidden treasures in the field of medical journalism.

Inquests in South-West London.

THE situation in which the medical men in South-West London find themselves with regard to Mr. Troutbeck, to say the least of it, continues strained. We notice that Dr. Freyberger is still being called in as an "expert" and that his testimony is frequently in conflict with that of the local doctor. At an inquest held at Lambeth last week on a goods-checker on the London and South-Western Railway, the medical man in attendance ascribed death to a carbuncle in the neck, which led to pneumonia and cardiac failure. Dr. Freyberger, who is still referred to in the daily press as the London County Council Pathologist, propounded the theory that the carbuncle was due to a scratch on the finger, and consequently the unedifying spectacle was presented

of the views of two medical men on an expert point being submitted to the arbitration of a coroner's jury. In the absence of full information, it is, of course, impossible to form a definite opinion as to which of the two views was the correct one, but it seems that this matter was eminently one for friendly consultation and agreement before the inquest, so that a clear and definite view might have been laid before the jury. In any case, we presume Dr. Freyberger did not deny that the carbuncle on the neck was the mediate cause of death. With an ingenuity worthy of a hair-splitting "expert," however, he appears to have preferred asserting his superior acumen by going back to the original scratch as the cause of death. His position in this case demonstrates to a nicety the average value of the expert pathologist's opinion compared with that of a common-sense experienced general practitioner. When, however, amicable relations are rendered difficult by such incidents as have taken place in the past, one cannot expect the wheels of the coroner's court to run smoothly, and it is obvious to the meaneast intelligence that, in consequence, the public good is not likely to be subserved in the way it should be.

Dried Milk.

UNTIL the vexed question of how cheap, fresh, trustworthy milk is to be supplied to dwellers in towns is finally settled, every means, however artificial, by which such milk can be obtained is worthy of attention. Although it would hardly be seriously proposed to feed the nation as a whole on dried milk, yet, in the absence of any guarantee with the dairyman's product, it seems likely that a sphere may be open to milk so treated which is at present occupied by less desirable substitutes. In the November and January numbers of *Public Health*, communications on the subject appear, and in the latter issue Dr. Priestley gives an encouraging account of experiments of his own and those of other people on the changes that take place in milk that is artificially dried. The method employed for the preparation of the milk is as follows:—Two upright cylinders heated to between 220° and 230° F. are arranged parallel to one another, and milk is poured into a narrow interval between them. The water in the milk is instantly evaporated, and the dried products are stripped off the cylinders with a knife, and made to pass through a sieve which ensures only a fine powder resulting. The whole process only takes half a minute. The powder thus obtained can be instantly converted into milk by the addition of hot water, and the fluid so formed is not only sterile, but indistinguishable from ordinary milk in taste, smell, and appearance. The only appreciable changes are a slight lowering of butter-fat, as tested by chemical methods, and a certain change in the casein which prevents it forming large clots when brought into contact with gastric juice. After all, however, the truest guarantee of the efficiency of a food is its power

to nourish, and Dr. Priestley quotes the experience of Dr. Magill, of New York, who fed 850 children on dried milk during four months last summer, Dr. Beaumont, of East Ham, and Dr. Dunn, of the Crèche, at Ilford, to show that the milk is well absorbed and appreciated by the tissues. The bacteriological purity of the milk is also shown by the fact that no cases of diarrhoea occurred in any of the children so fed. It would thus appear that milk prepared from dried residues is preferable for children to the sweetened and preserved milks that have been so popular among the poorer classes.

Small-pox Research in London.

OUR readers will remember that some time ago an application was made to the Metropolitan Asylums Board by the superintendent of their small-pox hospital at Joyce Green, Dr. Ricketts, to sanction certain experiments on animals. These experiments were necessary if advantage was to be taken of the wealth of clinical material in the hospital for the purpose of pathological and bacteriological research. One would naturally expect that such an application would have been cordially granted, more especially as there would be no expense attached, and the experiments and their conditions would be subject to Home Office regulations. Unfortunately, the antivivisectionists saw their opportunity, and offered violent opposition both on and off the Board. Every attempt was made to foil Dr. Ricketts' scientific curiosity, but we are glad to learn that after many months' debate the Board has at length decided in his favour. It is interesting to reflect that this Board spends the greater part of a million of money every year in its fight against infectious diseases, but it at the same time hesitates, on sentimental grounds, to permit those researches which may render such expenditure unnecessary.

Water-Divining.

IT may happen, and it is a consummation devoutly to be wished for, that the spread of scientific education will gradually permeate the minds of people with a beneficent desire for evidence before accepting for gospel the specious pretensions of persons who are interested in deceiving them. One of the hardest of beliefs is that in the water-diviner, the wise man of the country who is able to tell, by the oscillations of his rod, where water lies beneath the surface of the earth. From time to time one sees instances of local authorities employing these charlatans, and if by any chance water is hit upon as the result of their guesses, the result is trumpeted forth as an instance of their sagacity. Of the numerous failures that take place the employers are discreetly silent, and it is comforting to know that the Local Government Board auditors invariably disallow the fees paid to these charlatans. A sound knowledge of geology is a necessary antecedent to any certain prediction of the presence of water in any particular spot below the ground, and the fact of the existence of water is of such importance to public health

authorities that considerable expense in the matter of expert fees is justifiable under this head. In the columns of the *Times* we notice a correspondence has been going on from which it is evident that the belief in impostors who pretend to be able to find water dries as hard as the belief in modern miracles wrought by patent medicines and quack treatments. A strong, clear contribution, which emanated from the pen of Dr. Thresh, Medical Officer to the Essex County Council, ought to settle the controversy out of hand. Dr. Thresh says that he has seen large sums of money wasted by landowners in sinking wells in positions where any hydrologist could have said at once that water was unobtainable, and that as for the V-shaped twig, any person with a little practice can make it perform most mysterious gyrations, without any perceptible movement of the muscles. When movements of the twig actually do occur, Dr. Thresh attributes the phenomenon either to wilful trickery or "unconscious cerebration." It is reassuring to be reminded that medical practice is not the only sphere where the brazen-tongued charlatan is able to compete successfully with the men who have made a life-study of the principles of their profession, but we have some reason to hope that increase of accuracy of true knowledge may soon render these pretenders as much of an anachronism as muzzle-loading guns or wooden battleships.

A Case of Glanders.

IN the field of public health there are few subjects more interesting than that of the passage of diseases from animals to man, just as in the field of bacteriology the comparative susceptibility of different races of animals to different infections is a question of alluring interest. It is, therefore, of importance from every point of view that those rare cases of infection of man by such diseases as are more common among the lower animals should be recognised, the source of contagion traced, and, where possible, the pathology investigated. In a case of glanders reported by Dr. Stephenson, of Dunmore East, (a) both the clinical condition and the mode of infection are interesting. The first lesion was in the shape of hard swellings on the roof of the mouth, followed a few days later by swellings under the jaw. The disease through its whole course centred about the mouth and nose, and resembled closely the condition commonly observed in the horse; subcutaneous nodules appeared on the chest, abdomen, back and face. The entire illness lasted one month, terminating fatally, but, as far as could be made out, the lungs were not affected, and the temperature never rose above 101° F. The course of infection was at first difficult of discovery, but on investigation it was found that a horse on the farm where the patient lived had been treated two years previously for a disease which was undoubtedly glanders. The horse had recovered, and been sold, but some of the manure

(a) *Dub. Journ. of Med. Sciences*, January, 1905.

from his stable lay in a pit under fresher manure for the two years. It had first been disturbed a few days before the patient's illness occurred, and he, while working at its removal, was in the habit of picking his teeth with his nail. There is little doubt that he carried some of the infection from the old manure heap to his mouth during this process.

Dropsy and Salt.

THE studies of M. Widal into the relation that exists between the administration of salt and the occurrence of renal dropsy are deserving of attention, and should furnish a new line of guidance in the treatment of Bright's disease. In several cases of nephritis of different types M. Widal has noticed that, by increasing the quantity of salt given to the patient, œdema was produced or increased, while when salt was withheld œdema, dyspnoea and other symptoms rapidly disappeared. The explanation offered for this curious phenomenon is simple. In certain cases of Bright's disease the kidneys are unable to excrete the normal quantity of sodium chloride, and it is deposited in the tissues. Collecting in this position, it attracts water to itself, and dropsy results. In cases of renal dropsy then, by diminishing the supply of salt in the food, we are able gradually to reduce the quantity in the body below the level at which the kidneys are able to cope with it, and thereby to restore the saline equilibrium. Of course, the abstinence from salt is never to be absolute, but by forbidding the use of extra salt in cooking and as a condiment, one can often restore the proper equilibrium, and thereby put an end to the dangerous hydration which gives rise to œdema.

A Novel Experience.

A STORY as remarkable as any we have read—so remarkable, indeed, that we would be loath to give it credence were it not vouched for by two unimpeached scientific witnesses—is told by Dr. Sidis, of Harvard, and Dr. Goodhart, of Yale, in their book entitled "Multiple Personality," published last week. The story is that of a Mr. Hanna, an able and cultured Baptist minister of Connecticut, who had the misfortune some eight years ago to be thrown from a trap on to his head. He became unconscious and remained so for two hours, when he gradually came round and violently assaulted his attendants without apparent cause. When he had been calmed down, although apparently conscious, he could not talk, and his movements were purposeless and evidently not co-ordinated by intelligence. This condition lasted a long time, and then very gradually his powers one by one reasserted themselves. Mr. Hanna's sensations whilst in this condition were very remarkable. When he came round after the accident all memory of the past was blotted out, and he was conscious of nothing except of his own existence. He, indeed, started the whole of his conscious existence *de novo*, and had to go through all the stages of learning again as he did in infancy. Thus, on

waking first, he saw all objects around him in the same plane, the power of stereoscopic vision having gone. He would stretch out his hands to grasp trees on the opposite side of the road, and was quite nonplussed at being unable to discover behind the looking-glass the person whose face he had seen mirrored in the front. The arts of walking and talking he had to learn afresh, but they were more rapidly acquired than in childhood. Many of his mistakes were ridiculously naïve; for instance, he was astonished to see how a cart could be separated from a horse, and the phenomenon of a rider dismounting from a bicycle struck him as a kind of self-mutilation. Mr. Hanna not only lost all knowledge of persons, but all affection for his family and *fiancée*, and, still more remarkable perhaps, his knowledge of the relations of the sexes and the fact of death terminating life. Finally, however, full adult consciousness returned, and all the memories of the past were released, and blended in his new life. Fortunately he was then able to record all his extraordinary impressions of what had taken place since the accident.

Proposed Extension of the Rotunda Hospital, Dublin.

THE many medical men who at some period of their career have received clinical instruction in the wards of the Rotunda Hospital will doubtless learn with interest that the Board of the hospital has determined to add another wing to the existing building. The Rotunda Hospital possesses one of the most interesting histories and buildings of modern hospitals. Its foundation was foreshadowed by the opening of a house for the reception of poor lying-in women in Great George's Street, by Dr. Bartholomew Moss, the first Master of the hospital. Subsequently, the main block of the present building was erected, and was incorporated by Royal Charter. It received its first patient in 1757. Its generous founder expended the best years of his life, and almost his entire fortune in its foundation and died penniless. In 1771, a room and apparatus was ordered to be fitted up for lectures in midwifery and disorders incident to women and children. In 1785 the new Assembly Rooms were commenced. It was expected that they would prove a valuable source of income to the hospital, and this expectation was fulfilled. In 1813 the ground and premises "lying west of the parent hospital" were purchased from the trustees of the Richmond Asylum for the Blind, and out of the building was made an auxiliary hospital. This building was subsequently devoted entirely to beds for gynaecological diseases, in which capacity it was used until the opening of the new auxiliary hospital in 1896. It was then converted into a residency for students, for which purpose it is at present used. In 1890 the Governors decided to commence the erection of a new building to take the place of the old auxiliary hospital, which from its construction was unsuited for that purpose, and to provide much-needed accommodation for nurses.

This building was opened during the last year of the Mastership of Dr. W. J. Smyly, to whose exertions its erection was largely due. The additional building which has been decided upon is rendered necessary for the accommodation of maternity patients, who now number close on two thousand in the year. It will also contain additional accommodation for nurses and students, thereby rendering it possible to increase the numbers of both.

Arsenic in Urine.

THE presence of arsenic in the urine after administration of the drug is recognised as of constant occurrence, as it is by the kidneys that the greater part of it is excreted. It is not so generally known, however, that arsenic may be present in recognisable quantity in presumably healthy urine. That it may be regarded as a normal constituent of the urine of a large proportion of the population is nevertheless made clear by the investigations carried out by Mr. William Thomson. (a) He examined the urine of a large number of residents in the city of Manchester, and found arsenic in recognisable quantity present in every case. As many of the persons concerned were total abstainers, and there was apparently no pollution of food, the only source of the arsenic seemed to be the air. Further differential examination confirmed this hypothesis. A series of specimens of urine obtained from residents in various manufacturing towns was examined, and arsenic was found to be constantly present. On the other hand the urine of people living in the country was all but free of arsenic, and that of residents in peat-burning districts was entirely so. Examination of soot from a domestic chimney where coal was burnt showed large quantities of arsenic, and dust on the shelf of a shop in Leeds contained as much as a third of a grain of arsenic per pound. It is important to bear these facts in mind, as otherwise the unexpected discovery of arsenic in urinary analyses might lead to wrong conclusions.

Detention of Patients.

OWING to the publicity offered by a coroner's inquest, an untoward incident which occurred recently at St. Mary's Hospital has given rise to a good deal of comment. A man stated to have been suffering from acute bronchitis was admitted on the 6th of this month, and after four days' treatment he got up and insisted on dressing. The house-physician and resident medical officer did their best to persuade him to get back into bed, but the man was obdurate, and claimed the right to leave the institution. This he was allowed to do, and after wandering about the streets for some three hours, he found his way to the police station. The inspector rapidly came to the conclusion that the man was not in his right mind, and had him conveyed to Paddington Infirmary under an urgency Lunacy Act form. Three days afterwards the man died of pneu-

monia. Dr. Danford Thomas, who conducted the inquest, commented on the laxity of the administration of a hospital that would allow a delirious patient to get up, leave the institution, and wander at his own will about the streets, and intimated that he would write to the hospital authorities on the subject. It is always easy to be wise after the event, and we know well what would be said if a patient who was *compos mentis* were detained by force in a voluntary hospital when he was determined to leave if possible. But there must always be a certain discretionary power left with medical men in charge of patients, and though they have no statutory right to detain any patient not under the Lunacy Act, still they have the right of all good citizens to prevent another doing himself damage. In the present case the doctors in question did not consider the man mentally afflicted to a sufficient degree to warrant the use of force, but surely they could have withheld his clothes till his friends had been communicated with, and no one would have blamed them for not permitting a man in his night attire to go out into the streets. As events proved, the man's restlessness and obstinacy were part of his illness, and we should have thought this would have been the dominant idea in the minds of medical men experienced in acute febrile illnesses. In this case an error of judgment has been committed, and it is to be hoped that the Hospital authorities will gather wisdom from experience, and call in an experienced member of the honorary medical staff to advise in future cases of difficulty.

The "Live Burial" Scare.

THAT popular fiction die hard is a well-known maxim. Of all such myths that of premature burial is one of the most cruel, while at the same time it rests on no established foundation of ascertained fact. Some years ago the whole question was investigated and discussed by a scientific medical man in a little book published by Bailliere, of London, under the title "Premature Burial, Fact or Fiction?" He came to the conclusion that while the literature and hearsay evidence was enormous, yet on the other hand no single instance of incontrovertible proof of live burial existed. At the same time, he did not deny that under circumstances of hasty burial, as in time of cholera or on the battlefield a body might be buried while still alive. That the fact of death could not be ascertained by the careful examination of a skilled medical man is beyond belief. In the absence of scientific evidence of live burial, the birth of a society, engineered by medical men, to prevent such an occurrence, becomes a laughing-stock for all wise men. The faculty of correct observation and logical reasoning, however, is not always guaranteed by the possession of a medical degree or diploma. In the recent case where a woman was resuscitated after having been laid out for dead, it was shown that the certificate of death had been filled up by the medical attendant on the strength of the friends

(a) *Medical Chronicle*, December, 1904.

report. The fact that a person was not buried alive scarcely warrants the wholesale revival of a mischievous and foolish scare.

Medical Editors in Glass Houses.

AN article recently published in the columns of a medical contemporary severely criticised medical writers who noticed proprietary drugs or medicinal preparations. Now there is no doubt that many such articles are widely patronised by medical men throughout the United Kingdom. Secondly, the leading medical journals freely insert the advertisements of such preparations, provided that the formula is not kept a secret. That being so, it is not easy to see on what grounds a medical editor can cry "maranatha" to a medical man for explaining to his fellows what is the exact use and value of recognised proprietary drugs thus advertised. Does the editor wish to course with the hungry hounds of professional etiquette, and at the same time run with the lucrative hare? Here is indeed a dilemma. Either the journalistic coffers must famish, or the editorial voice be for ever stilled; for, to be consistent, if the advertisers' money be taken, his wares must be recognised and scientifically and accurately investigated and described. To insert whole-page advertisements of a certain preparation for years together at an enormous charge in a medical journal, and then to condemn a medical writer for dealing with them is indeed to play the Pharisee under a cloak of high standard professional ethics.

"Following" the Midwife.

THE attention of our readers may be called to an important letter in our correspondence columns from the pen of Dr. Ward Cousins. No one is more entitled to guide and direct the opinion of the medical profession in this matter than that gentleman. Considering the vital bearing of the Midwives Act upon the everyday practitioner, it is curious how little familiar he is for the most part with the new conditions set up by the Act. It would be interesting to learn the experiences of readers with regard to the Act.

PERSONAL.

HIS MAJESTY THE KING has been graciously pleased to accept a copy of the autobiography of Mr. Frederick J. Gant, just published.

THE late Mr. Joseph George Lambert, after making certain bequests, has left the residue of his estate, probably about £70,000, to King Edward's Hospital Fund for London.

AT a recent meeting of the Dornoch (Sutherlandshire) Town Council, Dr. Jas. MacLachlan was unanimously elected Provost of the Burgh, a rare distinction for a medical man in Scotland.

DR. ERNEST WHITE, who has just retired from the Medical Superintendency of the City of London Asylum after nearly eighteen years' tenure of office, was the recipient of an illuminated address and silver tea and coffee service from the members of the Visiting Committee.

ON the occasion of the opening of the new Public Health Laboratories next week at Manchester University, the honorary degree of D.Sc., will be conferred upon Professor Calmette, Lille University; Professor Perroncito, Turin University; Professor C. J. Salomonsen, Copenhagen University; and Captain Scott, of the *Discovery*.

DR. R. J. D'ARCY IRVINE has been appointed a Senior Medical Officer of the Medical Department of the Gold Coast Colony, and has assumed duty at Accra.

PROFESSOR BRYCE, who recently returned to Plymouth from the Malarial Investigation Commission, is reported to have said that the West Coast of Africa, under common-sense sanitary administration, could be made a health resort like Ias Palmas.

THE Board of Management for the Congrès Internationale de la Tuberculose, which sat on December 20th, 1904, with M. Hérard as President, will be under the distinguished patronage of M. E. Loubert, the honorary presidents being M. Casimir and Léon Bourgeois; the acting president, M. Hérard; Vice-Presidents, MM. Chauneau and Brouardel.

The Congress will be in two parts, M. Letulle acting as Secretary-General, aided by MM. Derecq, Sersirou, and Georges Bourgeois. M. Léon Petit will be responsible for the exhibition, fetes, and receptions of the Congress, and M. Pierre Masson has been elected treasurer.

Special Correspondence.

[FROM OUR OWN CORRESPONDENTS.]

SCOTLAND.

LEITH HOSPITAL.—The directors have appointed Dr. W. M. Stewart, who has retired from the acting staff on the completion of fifteen years' service as full surgeon, to be an honorary consulting surgeon to the institution. Mr. A. A. Scot Skiring, F.R.C.S.Ed., has been appointed surgeon to the hospital and Mr. Charles Heron Watson, F.R.C.S.Ed., assistant surgeon, *vice* Mr. Scot Skiring.

Dr. Alexander James has been elected medical officer to the Edinburgh Merchant Company, in room of the late Dr. A. Lockhart Gillespie.

OPENING OF THE GLASGOW WESTERN INFIRMARY DISPENSARY.—For some time the hospital accommodation of the city has been seriously taxed, so much so that at the present time several hundred patients are daily waiting for admission. A new wing is being added to the Victoria Infirmary and with the three hospitals recently erected by the Parish Council, which roughly accommodate two thousand patients, the pressing difficulty is in a fair way of being overcome. The new dispensary of the Western Infirmary was opened on Wednesday last by Lady Blythswood before a company assembled in the waiting-room, which holds over 400. Sir Matthew Arthur occupied the chair, and there were also present Lady Arthur, Sir Lauder Brunton, Sir John and Lady Primrose, Sir Hector Cameron, Principal Story, Dr. H. E. Clark, C.M.G., and others. Prayer being offered by Principal Story, the chairman said that, owing to the large increase of patients requiring treatment in the dispensary of the Western Infirmary, the Medical Committee, in 1892, had reported that the accommodation was inadequate. However, at that time, the Infirmary itself was in even greater need of extension, and so the dispensary had to wait. The fact that the patients were still increasing again forced the matter before the managers, and in 1897 they started a building fund. In response they found themselves with £24,000. Building operations were started in 1902. In 1892, the number of outdoor patients was 12,422, with 38,507 visits, while for last year there were 22,010 patients and 94,235 visits. There was thus a daily average attendance of about 300 patients. Attendance

at the Dispensary is now compulsory for students; and the accommodation for them in the new dispensary is very complete. The estimated cost of the dispensary is about £35,000, so that there still remains about £10,000 to be raised to clear off the debt. The Chairman then called upon Lady Blythwood to declare the building open. Sir Lauder Brunton, M.D., then addressed the meeting. He said he had been in connection with outdoor work at St. Bartholomew's Hospital for twenty-five years, and that during seven he had been seeing from 600 to 800 patients every week. This perfection in waiting-rooms, however, required a large sum of money. He thought that money thus spent would come back bearing fruit tenfold and a hundredfold. The comfort of the patient was increased, and also that of his friends, as he was perhaps saved a serious illness by having his ailment attended to in time. This, of course, lessened the time the patient had to lie up, and therefore gave a greater working power all round, and as the wealth of the country is proportional as the producing power of the people, the patients did not alone benefit by an institution such as this. He then said something besides all this requires to be done. Medicine was not sufficient for the treatment of babes; good food was required and especially good, pure, fresh milk. He wanted it to be possible for mothers to obtain this milk, and this could only be done by some system of inspection of not only city dairies, but also the farms from which the milk came. He also mentioned a National League which had been formed for the purpose of directing physical education and improvement, and commended it to those present.

BELFAST.

THE MILK SUPPLY.—During the past fortnight a lively wordy warfare has been carried on in the public press on this important topic, the leaders being the anonymous writer of an article on "Our Milk Supply" and Dr. Henry O'Neill, who has come forward as a sanitary reformer in the city and in the Municipal Council, of which he is a member. The chief point discussed has been the desirability or otherwise of the sterilisation of milk. Dr. O'Neill has done his best to promote the use of sterilised milk, and to establish a municipal supply of that beverage, but a good many medical men in the city have growing doubts of the advantages derived from its use, and wish to concentrate public effort on the reform of the dairies and proper inspection and control of the supply. The *Northern Whig*, in an exceedingly sensible article on the 21st inst., sums up the discussion and pronounces in favour of the latter view. As it says, it is impossible to sterilise the universe, or banish disease germs from the world, but we can at any rate attend to the laws of Nature and endeavour to obtain our food and drink pure.

THE SMALL-POX EPIDEMIC.—Fresh cases of small-pox continue to crop up every day or two in different parts of the city, and so far all attempts to stamp out the disease have proved unavailing. The civic authorities have issued placards calling attention to the prevalence of small-pox, and to the prime importance of vaccination. The Lisburn Board of Guardians have been much exercised over the question of accommodation for small-pox cases, and have been advised by the Local Government Board Inspector to obtain a loan and build a proper hospital for these cases. They seem rather unwilling to go to the expense, however, and one sapient guardian expressed the opinion that small-pox was not, after all, such a serious matter, as he heard of cases in Belfast which never went to any hospital at all. The matter has been adjourned for further inquiry.

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

STERILISATION OF CERTAIN DEGENERATES.
To the Editor of THE MEDICAL PRESS AND CIRCULAR.
 SIR,—In your issue of January 18th, "A Student of Sociology" asks me some questions. May I say that

a reply to anonymous critics always brings up to my mind Scott's couplet where he makes Dougal Dalgetty offer to fight his French opponent,

"If you'll only come from behind the door!"

Well, even if this modest correspondent will not come from "behind the door," I must try to reply. He asks, "What would be the fate of anyone who would sterilise a degenerate without the person's consent?" If he refers to his fate in another world, I cannot answer. If he refers to a terrestrial fate, I would reply—Nothing. Parliament never has, nor never will authorise the performance of any operation except hanging—upon any person. The law says any operation is an assault (see Stephens' "Digest of Criminal Law," 4th Ed., p. 148). There is no law empowering any person to perform ovariectomy, or to bring on an abortion in those suffering from kidney or heart disease. Notwithstanding this, if my critic can find time to read Clouston's 6th Edition on "Mental Diseases," p. 578, when treating of puerperal insanity, he will find Dr. Clouston saying: "I think that abortion should be resorted to if marked insanity comes on in the early stage of pregnancy. . . In the later months, too, premature labour should, I think, be induced." Here is an authority recommending the killing of children in the womb. I only assert that we should excise and ligature the Fallopian tubes. My proposal is evidently too mild! My critic, in his further remarks, deals with the future. I prefer to deal with the present. I have gone to great trouble to show that there were, on one day in 1901, no less than 177,995 mentally deranged persons in the United Kingdom; that of 117,274 lunatics, 48,800 were married or widowed; that of 60,721 idiots and imbeciles, 18,900 were married or widowed; that this is a bad stock to breed from; that we have 11,238 deaf, mostly deaf mutes; that we are annually spending about £20,000,000 upon degenerates; that we are allowing idiots, imbeciles, and lunatics to marry and to beget offspring; that we allow the insane, liberated from asylums, to resume marital condition; and the fact that while we limit the birth-rate of those best qualified to beget healthy offspring, we allow the most degenerate part of the nation to breed indefinitely. This, to some, may be quite correct. I do not agree.

My critic evidently holds in high regard the 670 members of the House of Commons and makes me tremble (!) by asking me to think of "their shouts of laughter," if a Bill to legalise sterilisation were introduced. Surely he has a higher opinion of M.P.'s than he asserts.

Some 2,000 males and females are sterilised by surgeons in England yearly. If my critic will do me the great honour to look into my monograph on "Proposed Sterilisation," he will find that I also call attention to our disgusting law which provides that children of fourteen and twelve can legally marry; that we allow syphilitics and other physical deteriorates to marry; that we make it illegal, for the healthy, in many occupations, to marry; and that a diseased person must either marry or pay if he refuse to marry the woman to whom he is engaged.

Will you allow me to add, sir, that I am more than tired—being one in general practice and not a mere specialist—of this correspondence with "students," and that I think they ought to work up this subject of degeneration before putting one to the trouble of reply.

I am, Sir, yours truly,
 ROBERT R. RENTOUL.

Liverpool.

HOSPITAL REFORM.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.
 SIR,—There is not the least doubt but that there is a good deal to be done before the hospital system of London is in a satisfactory state. Mr. Sewill's views are those of a good Conservative. We have begun this century in a spirit of reform. Our army, our navy, our system of education, our laws, &c., &c., are all being criticised and amended. Some suffer sadly

and have to bear the brunt of the changes and the consequences of the faults of others. As regards our hospitals, it is rather sad, but not surprising to see how Sir Henry Burdett and the Hon. Sydney Holland differ; how Bartholomew's and Sir Trevor Lawrence have somehow gone off the stage in a very quiet way; how the Hospital Sunday Fund and the King's Fund are in a kind of competition for public support; and how the hospitals are all devising new ways and means to get funds to keep them out of difficulties. What will be the end of it all is not very clear.

Hospitals are peculiar advertisements to reputation for those connected with them, both lay and professional. The committees and their chairmen, the medical elements of these charitable institutions, the nurses or sisterhoods and their duties, are influenced more or less by other sentiments and motives than those of charity—that is, the good of others. We want a little reform in this rather questionable spirit of push and advertising that for some years has prevailed in this country. It is well for Mr. Sewill and men like him not to think they know when they don't.

I am, Sir, yours truly,

REFORM.

"FOLLOWING" THE MIDWIFE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your remarks in THE MEDICAL PRESS AND CIRCULAR of last week upon the "unenviable notoriety of the doctor when called to assist a midwife and relieve her of the onus of a bad case which has been too long untreated," very correctly state the experience of many practitioners throughout England and Wales, who have often been summoned to poor women in a dangerous and sometimes hopeless condition through the ignorance and neglect of unqualified persons.

It is, however, a matter of great satisfaction to know that, by the salutary operation of the Midwives Act of 1902, this kind of "following the midwife" will soon be a thing of the past, and that incompetent and unqualified persons will no longer infest the homes of the poor parturient women of our country. There are already nearly 9,000 certified midwives admitted on the first Midwives Roll, and these women are permitted to undertake only normal labours, and that in every case presenting any unusual feature or any abnormality occurring during pregnancy, labour, or lying-in, they are bound to obtain the assistance of a registered medical practitioner. Their practice is surrounded by wholesome restrictions, and they are strictly prohibited by law from writing any certificate of still-birth, or any certificate of death, or any other form of medical certificate—a practice which has been carried on without any limitation by many ignorant women who have had the audacity to call themselves "midwives."

It is true that the Midwives Act of 1902 requires amendment in many details; still, we may anticipate with confidence that this imperfect enactment will bring about a great and salutary reform in the practice of midwifery throughout the country.

In conclusion, I beg to inform my professional friends who have not yet read the Act and the Rules framed by the Central Midwives' Board, that a copy may be obtained at a trifling cost from the secretary of the Board, 6, Suffolk Street, S.W.

I am, Sir, yours truly,

J. WARD COUSINS,

Representative of the R.C.S. on the Central Midwives Board.

January 23rd, 1905.

SCOTCH QUALIFICATIONS AND LONDON HOSPITALS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Personally, as an Englishman holding a Scotch diploma, I am deeply grateful to you for bringing forward this subject. The hospital men of London have, naturally enough, sought to keep a good thing to themselves by a trades unionism of the grossest nature. It is only in the small hospitals, which the

Sunday and the King Edward's Funds apparently want to put out of existence, that the Scotch diplomat has his chance. Now that a powerful association of Scotch diplomates has been formed there is every hope that the public will be fully informed as to the injustice going on in the hospitals supported by their money.

I am, Sir, yours truly,

NORTHERN SCALPEL.

Obituary.

DR. OWEN M. PRAEGER.

A PAINFUL sensation has been caused in Belfast by the sad, self-inflicted death of a well-known and much esteemed young medical man. Dr. Owen M. Praeger, who was resident physician in the fever hospital at the Union Workhouse, was, on the afternoon of January 16th, found lying on the bed in his room, dead, with a bottle which had contained prussic acid near him. The *post-mortem* examination made it quite clear that death was caused by poisoning. Dr. Praeger, who was thirty-one years of age, was a native of Holywood, co. Down, and a member of a family well known in Belfast in connection with literary and scientific pursuits. His uncle, Sir Robert Patterson, is a prominent man in Belfast life, and his brother is well-known in Dublin, where he holds a post at the National Library. Dr. Praeger was educated at Queen's College, Belfast, and took his degree about four years ago in the Royal University of Ireland. Since then he has been resident in the fever hospital, except that for some months last year he was on special duty at the small-pox hospital at Purdysburn. About a year and a half ago he lost one eye as the result of an accident, and it is suggested that his mind may have brooded over this, and the consequent disfigurement. He seemed, however, in excellent health and spirits, and no motive is known for the rash and sad act which terminated his career. He was a great favourite with all with whom he came in contact, and his tragic end is deeply regretted.

WILLIAM MOORE, M.B., C.M., GLASGOW, OF AYR.

The death is announced of Dr. William Moore, M.B., C.M., Medical Officer for Ayr, of pneumonia, after a brief illness on the 16th inst. A native of Newmilns, Dr. Moore first came to Ayr twenty-five years ago as house surgeon to the County Hospital. He graduated M.B. at Glasgow University in 1876. Besides a considerable private practice, Dr. Moore was Medical Officer for the Foresters' Friendly Society and held an appointment under the Factory Act. He was fifty-two years of age, and is survived by a widow and four children.

Literature.

WINGRAVE ON ADENOIDS. (a)

THE time is long past when it was necessary to adduce arguments to prove the existence and the harmful effects of post-nasal adenoid vegetations; indeed, most practitioners of the modern school are quite alive to the importance of diagnosing and removing the growths in question. This well-printed and otherwise commendable monograph gives a very clear idea of the condition and of the means of getting rid of the obstruction caused by the presence of the characteristic proliferation. An excellent idea of the *facies* of young subjects of respiratory obstruction, due to this cause, is conveyed by the photographs reproduced in illustration thereof, and the volume of the growths occasionally met with is testified to by the very telling photograph on the first page.

The principal question that the practitioner is called upon to decide is as to the propriety of operating in a given case, and opinions differ widely in respect of

(a) "Adenoids." By Wyatt Wingrave, M.D., Physician and Pathologist, Central London Throat and Ear Hospital. (Medical Monograph Series, No. 9.) London: Baillière, Tindall and Cox. 1904. Price 2s. 6d. net.

the degree of obstruction that may be held to justify operative interference. Certainly the mere presence in the naso-pharynx of a child of a certain amount of lymphoid over-growth, not attended by troublesome local or constitutional symptoms, is not of itself an indication for operation, and the author is careful to insist on the collateral conditions that render removal a matter of urgent necessity. The fact that in a certain proportion of cases masses of adenoids have virtually cleared up soon after the age of puberty, hardly affords sufficient reason for "waiting to see" in the majority. The author does well to point out that although a comparatively trifling operation, the removal of large adenoid masses is a very sanguinary, and sometimes a distressing, operation. The rough or inexperienced operator can do a great deal of harm in a short time, to say nothing of the risks inherent to general anæsthesia in these subjects.

Within the compass of this short monograph the author practically exhausts the subject, and has written a work worthy to rank with its predecessors in the series.

REPORTS OF THE TRYPANOSOMIASIS EXPEDITION. (a)

This volume consists of a series of reports of the investigations which have been carried on by the Liverpool School of Tropical Medicine into the subject of human trypanosomiasis in the Congo Free State. Some of the individual papers have already been published in various medical journals, but gathered together as they now are, they constitute a work of high scientific importance, and one of which the Liverpool School may be proud.

An expedition was first sent to the Congo from Liverpool in September, 1903, at the request of King Leopold, of Belgium, and as early as January, 1904, a report was published containing as its most important conclusions the statement (1) that the trypanosome found both in cases of simple trypanosomiasis and of sleeping sickness in the Congo was identical with the *Trypanosoma Gambiense*; and (2) that somnolence was a comparatively rare symptom of "sleeping sickness." At the time of this first progress report, 707 individuals had been examined. This number has been now increased to 1,172, and the extended experience has enabled the first conclusions to be amplified and confirmed both in Africa and, experimentally, in Liverpool. Some details of the clinical symptoms of trypanosomiasis are also given, and the disease is divided into three stages according to the severity of its manifestations; the last stages appear to correspond to what is known among the natives as "sleeping sickness." The writers point out that "in nearly every case in which sleeping sickness was diagnosed or suspected, trypanosomes have been found either in the blood, cerebro-spinal fluid, or both," but add the important statement that as yet there is not sufficient evidence to prove that death is produced by trypanosomes alone, and that in almost every fatal case, some secondary bacterial infection is found. The special report by Christy on the cerebro-spinal fluid in sleeping sickness is of great interest, and as far as it goes shows that the symptoms of the disease are not definitely related to the presence of trypanosomes in this fluid as distinct from their presence in the body generally.

In addition to the direct work on trypanosomes, the volume contains papers on the "Congo Floor Maggot," and on the "Tse-tse Flies." Both of these have been published before, and need not be referred to, further than to say that their inclusion in the present report is an evidence of the comprehensive manner in which the problems of tropical disease are now being attacked.

DISEASES OF WOMEN. (a)

THERE is a refreshing originality in the way the authors handle a subject which, until quite recently, was made up of a very small proportion of certain knowledge, embedded in an unlimited quantity of "dogmatic theory." To Mr. Bland-Sutton and to the late Mr. Lawson Tait we are indebted in great measure for the sweeping away of the ambiguities that hindered the study of gynecology. The result is seen in the severe cutting down of chapters on such subjects as uterine displacements, to which in years gone by an overweening amount of space was given, and the great extension given to the etiology, diagnosis, and treatment of diseases of the uterine adnexa, ectopic gestation, and cyst formation.

The present edition is in many ways an improvement on its predecessors. Various lapses have been remedied, and redundancies have been rigorously eliminated. It is now a practical treatise on gynecology, better fitted perchance for the practitioner than for the student, since the latter may meet at the examination-table specialists in this department who belong to another century, and who resent the substitution of the scalpel for time-honoured dilatory procedures.

We concur in the authors' view that "when surgical authors are able to restrain their vanity and refrain from publishing notes of successful cases in text-books, the established facts of the art can be presented in a very convenient compass." In some 500 pages of large and well-led type they have covered the whole ground, and this in a manner that, technically, leaves nothing to be desired. The literary style is at times a trifle rough. Why, for instance, do they use "superiorly" and "inferiorly" instead of the much more convenient and simpler terms, "above" and "below"? We miss many illustrations from former editions, their place, or that of some, being taken by new ones. One may question the value to the reader of illustrations of cysts, ruptured tubes, and the like, for they really convey no very clear idea of the actual specimens, and throw no particular light on the text—which, indeed, stands in little need of such elucidation. There are numerous well-thought-out tabular statements of points to be borne in mind in considering the diagnosis, and altogether the work is one which does credit even to such an able surgeon as Mr. Bland-Sutton, flanked by his talented coadjutor.

DISEASES OF THE EAR. (b)

IN these days when every surgeon who devotes his attention to a special region of the body finds himself obliged by force of example to write a book on his subject, it is hardly to be expected that each new volume will teem with original research or fresh information. Dr. Kerr Love's book, which we have before us, contains a plain, straightforward account of the anatomy, pathology, and diseases of the ear. In a book of this size we should have expected a somewhat fuller discussion of the details of some of the conditions than we actually find. For instance, the relation of ear disease to life assurance is dealt with in a simple page, and the ear complications of the infectious diseases are dismissed in a bare half-page. It is true that reference is made again to the latter subject latter on, but the information given is scrappy, and the statement that "the acute mastoiditis which follows scarlet fever is very amenable to surgical treatment," will hardly accord with the experience of many other aural surgeons, we fancy. The great value of the book, however, lies in the elaborate and beautifully-executed series of stereoscopic plates illustrating the anatomy of the temporal bone and auditory apparatus, together

(a) "The Diseases of Women: A Handbook for Students and Practitioners." By J. Bland-Sutton, F.R.C.S., and Arthur E. Giles, M.D., B.Sc. Lond., F.R.C.S. Ed., Surgeon to Out-Patients, Chelsea Hospital for Women, and Gynecologist to the Tottenham Hospital. Fourth Edition. London: Rebnan Ltd.

(b) "Diseases of the Ear." By James Kerr Love, M.D., Aural Surgeon, Glasgow Royal Infirmary. With Fifty-four Stereoscopic Photographs, Two Coloured Plates, and many Illustrations. Bristol: John Wright and Co. 25s. net.

(a) "Liverpool School of Tropical Medicine.—Memoir XIII. Reports of the Trypanosomiasis Expedition to the Congo, 1898-1904." By J. Everett Dutton, M.B., John I. Todd, M.D., and Cuthbert Christy, M.B. With a Comparison of the Trypanosomes of Uganda and the Congo, by H. W. Henslow, Thomas and Stanley Linton, and a Note on Tse-tse Flies, by E. E. Austin. London: Williams and Norgate.

with some of their diseases. The preparations from which the photographs were taken are excellent, and the fidelity of their reproduction irreproachable. Nothing more accurate or realistic than these plates is to be found in the annals of British aural surgery. It remains only to be said that the paper, printing, and general get-up of the book render it a veritable edition *de luxe*.

NORMAN WALKER'S DERMATOLOGY. (a)

THE appearance of the third edition of this popular handbook should serve to further stimulate the interest of practitioners and students in the somewhat unattractive sphere of skin diseases. The opinion that this work may be taken as "a concise and accurate guide" in the subject with which it deals, which we expressed concerning previous editions, remains unaltered to-day. Considering what a useful adjunct the X-Rays are to dermatological therapeutics, it is not surprising to find that a good deal of space is devoted to accounts of this comparatively new mode of treatment. The author is not prepared to recommend the rays as a routine treatment in ringworm of the scalp, but he has seen them produce a rapid disappearance of patches of psoriasis. This latter disease is considered to be an "extremely dry form of seborrhœa," an opinion which is not shared by the majority of dermatologists in this country, although it is true, of course, that there are many cases which seem to lie on the borderland between psoriasis and seborrhœa. The treatment of lupus occupies eight pages, and is very thoroughly dealt with. The effect of radium, especially upon patches upon the palate, is highly spoken of, and a brief reference is made to the possible therapeutic uses of uranium in this affection. The unusual course is still adopted of describing the *pediculus corporis* under the heading of "Anomalies of Circulation" as a purpuric manifestation. Without being too tied and bound to the slavery of classification, this book is eminently readable. The photographic illustrations are excellent, but we cannot say the same of the coloured plates.

BERRY ON SURGICAL DIAGNOSIS. (b)

THERE is as much difference between surgery taught in systematic treatises and actual diagnosis as there is between learning to read a language and trying to speak it. Moreover, the knowledge of anatomy and surgical pathology which medical students acquire is of use only so far as it enables them to arrive at a correct diagnosis as a preliminary to treatment. The diagnosis of abnormal conditions is, therefore, a subject in itself, and may advantageously receive special treatment. No excuse is needed consequently for this work, nor for the fact that the author makes no pretence to having covered the whole ground of surgical diagnosis.

Turning to the text we find that it really does not go beyond the principles and facts which every surgeon, old and young, must have in mind when he sets himself the task of deciding the nature, origin, and probable result of a given lesion. The first fact that the student has to grasp is that "all that glitters is not gold," and that things are often not what they seem. Nothing is more difficult to the beginner and the inexperienced than to keep an open mind until data sufficient to establish a diagnosis have been obtained, he is but too apt to "form an opinion" early in the course of his examination, and to allow that immature judgment to influence his subsequent steps.

The author endeavours to impress the reader with the necessity of having all the possible interpretations of a given group of symptoms present in the mind before deciding in favour of only one of them—this is "diagnosis by exclusion," the only safe method for general

use. Doubtless, many a student will remark how simple, how obvious are the points to which attention is directed, but the important thing is to have them before one in forming an idea of the significance of the various symptoms and physical signs. By restricting himself to the minor points the author has been enabled to keep the book of moderate dimensions.

The work will be of service to others than students. Many a practitioner will derive material assistance in obscure cases by looking up the directions given for the differential diagnosis. The author shows him how to obtain practical experience, although he cannot confer the *tactus eruditus*, charm he never so wisely. We feel confident that Mr. Berry's work will become popular by reason of its limitations and practical bearings.

LAMB'S EXAMINATION OF THE THROAT, NOSE, AND EAR. (a)

THIS is a book which we have long been looking for in vain. It has always surprised us that no one, until now, has written a short work on a subject of daily interest to practitioners. The author's aim has been to provide an extremely elementary handbook. A brief introduction describes the position of the examiner, and the use of the mirror or reflector. In the chapter on the examination of the pharynx the author gives a clear account of the anatomical points of importance. The mode of examination is accurately described, and the various abnormal conditions likely to be met with pointed out. In considering the examination of the nose, Dr. Lamb gives an excellent summary of the anatomy of this region, illustrated by a number of very practical diagrams. The method to be adopted in examining the nose is fully detailed, and the morbid changes likely to be present are described.

Personally, in teaching students we have found that the examination of the larynx usually presents the most difficulty. A study of the remarks made by the author and the hints which he gives will do much to simplify this process; although the reader must not content himself with the mere theory of the subject. The commoner affections of the larynx are considered somewhat briefly, but quite sufficiently for all practical purposes. The description given in the chapter on the examination of the ear, of the various tests usually employed for purposes of diagnosis is written in plain language which any average student can understand. The method of Politzerisation is briefly referred to, and the use of the Eustachian catheter is very fully described. Siegel's suction speculum and the aural conditions in which it is of special value as a diagnostic are mentioned. The chapter on local treatment is very readable, and bristles with most valuable therapeutic suggestions.

A careful perusal of this practical guide convinces us that it meets a much felt want. There are many cases occurring in every-day practice which remain undiagnosed simply because the practitioner has not had the advantage of training in the examination of the throat, nose and ear. By following out the directions given by Dr. Lamb no one of average intelligence can fail to succeed in carrying out the necessary examinations of these organs. We have seldom read so practical a guide on any subject connected with medical practice, and we have no hesitation in expressing the opinion that this small text-book will become a general favourite with senior students and practitioners.

Medical News.

The Laryngological Society of London.

At the annual meeting of this Society on the 13th inst., held at 20 Hanover Square, the following officers were duly elected to serve during 1905:—*President*: Charters J. Symonds, F.R.C.S. *Vice-Presidents*: W.

W. de Santi, F.R.C.S., and H. J. Davis, M.B., M.R.C.P.

A Dentistry Degree.

THE Court of the Manchester University last week unanimously approved a resolution, moved by Prof. Stirling, to put into effect the ordinances for degrees and diplomas in dentistry. Prof. Stirling explained that the scheme had been prepared by their dental colleagues, and carefully considered by the medical faculty at several meetings. It established degrees and diplomas in dentistry, thus removing from dental students in this part of the country the disability under which they had laboured in having to go to London to be examined. A dental student, before obtaining a licence to practise, would have to study for four years.

Congress of School Hygiene.

THE French Congress of School Hygiene will hold its second meeting at Paris in June, 1905. The following is the programme:—(1) The medical inspection of primary schools; (2) the education of families in school hygiene; (3) vacations and holidays; (4) tuberculosis and teachers; (5) the over-loading of school courses and competitions for admission to large schools. Professors Debove, Grancher, Landouzy, and Pinard are honorary presidents of the Congress. All communications should be addressed to Dr. I. Ch. Roux; 46 Rue de Grenelle, Paris.

International Congress of Obstetrics and Gynaecology.

THE fifth meeting of the International Congress of Obstetrics and Gynaecology is to be held at St. Petersburg from September 11th to 18th of the present year. The principal subjects proposed for discussion are (1) *Accouchement forcé*; (2) the operative treatment of fibro-myoma of the uterus; (3) vaginal methods of operation in obstetrics and gynaecology; (4) critical discussion of the operative procedures for retro-deviations of the uterus; (5) chorion-epithelioma.

International Congress of Psychology.

THE International Congress of Psychology holds its fifth meeting this year at Rome, April 26th to 30th. There will be four sections: Experimental Psychology, under Professor G. Fano, of Florence, will deal with psychology in its relations to anatomy and physiology, psycho-physics and comparative psychology. Introspective Psychology, under Professor R. Ardigò, of Padua, devotes itself to psychology in its relations to philosophical sciences. Pathological Psychology, under Professor E. Morselli, of Genoa, will discuss hypnotism, suggestion, and analogous phenomena, and psycho-therapeutics. Criminal, Pædagogic, and Social Psychology will be under the presidency of Professor Lombroso, of Turin. The official languages of the Congress are Italian, French, English, and German. The President of the Congress is Professor Giuseppe Sergi of Rome; the General Secretary Dr. Sante de Sanctis, to whom all communications should be addressed at the Instituto Fisiologico, 92 Via Depretis, Rome.

Is Leprosy Curable?

It is announced that treatment with leprolin, the new serum prepared by Captain Rost, I.M.S., is being tried in several of the Indian Asylums of the Mission to Lepers. At Purulia, in Bengal (where the Society supports 600 lepers), three cases are declared by the Deputy Sanitary Commissioner of the district to be "to all intents and purposes completely cured." Others show less favourable results. The hopeful cases will be isolated and observed for six months before a final decision can be pronounced. If found to be of lasting benefit, the Society will adopt the treatment in others of its forty-two asylums in India and the East. Meanwhile, it is hopeful to have Dr. Wilson (of Miraj, Bombay Presidency) saying, "There is no

doubt that Dr. Rost has made a very great discovery, and again opened the door of hope to the lepers."

Welfare Work.

ONE of the promising movements of modern times towards the moral, intellectual and physical betterment of employes is known by the name of Welfare Work. As a rule, a welfare manager is appointed. He is a recognised intermediary between employer and employed, and his exclusive duty is the improvement of the conditions of workers. Many great industrial concerns in America have joined this movement. Amongst English firms that have gained an international reputation for welfare work are Messrs. Cadbury Brothers, Ltd., Lever Brothers, Ltd., and Burroughs Wellcome and Co. In America, the National Cash Register Co. was the pioneer of all welfare work. A convention of Continental and district managers of the N.C.R. Co. is being held in London, and last week appropriately visited the Wellcome Club at Dartford, an institution provided by Mr. Henry S. Wellcome for the 1,200 employes of Burroughs Wellcome and Co., the wholesale druggists.

PASS LISTS.

Royal College of Surgeons of England.

THE following, having passed the necessary examinations, and conformed to the by-laws and regulations, have been admitted Fellows of the College and have received their diplomas:—J. E. Adams, L.R.C.P. Lond., St. Thomas's; K. Black, L.R.C.P. Lond., L.D.S. Eng., Guy's; A. R. Brailey, M.A., M.B., M.C. Camb., Guy's; J. H. Burgess, M.B. Lond., Lieut. I.M.S., St. Mary's; E. R. Carling, M.B., B.S. Lond., Westminster Hospital; N. Carpmal, L.R.C.P. Lond., St. Thomas's; J. Clay, M.B., B.S. Durh.; W. F. H. Coke, L.R.C.P. Lond., St. George's; H. Davies-Colley, B.C. Camb., Guy's; R. C. Elmslie, M.B., B.S. Lond., St. Bartholomew's; T. J. Faulder, L.R.C.P. Lond., Camb., and St. Bartholomew's; R. J. Ferguson, M.D., M.Ch. R.U.I., King's College and Middlesex Hospital; C. B. Goulden, M.B., B.C. Camb., Middlesex Hospital; W. L. Harnett, M.B., B.C. Camb., St. Thomas's; F. J. Hasslacher, M.B. Lond., King's College Hospital; S. Hastings, M.B., B.S. Lond., Middlesex Hospital; J. A. Hayward, M.D. Lond., St. Bartholomew's; H. A. Lyth, M.B., B.S. Lond., University College Hospital; D. J. McGavin, M.D. Lond., Mason College, Birmingham and London Hospital; A. McNab, M.B., Ch.B. Ed., London Hospital; C. E. Marriott, M.C. Camb.; A. T. Moon, L.R.C.P. Lond., London Hospital; F. H. Parker, M.B., B.C. Camb., Guy's; H. D. Pollard, M.B. Lond., London Hospital; W. A. Rees, M.B. Lond., Middlesex Hospital; N. I. Spriggs, M.B., B.S. Lond., Guy's; H. B. Tawse, M.B., Ch.B., Aberd., London Hospital and King's College, London; H. Upcott, L.R.C.P. Lond., St. Thomas's; N. E. Waterfield, M.B. Lond., St. Bartholomew's; G. E. Waugh, M.D. Lond., Camb., and University College Hospital; and C. F. Walters, L.R.C.P. Lond., University College and Royal Infirmary, Bristol, and King's College, London.

Society of Apothecaries of London, January, 1905.

THE following candidates have passed in:—
Surgery.—T. H. Jones (Sections I. and II.), R. C. Richards (Section I.), A. M. Walker (Sections I. and II.), J. M. Wall (Sections I. and II.).
Medicine.—J. B. Bradley (Section I.), P. F. Howden, T. H. Jones (Sections I. and II.), T. R. Roberts (Section II.), J. H. K. Sykes (Sections I. and II.), M. C. Vivian (Section I.).
Forensic Medicine.—A. B. Gosse, M. E. Jeremy, T. H. Jones, J. H. K. Sykes.
Midwifery.—C. G. Grey, M. E. Jeremy, T. H. Jones, A. M. Walker, P. C. West.
 The Diploma of the Society was granted to the following candidates entitling them to practise Medicine, Surgery, and Midwifery:—P. F. Howden, M. E. Jeremy, T. H. Jones, and A. M. Walker.

Notices to Correspondents, Short Letters, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive Signature or Initial*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

ORIGINAL ARTICLES or **LETTERS** intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in re-forwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

"THE IMMEDIATE REPAIR OF LACERATION OF THE PERINEUM."

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

Sir,—The heading of Dr. Laphroth Smith's paper seems rather anomalous, as he introduces sutures in cases where no "repair" may be required.

"Meddlesome midwifery is bad."

To stitch when there's no tear is sad.

That wretched rhyme,

("A stitch in time")

I don't consider fair.

Such is abused

When it is used

When there exists no tear.

If parts are stretched, and muscles tired,

You'll find no stitching is required.

Yours, &c., A.D.

G. P. (Croydon).—The question often arises. If your patient went to the consultant repeatedly without your knowledge he can hardly be blamed for attending her at her own house when requested. From the facts as laid before us we should think there would be little advantage in standing upon one's dignity in the matter. At the same time there will be no harm in your writing to the consultant fully upon the point.

WANDSWORTH.—The best man to call in is an authority upon the action of poison, as his evidence will naturally carry most weight both with judge and with jury.

SPECIALIST.—Your remedy lies in a court of law, that is, if you can definitely trace the authorship, and prove the utterance of the slander. If you take our advice, however, you will let the matter drop, rather than slide into the possibly bottomless pit of litigation.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, JANUARY 25th.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m. Mr. M. Collier: Clinique. (Surgical.) 5.15 p.m. Mr. E. T. Collins: Glaucoma (with lantern illustrations).

CENTRAL LONDON THROAT AND EAR HOSPITAL (Gray's Inn Road, W.C.).—5 p.m. Demonstration.—Dr. Wylie: Naso-Pharynx.

THURSDAY, JANUARY 26th.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM (11 Chandos Street, Cavendish Square, W.).—8.0 p.m. Card Specimens will be shown by Dr. L. Cole-Baker and Mr. W. H. Jessop. 8.30 p.m. Papers: Dr. F. Ferguson: A Case of Malignant Disease of the Conjunctiva.—Mr. A. Lawson: Treatment of Corneal Ulcers with Quinine.—Mr. O. Worth: Notations of Prisms.—Dr. D. J. Wood: Two Unusual Cases of Detachment of the Retina.]

HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne Street, Edgware Road, W.).—8 p.m. Clinical Evening. Patients in attendance at 8 p.m.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22 Chenies Street, W.C.—4 p.m. Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m. Mr. E. Willett: Anaesthetics.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—4.30 p.m. Mr. H. W. Carson: The Present Position of Gastric Surgery.

MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (7 Fitzroy Square, W.).—5 p.m. Lecture: Dr. J. E. Squire: Adventitious Sounds in the Pulmonary Disease and their Significance. (Post-Graduate Course.)

FRIDAY, JANUARY 27th.

CLINICAL SOCIETY OF LONDON (20 HARVEY SQUARE, W.).—8 p.m. Exhibition of Clinical Cases followed by Discussion. Patients will be in attendance from 8 to 9 p.m.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN (17 BLOOMSBURY SQUARE, W.C.).—8 p.m. Papers:—1. Prof. A. W. Cromley: Pharmaceutical Regulations in Germany.—Mr. P. H. Martden: The Laws Relating to Pharmacy in Russia.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m. Mr. L. Paton: Clinique. (Bye.)

TUESDAY, JANUARY 31st.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—4.30 p.m. Mr. H. W. Carson: Diseases of the Naso-Pharynx.

Vacancies.

Leeds General Infirmary.—Resident Medical Officer. Salary £100 per annum, with board, residence, and washing. Applications to the Secretary to the Faculty.

Monmouthshire Asylum, Abergavenny.—Junior Assistant Medical Officer. Salary £150 per annum, with board, lodging and washing. Applications to the Medical Superintendent.

County Asylum, Eainhill, near Liverpool.—Assistant Medical Officer. Immediately. Salary £150 per annum, with furnished apartments, board, attendance, and washing. Applications to the Medical Superintendent.

Bolton Infirmary and Dispensary.—Junior House Surgeon. Salary £100 per annum, with furnished apartments, board and attendance. Applications to the Hon. Secretary, W. W. Canon, Esq., 20 Maudslay Street, Bolton.

Manchester Hospital for Consumption and Diseases of the Throat, and Chest.—Resident Medical Officer. Salary £100 per annum, with board, apartments, and washing. Applications to C. W. Hunt, Secretary, Hardman Street, Deansgate, Manchester.

Manchester Children's Hospital, Pendlebury.—Lady Superintendent. Salary £100 per annum, with board, rooms, washing, and attendance. Applications to the Secretary.

Liverpool Dispensary.—Assistant Surgeon.—Salary £100 per annum, with board and apartments. Applications to Sam E. Leicester, Secretary, 56 Vauxhall Road, Liverpool.

Chester General Infirmary.—House Surgeon. Salary £100 per annum, with residence and maintenance in the house. Applications to the Chairman of the Board of Management.

Ancoats Hospital, Manchester.—Resident House Surgeon. Salary £100 per annum, with board, residence, &c. Applications to Saml. Baron, Secretary.

Sunderland Infirmary.—House Physician, House Surgeon, Assistant House Surgeon. Salary £100 per annum, with board, residence and washing. Applications to the Secretary.

East London Hospital for Children, and Dispensary for Women, Shadwell, E.—Pathologist and Registrar. Salary £100 per annum. Applications to Thomas Hayes, Secretary.

Egyptian Government—Ministry of Public Instruction.—Professor of Pathology and Bacteriology at the School of Medicine, Cairo. Salary £200 per annum, private practice not allowed. Applications to the Director, Government School of Medicine, Cairo, Egypt.

North of Ireland.—R. C. Doctor for a good practice. D., Dublin Office of this paper. (See Advt.)

Appointments.

HOBSON, H., M.B., M.S. Lond., Certifying Surgeon under the Factory Act for the Alresford District of the county of Hants.
SCOTT, C. E., M.B., C.M. Edin., Certifying Surgeon under the Factory Act for the Abingdon District of the county of Berks.

Births.

BLAKE.—On Jan. 13th, at Bentley, Maidstone Road, Grays, Essex, the wife of Anthony Fewster Blake, M.R.C.S. (late of Nailsworth, Glos.), of a daughter.

Marriages.

BROCKWELL—SMITH.—On Jan. 18th, at Christ Church, Gipsy Hill, John Brocas Chambers Brockwell, M.R.C.S. and L.R.C.P., eldest son of the late Dr. John Brockwell, of Gipsy Hill, S.E., to Annie Amelia, elder daughter of the late William Edwin Smith, of Lewes, Sussex.

McHATTIE—BRADOR.—On Jan. 18th, at Portland, Dorset, A. C. N. McHattie, M.B., of Haxey, Lincolnshire, to Alice, youngest daughter of the Rev. Canon and Mrs. Beason, The Rectory, Portland.

Deaths.

PENNY.—On December 19th, near Mombasa, British East Africa, William John Penny, F.R.C.S., formerly of Clifton, Bristol, and eldest son of William Penny of Crewkerne, Somerset.

WEST.—On Jan. 18th, at 16 Church Square, Taunton, Rowland Hill West, M.A., Cantab., M.R.C.S., L.R.C.P., L.R.C.A., Cert. Fact. Surg., aged 62.

THE VALUE OF SCIENTIFIC METHOD IN THE STUDY OF LARYNGOLOGY. (a)

By CHICHELE NOURSE, F.R.C.S. Edin.

Surgeon to the Central London Nose, Throat, and Ear Hospital.

NEEDLESS to say, for the healthy and vigorous existence of a Society like this the co-operation of every member is needed; moreover, it is a duty incumbent upon all engaged in the study of any branch of medicine to contribute what we can to the common store of knowledge. Our first illustrious President, Sir Morell Mackenzie, spoke of this duty in the able and eloquent Address, pregnant with suggestions for his younger *conferres*, with which he inaugurated the work of the opening session of this Association, the oldest of the kind in the United Kingdom. He, with some of those who heard him, has passed away; but his words remain. "Those," he said, "who are content perseveringly to interrogate Nature in her everyday dress will, I am persuaded, be fully compensated for such courageous humility. . . Work steadfastly, then, whether the subject be recon-dite or apparently trivial. Observe and test everything, and bring your results here to be criticised by your fellow-workers." Those are his words. Since that time much has been accomplished, but there is still work for us to do; now, I think, more than ever, for, with deeper insight, the complexity of the subject is more clearly seen, and new factors, hitherto unsuspected, appear in view.

Our field of work, it is true, is in part overlapped by that of each of our distinguished sister-societies; but, considering the increasing importance of that field, the rapidly-growing band of workers, the more numerous hospital clinics, and the ceaseless activity of research and observation in every direction, there must be ample material in this Metropolis alone to supply even more societies than those already existing. Moreover, it is of advantage, both to the medical profession and to the community at large, for the sake of greater freedom of thought, that there should be more centres than one for the record of observations and for the discussion of interesting questions. It will, I hope, be demonstrated by the work of the present session, as it has been in the

past, that there is among us the same enthusiasm for good work which characterised the Association in the first flush of its youth, when those distinguished workers, now, alas, no more, were still with us. In a few weeks' time the Association will be called upon to join with the Laryngological Society of London and the other laryngological societies of the world in celebrating the hundredth birthday of Señor Manuel Garcia, the inventor of the laryngoscope, to whom we have already paid a tribute in electing him an Honorary Fellow. It was fifty years ago that the desire of studying the action of the larynx during singing led him to devise the instrument. He presented the result of his observations, made upon his own larynx, to the Royal Society in the year 1855, in the form of a paper entitled "Physiological Observations on the Human Voice." Coldly received at first, and regarded merely as a physiological toy, this practical application of the laws of reflected light has revealed a new horizon in the world of medicine, and, in doing so, has helped to relieve the sufferings of countless numbers of our fellow-creatures.

It is an additional gratification to us, who are about to pay homage to this venerable master, as doubtless it is also to him, to know that he has lived to see the value of his invention to medical science. It is almost as difficult for the laryngologist of the present day to realise that there was any possibility of acquiring a knowledge of the diseases of the larynx before the invention of the laryngoscope as it must be for the modern physician to imagine how his work could have been done without the aid of a stethoscope. We are, indeed, much more favoured than the men of former days in so many ways that there is small excuse if our work is not careful and accurate. The value of the habit of accurate observation was once before so delightfully illustrated by Dr. Milligan in the course of a Presidential Address from this chair that it is needless to dwell upon it again. It is a faculty for which the practice of our profession forms an excellent school. Hence, the literature of medicine, including that of our specialty, abounds in full and accurate records of observations. But, besides this, the part played by reason in the advancement of knowledge needs to be recognised. Records of facts alone do not constitute a science; it is necessary to bring to bear upon them the methods of inductive reasoning. For knowledge consists of conclusions drawn by reason from the consideration of facts. Thus, on the one hand, reason is applied to facts in order to build up the principles of medicine; and,

(a) Presidential Address delivered before the British Laryngological, Rhinological and Otological Association, January 13th, 1906.

on the other, the use of both inductive and deductive logic is indispensable in the practice of the healing art. The exercise of reason being intuitive, it is used by all from the very cradle, and upon every circumstance of life. But the uncultivated intuitive sense, without the aid of rules, is not always able to distinguish sound reasoning from false; it is, therefore, very liable to lead to error, even in ordinary matters.

Still less can it be trusted for dealing with serious scientific subjects. In medical science especially, where the data are so few in comparison with the unknown and often unsuspected factors, the issues are too important for it to be safe to form general conclusions without the greatest circumspection. Yet, in practice, it is often necessary to be provided with provisional hypotheses, where better-established theories are wanting. Accordingly, we find ourselves constantly devising working hypotheses, and reasoning from them by deduction. Provided they are based upon recorded facts, and are recognised as provisional, there is nothing to be said against their use. They are, indeed, the merchant-vessels of knowledge. Some, enduring the test of experience, gradually become accepted by the profession. Others disappear and give place to new and better ones; but a few of the wrecks of bygone theories still float about, like derelicts on the ocean, which are dangerous to navigation and very difficult to dispose of.

A mere conjecture—that is, a hypothetical proposition unsupported by actual facts—is never worth much, even when uttered by an authority, and may become dangerous by repetition. Dogma has no place in scientific medicine. Reasoning by analogy, too, is hardly ever very safe, although so commonly employed. When two things are alike in very many characters, it is probable, but not certain, that they are similar in some other respect. But when the analogous characteristics are only few, it is impossible to draw a conclusion with regard to the rest.

For the right use of reason, accuracy in the use of terms is demanded, which should not be ambiguous nor too greatly multiplied. Care should be taken to separate fact and theory; and in recording facts to keep the mind absolutely impartial, for there is a curious tendency to ignore observations which do not fit in with preconceived notions. For this reason, too, the observations of facts should be verified more than once. The application of general principles to individual instances always requires care. The teaching, at one time fashionable, that a conclusion could be reached at a glance is, no doubt, obsolete; but there is still sometimes an inclination to lean too heavily on one fact, instead of basing the judgment upon the sum of all.

It is not altogether surprising that the mediæval universities came to regard logic as the essence of learning instead of, as we know, the means to an end. The process of inductive reason is the only safe path by which to arrive at truth. There is no royal road. It is slow, because the collection of so many observations needs time. It is difficult on account of the care needed for making observations and records; and because of the necessity for the elimination of all bias. But it is the one way in which all great discoveries in science have been made. In the immortal work of Charles Darwin it is hard to say which is the

most admirable, the patience with which he had collected his enormous array of facts, the wonderful manner in which he was able to handle them, or the sublime grandeur of his conclusions. There is, indeed, nothing which gives such a sense of satisfaction to the intellect as a well-reasoned argument. The mind is led on, step by step, from one point to another, until at length it rests content upon some incontestable verity.

The subject of reason in relation to our scientific work would be incomplete without a reference to literary composition, with which it is so closely related. Writing is the chief method of disseminating reasoned thought. Not only is a clear literary style the mark of accurate perception, but the effort at clearness of expression tends to develop precision and accuracy of ideas. "Reading," says Lord Bacon, "maketh a full man; conference a ready man, and writing an exact man."

But the perspicuous writer upon medical subjects reaps other advantages. His meaning being clearly expressed, his writings are pleasant to read and easily understood; and therefore more likely to be read. Even the briefest record of a case gains immensely in value by being clothed in suitable language. Apart from the value of the subject-matter, well-written works tend to live, and they shed an additional lustre on the names of their authors. What grace and charm are to be found in the writings of Sir Morell Mackenzie, of Sir James Paget, and in those old "Lectures on the Principles and Practice of Physic," written in 1843 by Sir Thomas Watson, which may still be read with enjoyment and advantage.

The object of this Association, stated in our Constitution, is "the advancement and diffusion of knowledge in all that relates to diseases of the throat, nose and ear." We are not merely students, but professedly teachers of these subjects. We teach, in the first place, by learning ourselves. Besides this, some of us are actually called upon to impart what we know to students in the course of hospital work. It is our bounden duty, therefore, to test and retest the truth of our beliefs before imparting them to others. Accurate and unbiassed observation must be wedded to sound reason.

THE MILK SUPPLY OF EDINBURGH: WITH SUGGESTIONS FOR ITS MORE STRINGENT CONTROL. (a)

By AITCHESON ROBERTSON, M.D. Edin.

THE importance of a proper dietary during infancy and childhood is immeasurably greater than at any other age-period. Without discussing the pathogenesis of infantile disease, one may yet inquire why so many young children suffer from tuberculosis. The organism cannot enter through a healthy intestinal mucous membrane, and probably the most common cause of loss of resistance is the enfeeblement of the mucosa from the ingestion of milk which is commencing to putrefy. Of the many organisms common in milk, the most abundant are those which cause the lactic acid fermentation; hence "souring" is the first easily recognisable sign of putrefaction. Fresh milk from pasture-fed cows is faintly alkaline, that from stall-fed cattle often acid from the presence of the lactic acid organisms in the

(a) Read before the Edinburgh Medico-Chirurgical Society, January 18th, 1905.

teats or milk pails. In any case the lactic acid fermentation commences in this milk very rapidly indeed. This early acidity of milk is readily estimated, and may be taken as a standard of the freshness or staleness of the fluid. In samples of fresh new milk got from thirty-one shops the acidity varied from .112 per cent. of lactic acid to .3 per cent. When lactic acid is present to the extent of .2 per cent. the milk has a sour taste; at .25 per cent. it is unfit for consumption as a food. In more than half the shops (these were in the poor quarters, and the samples taken during warm weather) the milk had reached such a stage of putrefaction as to preclude its use as an infant's food. Such milk as this would certainly produce diarrhoea, though not necessarily the fatal type of epidemic summer diarrhoea, which is probably due to an organism of the colon group, and results from specially virulent milk pollution, in which the determination of the acidity is no use as an index of the degree to which it has proceeded. The intercommunicability of human and bovine tuberculosis must be regarded as proved. With care, no tubercle organisms should get into the milk, but with the present want of care one cow might easily infect the whole dairy supply. The percentage of samples in which tubercle bacilli have been found is very variable—3.7 in Manchester, 22 in London, 28 in Liverpool, 30.40 in Paris, and once in Cambridge as high as 56.2. It must at least be conceded that tuberculous infection of milk is not infrequent, and it seems that such milk is peculiarly liable to act prejudicially on children debilitated from diarrhoea. The immense advantage of breast-feeding is nowhere more evident than in this connection. The reason why tuberculosis is so common in dairy cows is the unhygienic state of the byres. No other article of food is prepared under such insanitary and filthy conditions as milk, and it is the only article of diet which is partaken of raw. There are still many cowsheds in the centre of the town—115, licensed to contain 3,417 cows. Many of these are hidden behind tenements, in lanes or alleys, the cows are never allowed out so long as they continue to give milk in paying quantity, and as it seems proved that a cow gives more milk when kept in a warm, confined atmosphere than when allowed into the open, there is no difficulty in seeing the inducement afforded to prolong the present state of matters. In one instance, extreme, it is true, a cow had gone on yielding milk for six years. The cubic space, even when sufficient to satisfy the requirements of the Act, is in most cases insufficient, as all sorts of expedients, such as opening connections between lofts and byres, are adopted to include in the space estimated air which is not available for respiration, which is stagnant, and which may even be positively bad, by coming from a reservoir of foul air. By the Act of 1866 a minimum of 800 cubic feet is required for each animal, except in the case of byres existing before that date, in which the amount is fixed at 600. Few of the present cowsheds have been built since the passing of the Act. The legal minimum is fixed far too low; not less than 1,000 cubic feet, and that distributed over a proper floor space, should be allowed. In most sheds at present only twenty-eight square feet is allowed for each animal. Ventilation is almost entirely neglected in these city cowsheds. On the basis of computation generally

used for estimating the air required in human habitations, it is found that each cow ought to get between 9,000 and 10,000 cubic feet of air per hour. Dr. Robertson has frequently tested the inlets and outlets with the anemometer, and found the results highly unsatisfactory. The usual method of ventilating is to have as outlets ridge openings in the roof, and as inlets perforated bricks at a height of nine feet from the floor. Such an arrangement, of course, does not ventilate the byres at all. The cowkeeper, too, has a horror of ventilation, which, he affirms, diminishes the yield of milk and causes the animals to take chills. The extreme prevalence of tuberculosis in dairy-fed cattle is due to these factors: overcrowding, absolutely inadequate ventilation, and want of sunlight and exercise. The disease occurs in from 20 to 40 per cent. of such animals, though comparatively rarely in the form of tuberculous mastitis, which occurs in only from 2 to 4.8 per cent. It is not true that only milk from a tuberculous udder contains the germs; it may contain them if the cow has any form of tuberculous disease. The increase of tuberculosis among cows during the past few decades has corresponded with the growth of the custom of keeping the animals confined in byres so as to increase their milk supply. The facility with which the disease spreads under these circumstances may readily be understood when we remember how careless and imperfect are the means employed of cleansing the byre of manure, urine, and so on, in both of which, and in expectoration on the walls of the stall, tubercle bacilli have often been detected. It should be noted that it is not until the disease has reached an advanced stage that emaciation takes place. Apart from the condition of the animals, the method by which the milk is collected is utterly insanitary. Absence of any attempt to groom the cows, or to remove the hardened faeces which encrust their flanks, absence of any facilities for the milkers cleansing their hands or wearing clean overalls, and, finally, the fact that on the same employé devolves the duty of cleansing the byre as well as milking the kine. These considerations lead one to be surprised, not at the filth the milk contains, but at the fact that it does not contain more. The only treatment to which the milk is subjected is to pass it through a wire gauze sieve, which keeps back the larger particles of solid impurity. Another highly insanitary feature of most city byres is the accumulation of manure only a few yards from the byres. It is not compulsory to remove this oftener than once a fortnight. No doubt the remedy for this state of matters is to have the dairies in the country so that the cows can live healthy lives. It is quite fallacious to imagine that it is an advantage to get the milk from a byre in the city, on the ground that the milk so obtained is freer from organisms on account of the less time which elapses before it reaches the consumer. The growth of organisms can be completely inhibited by refrigeration, but even this elementary means of preserving milk is quite in abeyance in the city byres of Edinburgh. The number of organisms in 1 c.c. of freshly-drawn milk from these byres varies from 50,000 up to millions; in a well-conducted country dairy farm it should not have more than from 5,000 to 30,000, the latter being the maximum standard for certified milk in New York. The only remedy for this state of matters is the

municipal control of the milk supply, through regulations somewhat after the following:—(1) Abolition of cowsheds within city boundaries; (2) dairy farms should all be situated in the country; (3) careful veterinary inspection to secure healthy cows; (4) application of tuberculin test every six months; (5) pasture-feeding as far as possible, when artificial foodstuffs need to be carefully selected; (6) cows to be kept in the open air except during the most inclement weather; (7) 1,000 to 1,200 cubic feet of air for each animal in the sheds; (8) thorough ventilation, allowing 8,000 to 10,000 cubic feet of air an hour per head; (9) attention to lighting and drainage of shed; (10) removal of manure frequently in the day to a considerable distance from the byre; (11) careful daily grooming and washing of the cows; (12) waterproof covering with hole for udder put on cow before milking; (13) abundant supply of water and proper washing facilities at cowshed; (14) cleansing of hands, udder and teats before milking; (15) milkers to wear overalls, and not to have to do with cleansing the byres; (16) "fore-milk" to be rejected; (17) milk to be received into a covered pan through a funnel opening; (18) milk from each cow to be strained and refrigerated; (19) milk-cans, &c., to be sterilised by boiling; (20) vessels to have locked lids—small cans should be used for each customer, or the milk measured out by a stopcock so as to avoid dippers, pouring milk from one vessel to another, &c.; (21) frequent medical inspection of workers, veterinary inspection of the cows, and bacteriological examination of the milk. These are not counsels of perfection, but obtain in all well-managed dairies. Unfortunately the number of these is too small, and the only way in which there seems any prospect of their coming into general use is by the controlling action of municipal and other local authorities. Until a pure milk supply is obtained the duty of practitioners is: (1) To insist on maternal nursing, wherever possible—donations of money to nursing mothers have been found useful in France, and the "Gouttes de Lait" have also done good in this way, but it is doubtful whether these would suit English custom; (2) the most ready means of dealing with milk so as to render it innocuous is by Pasteurisation or sterilisation, and as Pasteurisation at home is out of the question among the very poor, the establishment of milk depôts for its sale is required.

Within ten years the death-rate of children under three years in New York has fallen by one-half on account of the more extended use of pure milk. It is doubtful whether the absolute prohibition of the use of preservatives, such as boric acid or formalin, is beneficial to the community. Just because they are forbidden they are likely to be added without due care. Formalin in the proportion of 1 to 30,000 is an effectual preservative and is absolutely harmless. In conclusion, the speaker urged the formation of a medical committee to consider the question of the Edinburgh milk supply.

NASAL OBSTRUCTION AND MOUTH-BREATHING.

By J. SIM WALLACE, D.Sc., M.D., L.D.S.

WE who are concerned with the health of the community must look with satisfaction on the progress

which has been made in hygiene and sanitation, for these sciences guard the avenues leading to physical well-being. So, too, we must look with satisfaction on the progress of medicine, and the decrease and eradication of many diseases. So, again, we cannot but be gratified by the general advance of science, which in its application has led to an enormous increase in the production of the necessaries of life, and has even allowed what once were considered luxuries to come within the easy reach of all thrifty members of the community. Lastly, we must feel much satisfaction in the diffusion of knowledge relating to the laws of health to an extent which could hardly have been dreamt of by the medical practitioner of half a century ago. On the other hand, it must cause us disappointment and chagrin when we think of the alarming increase of certain diseases which we are as yet unable to control or prevent. It is one of these troubles which is rapidly becoming more prevalent that we have met to-day to discuss. Nasal obstruction is now quite a common disease, although but a few generations ago it was practically unknown. This can be easily proved, because nasal obstruction and mouth-breathing give rise to a characteristic deformity of the jaws, and to an easily recognisable irregularity of the teeth. The mouth-breather's jaw is absent in all but recent collections of skulls. Even in the Hythe collection, which is probably only a few hundred years old, there is, I understand, not a single example to betray the existence of mouth-breathing at that time.

When we recognise these facts, we naturally ask, What change has taken place which will account for the increased prevalence of nasal obstruction and mouth-breathing? One would naturally suppose that in all probability the artificial warming and imperfect ventilation of houses might be the chief change and initial cause. The sudden changes in temperature to which the nasal mucous membrane is subjected on passing from a heated room to the cold outer air can hardly be otherwise than prejudicial, nor can a stuffy and germ-laden atmosphere be considered conducive to the health of the nasal passages.

Dr. Scanes Spicer holds this view and says: "In this way the nasal mucous membrane gets into a state of inferior vitality and irritable weakness, and erects, inflames and hypertrophies. . . The secretions of the disordered mucous membrane become abnormal and irritate the lymphoid channels and follicles in the naso-pharynx, and adenoid vegetations are the result." That these conditions tend to give rise to morbid conditions of the nose and naso-pharynx is, I believe, generally acknowledged, but that they do not supply a complete explanation of the prevalence of nasal obstruction and mouth-breathing is equally generally recognised.

Another condition, possibly of greater importance, is an interference with the perspiratory function of the nose. The nose is not only a respiratory organ, for it has a perspiratory function also. If we consider what happens when we breathe, we observe that a large amount of air which is drawn into the air passages never reaches the air cells of the lungs at all, but is broken up, forming eddies over the various moist projections and recesses of the nasal cavities. The air which ultimately does reach the lungs gets moistened, of course, but so does that greater amount which is exhaled without ever reaching the lungs at all. When we are at rest in bed and well covered, perhaps too well covered, it is obvious that the general surface of the body is not so well adapted for the perspiratory function as when we are up and moving about, with the air circulating more or less freely around us. In fact, when we are lying at rest the only parts of the body over which a current of air is freely passing are the walls of the nasal cavities and the respiratory passages. It is thus perfectly natural that if we get warm in bed the nasal mucous membrane will get congested, just as the surface of the body gets congested when we become over-heated. If the nasal passages were not unduly narrow, only good would result, for the evaporation caused by the current of air through the nose would help to keep the body temperature normal and prevent

undue perspiration elsewhere. I need not refer to the harmful effects of an undue rise of bodily temperature, or to an undue amount of perspiration at night. What it is of special importance to note is, that the nose is a perspiratory organ, and if the function of perspiration is interfered with, various deleterious results are certain to be brought about. Many known facts seem to corroborate this hypothesis; for example, the fact that nasal obstruction is commonest in damp localities—i.e., localities in which the perspiratory function is carried on under more disadvantageous conditions than when the atmosphere is dry. So, too, the fact that children who are "coddled"—i.e., who are kept too warm, often in a close atmosphere, and in general placed in conditions which tax unduly the perspiratory function, are highly susceptible to colds and nasal obstruction. Then, again, we recognise that in the treatment of these troubles a moderate covering of flannel which will keep the child warm without inducing undue perspiration is beneficial.

Another concomitant of civilisation which plays an important part in inducing nasal obstruction is the unsuitable nature of the food upon which children now subsist. Any great change in the habits or in the environment to which man has, through countless generations, become adapted is almost certain to bring about some harmful results, and that an extraordinary change has come over the food and feeding of children is undeniable. Thus, for example, before cows were kept it is obvious that milk was unknown to children after they were weaned, say between the age of one year and two years, nor were the proprietary foods which imitate milk available for children. Nor was bread, nor porridge, nor milk pudding available, so that the staple articles of the modern child's diet were utterly unknown to the children of primitive man and all his progenitors.

Those who know of nothing but the orthodox milk diet for young children find it almost impossible to imagine how the children of primitive man could possibly have been reared on the natural foods at the disposal of the untutored or un-Chavassed mother.

In order to indicate the magnitude of the change in feeding to which children are subjected, I shall first briefly indicate the kind of diet which the children of our ancestors were able to thrive upon. After the mother's milk began to fail in quantity and quality, and the child had erupted two sharp little incisor teeth, the child had, I believe, to supplement the decreasing milk supply by using its teeth to pierce the succulent and more or less nutritious roots, shoots and fruits which had been procured for it to gnaw and suck. This, together with some little animal food, probably gnawed and sucked from a bone, had to serve in increasing quantity for the decreasing supply of milk until about the thirteenth month, when the first molar teeth appeared and allowed some food also to be actually ground or masticated. After this age was past, the sucking process became gradually abandoned, while mastication became more thorough, until the primitive child became able to eat all and sundry with his parents. Here, be it observed, the carbohydrates, consumed after laborious gnawing and sucking, were unlikely to give rise to indigestion. They were diluted and much too thoroughly insalivated to escape without conversion or preparation for the stomach. Nor were the salivary glands denied their natural stimulus for full and healthy development. If we consider the natural period of lactation, the time of eruption of the gnawing incisor teeth and of the masticating teeth, together with the time of appearance of ptyalin and the natural stimulus for its secretion, we see that the prehistoric child was well adapted for its primitive surroundings, instinctively, anatomically and physiologically. Compare this with the recognised ordinary methods of feeding at the present day and we find that the foods are in but few ways suited for the anatomical, physiological, or instinctive peculiarities of the child. Instead of being gradually weaned and given food which will demand gnawing, sucking and insalivation, it is cheated into gulping down concen-

trated carbohydrate food such as bread soaked in milk, porridge and milk, milk puddings, and potatoes and gravy. It seldom gets the chance of learning to separate the liquid part which is fit for swallowing and leaving or rejecting the innutritious fibre which so often accompanies natural foods. Nor does it get the chance of learning to masticate its food in such a way that the fluid and finely comminuted part is swallowed first, while the less finely ground part which requires further mastication is thrown back on to the teeth again and again until it, too, is finely ground and thoroughly insalivated. In a similar way, the physical homogeneity of the soft milk-soaked diet prevents the stomach from acquiring the habit of allowing the digested part of the food to pass on through the pylorus, while it forces back the insufficiently digested part into the body of the stomach to be more thoroughly digested. But to cut a long story short, the modern child frequently, perhaps usually, falls into a state of chronic indigestion, and three of the consequences which usually follow must be mentioned, as they tend to bring on nasal obstruction. The first consequence of chronic indigestion to which I would refer is a correlated disturbance in the neighbourhood of the naso-pharynx. We know of the flabby state of the tongue and the red and swollen papillæ and sides towards its root. We are aware that even in adults, who are not so subject to inflammatory swellings as children, that "enlargement of the tonsils is not infrequently present in cases of gastric insufficiency," and this is especially so "when occurring in children near puberty" (Sidney Martin, "Diseases of the Stomach"). Finally, that the pharynx is red and congested in many cases of gastric disturbance is recognised by those who have specially directed their attention to this subject. Is it then, a great difficulty to suppose that the pharyngeal tonsil undergoes a similar enlargement to the faucial tonsil? Is it not the case that hypertrophy of the faucial tonsils is presumptive evidence of the enlargement of the pharyngeal tonsil? I need not mention the effect which this enlargement of the pharyngeal tonsil has in predisposing to mouth-breathing, and possibly also to colds, scarlet fever and measles, which in themselves are by no means without suspicion in causing adenoid vegetations.

Chronic dyspepsia with concomitant malnutrition may predispose to nasal obstruction in another way. It would appear to derange the perspiratory function and bring on attacks of perspiration from trivial causes. It is perhaps partly on account of this that the idea of an association between rheumatism and adenoids has arisen, for the disturbance of perspiration, together with cold and damp, is, as we have seen, likely to predispose to adenoids as it does to rheumatism.

Lastly, indigestion may predispose to nasal obstruction and mouth-breathing by the emaciation and

Diagrammatic representation of a section of the mouth and nose to illustrate the palate and position of the teeth when: (1) the tongue has been normal; and (2) when the tongue has been small or emaciated during the development of the palate.

general lack of strength to which it gives rise. How his comes about must here engage our attention. We know that the growth and development of the maxillæ are intimately associated with the growth and

development of the tongue. The general truth of this contention has now been so fully corroborated by the elaborate investigation and careful measurements of Dr. Grevers, of Amsterdam, that I do not feel called upon to recapitulate the evidence which originally led me to recognise this truth. All I need here say is, that a normal or unemaciated tongue stimulates the growth in breadth of the maxillæ and brings about a broad palate.

But just as the palate is made broad by this stimulus, so, too, is the base of the nose similarly broadened, and consequently, the part which is, *par excellence*, the respiratory part is correspondingly broadened. It is known to dentists, at least, that any mechanical force, when acting in the mouth more or less continuously, will expand the dental arches, and if the tongue grows as it ought, it must necessarily press the dental arches outwards also. The suture between the maxillæ allows of the deposition of bone and consequent separation of the bodies of the maxillary bones provided that there is something to stimulate such growth. What could be more natural than that the developing tongue should be the normal stimulus? On the other hand, it is only natural that if the tongue is emaciated, so, too, will the palate lack breadth.

The growth in breadth of the palate is also stimulated by efficient mastication. For with efficient mastication there comes a corresponding wearing of the cusps, especially of the temporary teeth, and a consequent loss in depth of the mouth which is compensated for by a corresponding increase in breadth. If the tongue is compressed from above downwards, the lateral expansion is correspondingly increased. Again, efficient mastication stimulates the growth in breadth of the palate by the fact that it supplies an intermittent strain on the sutures, especially through the more or less transverse action of the external pterygoid muscles. We thus see that emaciation of the tongue, inefficient mastication, and the lack of wear of the teeth brought about by the soft food given to children all tend to produce a narrow palate, narrow jaws, and corresponding lack of breadth of the nasal passages. From similar causes the naso-pharynx not only lacks breadth, but also depth from before back, for an inefficiently developed tongue does not cause that normal forward translation of the maxillæ which a fully developed tongue does; and the lack of the intermittent pressure and strain normally produced, especially by the action of the external pterygoids during efficient mastication, gives rise to a corresponding lessening of the natural stimulation to the deposition of bone between the various sutures which run transversely between the basi-occipital and the maxillæ. Now, in narrow nasal passages and a constricted naso-pharynx we have a strong predisposition to nasal obstruction, and when mouth-breathing is once commenced the chances of spontaneous recovery are almost *nil*, for nasal obstruction itself arrests the further development of the nasal cavities, as has been experimentally proved by von Ziem. Furthermore, nasal obstruction induces mouth-breathing, and this removes the normal pressure of the tongue from the maxillary alveolus on either side so that still further is the natural stimulus for the natural broadening of the palate, and consequently the nasal breathway, removed.

I might here allude to Dr. Harry Campbell's ideas with regard to the beneficent action of efficient mastication in stimulating the flow of lymph and blood, and thus establishing a healthier state of the neighbouring tissues; but I presume you are all well acquainted with his views on these and correlated subjects, (a) and will only say that if his contentions are correct they would help to enforce one of my main arguments—*viz*, that soft foods are responsible for a large amount of indigestion, and indirectly for adenoids among children.

Another cause of imperfect broadening of the nasal passages is the upright posture associated with pro-

longed ill-health and malnutrition. When the health is continuously below par the vigorous tonicity of the muscles is lessened, and instead of the thorax being held up in the manner which is characteristic of robust health, it falls somewhat, and an attitude such as that caused by exhaustion becomes almost chronic. But the fall of the thorax and viscera naturally drags hyoid, tongue and jaw downwards from the palate, thus removing the natural stimulus for broadening it, while at the same time the mouth is actually pulled open.

It frequently happens that the nose is specially congested at night, while but little blocking is observable by day. The congestion by night causes mouth-breathing by obstruction, while the conditions just referred to predispose to mouth-breathing by day. If the child were in vigorous health, the mouth-breathing by day would not take place, and the pathological condition in the naso-pharynx would have a much better chance of recovery. Thus, then, delicate health from indigestion or any other cause not necessitating the horizontal position tends mechanically and otherwise to induce mouth-breathing and concomitant abnormal conditions.

Another condition to which we must just allude is an imperfect development of the lower jaw, where the ramus joins the body. When mastication is vigorously performed the mandible develops fully in the neighbourhood of the angle, and thus a square and broad jaw is brought about; whereas, when mastication is insufficiently carried on the angle remains more obtuse. This obtuseness of the angle of the mandible, however, has an effect on the arrangement of the teeth, for it tends to make the molars meet or occlude before the rest of the teeth. In other words, the mouth is prevented from closing. It is necessarily held open. Other effects follow. The upper molar teeth are forced forward and may either become very irregular, or the incisors may be forced to protrude, and the typical mouth-breathing jaw be foreshadowed. The teeth towards the front of the mouth rise as it were in their sockets till they meet, but it frequently happens that the alveolus is so much deepened that the lips do not close without a special effort, and at least an approximation to the adenoid type of face is closely simulated. From a consideration of these facts it will be seen that the imperfect broadening of the palate associated with mouth-breathing is, or may be, brought about independently of nasal obstruction, and may ante-date it. The stenosis may give rise to obstruction with but little hypertrophy of the lymphoid or other tissue which is so liable to hypertrophy, (a)

In conclusion, it should be noted that if the general truth of my contentions be admitted, then two important corollaries naturally follow. The first is, that "the cure of mouth-breathing should be carried out by the rhinologist *pari passu* with the treatment of the teeth and palate at the hands of the dental surgeon." I give this corollary in the words of a distinguished rhinologist, for his words cannot be supposed to be biased in the way in which mine might be. In the treatment of the irregularities of the teeth we dental surgeons recognise the important help to be derived from the laryngologist in the restoration of the functions of the nose, but I doubt if all rhinologists recognise that some benefit might accrue from the expansion of the palate by the dental surgeon, and by the restoration of the means of efficient mastication.

The second and more important corollary is that we should enter a most vigorous protest against the iniquitous and ubiquitous system of feeding children almost entirely on soft milk-soaked foods. Not because milk is occasionally the bearer of tubercle, scarlet fever, diphtheria, &c., nor because it leads to constipation, fermentation and summer diarrhoea, but because this pap system is the insidious cause of

(a) "Influence of Mastication on the Jaws." "Trans. Odontological Soc.," 1902, p. 102 and 120; also "Observations on Mastication." *Lancet*, July 11th, 18th, 25th, and August 8th, 1903.

(a) A full account of many of the structural alterations caused by mouth-breathing will be found in the author's work on "The Irregularities of the Teeth, with Special Reference to a Theory of Causation and the Principles of Prevention and Treatment."

lifelong suffering from the numerous derangements of the alimentary canal which it brings on. It begins by producing the wholesale ruin of the teeth, together with many consequent troubles. It leads to adenoids and all the unfortunate sequelæ with which you are so familiar. Finally, it almost necessarily begets gastric insufficiency, mal-assimilation, and malnutrition, together with the general wreck of physical well-being which these derangements ultimately produce.

Clinical Records.

CENTRAL LONDON THROAT HOSPITAL.

Case of Lympho-Sarcoma of the Frontal Sinuses.

By DR. P. H. ABERCROMBIE.

With Microscopic Report by DR. WYATT WINGRAVE.

E. D., æt. 75, a widow, attended my clinique at the Central London Throat, Nose, and Ear Hospital, on October 22nd last, complaining of a swelling over the root of the nose, which she first noticed about a month previously. No symptoms of any kind were present, and examination of the nasal fossæ revealed nothing abnormal.

The patient knew of no cause for the swelling, although, after questioning, she remembered having had a blow on the nose "many years ago."

The swelling, which was roundish in form and about half an inch in diameter, was situated in the middle line at the root of the nose. The skin over it was normal in appearance and was not adherent to the growth, which latter, however, was fixed to the bone underneath it. Transillumination showed the swelling to be distinctly translucent, and when it was palpated, the sensation experienced was one of fluid under pressure. Both frontal sinuses were clear. Under the impression that it was a cyst of some kind, I punctured it with a trocar and cannula, but nothing escaped.

I then advised the patient to come into the hospital for operation, but this she postponed until November 18th, nearly a month later, when I operated.

The swelling in the meantime had increased in size to almost double its former dimensions, had become lobulated on its left side, and was no longer translucent. Still, there were no symptoms to speak of. The unsightliness of the swelling was what she complained of.

Under chloroform, an incision was made in the middle line over the growth, and the latter proved to be solid, though soft in consistence, of a grey colour, and attached to the bone. On removing the mass, a perforation was found in the bone communicating with the frontal sinuses, both of which cavities (the right being much the larger) were full of a similar-looking growth, together with polypoid degeneration of the mucous membrane.

There was a slight mesial ridge on the floor and posterior wall of this bony cavity, representing the position of the septum. This large frontal sinus cavity was full of the growth, but was not distended by it, and its bony walls appeared to be normal except anteriorly, where the perforation above mentioned existed. There was no pus present. The whole space was very carefully and thoroughly curetted; every trace of growth, apparently, being removed.

The cavity was packed with double cyanide ribbon gauze and dressings applied. The patient since the operation has done remarkably well, and the wound is now almost healed.

Dr. Wyatt Wingrave has very kindly made a thorough examination of the growth removed, and he regards it to be of the nature of lympho-sarcoma. He himself will read his report in full.

Dr. Wingrave tells me that the structure of this growth closely resembles that removed by me from the frontal sinus of a patient early in 1902; but in this case there was pus in the sinus as well as growth. This patient was shown by me at the May meeting of this Association in 1902, and the chief point of interest in the case was that the attacks of severe pain and tenderness from which he suffered repeatedly were

felt by him over the healthy sinus, and not at all over the region of the diseased one!

Dr. Wyatt Wingrave's Report of Microscopical Examination.—The tissue consisted of round-cells embedded in a homogeneous matrix, containing a delicate stroma of fine white or gelatine fibres. The cells were similar to mononucleated lymphocytes, but somewhat larger and possessing more protoplasm. The nuclei were round and in places exhibited active mitosis. Vascular channels composed of a single layer of epithelioid plates were present but scanty. Reference to the Pathological Register of the Central London Throat and Ear Hospital affords evidence of similar cases in which the histological details strikingly resembled the present case. One of these cases was also under Dr. Abercrombie. The specimens were all prepared by the writer. The tissue belongs to the mesoblastic type and histologically conforms to the lympho-sarcomatous group. No bacteria were found.

ROTUNDA HOSPITAL, DUBLIN.

A Case of Chronic Epithelioma following on Hydatiform Mole—Hysterectomy.

By E. HASTINGS TWEEDY, Master.

Recorded by GIBBON FITZGIBBON,
Senior Assistant, Rotunda Hospital.

THIS case of chronic epithelioma is of particular interest, as the history is very complete, the patient being under observation from the commencement of the disease.

M. W., æt. 29, multipara, admitted to the hospital on July 14th, 1904. She believed herself ten weeks pregnant, and was suffering from a sanious discharge of four weeks' duration. The bleeding had become severe two days before admission to hospital.

On examination, the os, though slightly dilated, did not admit a finger. A diagnosis was nevertheless made of myxoma chorii from a cyst which came away, and the uterus immediately emptied with a flushing curette.

The patient left hospital well on the eighth day. On October 15th she again returned, giving the following history. Hæmorrhage had commenced a few days after leaving hospital, and had continued slight and irregular. On examination, the uterus was found enlarged, soft, retroflexed, being easily replaced. The os was patulous. On the 17th the uterus was curetted, and a small piece of myxoma chorii removed, together with a large quantity of old blood-clot. As the uterus was inclined to bleed, it was packed with gauze, which was removed the following day.

The patient remained well until the 31st, when bleeding again started, and continued slight for several days. The uterus was again curetted, more with the object of exploring the cavity. A single cyst came away, and also some soft, cheesy material was very easily removed from the fundus; whilst removing this it was noticed that the curette passed evenly over the sides of the uterus and the regions of the cornua, but that at the top of the fundus there was a small area where the curette could pass half an inch further as though it had passed through the uterine wall for the greater part of its thickness. The specimen obtained from the first curettage only showed myxoma chorii in frozen section, but when fully prepared with celloidine it showed a marked degree of malignancy. This, and the fact that there was evidence as above of some growth penetrating the uterine wall, it was decided to do hysterectomy immediately.

On November 8th, vaginal hysterectomy was performed by the Master of the Rotunda, and the subsequent examination of the uterus proved the existence of chorion epithelioma. The macroscopic examination of the uterus demonstrated the cavity to be healthy, with the exception of the fundus, where a small excavation about three-eighths of an inch wide and half an inch deep was found. This had almost perforated the uterine wall, there being nothing but thickened peritoneum remaining. The tubes and broad

ligaments were free from infection. The convalescence was uninterrupted, and the patient left hospital in excellent health four weeks after operation.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, JANUARY 29th, 1905.

TREATMENT OF CANCER.

PROFESSOR JABOULAY, of Lyons, has recommended injections of quinine for the treatment of cancer of the breast, stomach, uterus, &c., by which the general condition of the patient is improved and life prolonged.

Dr. Chabannes, of Vals-les-Bains has published a case which confirms, to a certain extent, the utility of the treatment.

A patient who underwent an operation for cancer of the breast in 1899 had a relapse on the cicatrix at the end of the same year. During the four years of the treatment there was injected 15 grains of bi-hydrochlorate of quinine in twenty drops of water, in a series of 20 injections, given as far as possible daily.

At the end of five or six injections, the tumour, which had attained the volume of a small orange, and was adherent to the subjacent osseous structure, very considerably receded, and became mobile and indolent. The ganglions in the axilla also diminished in volume, and the oedema of the hand, with the pains due to compression, disappeared. This effect always followed the first few injections, and the others were continued to maintain the improvement.

In the interval of the injections the condition of the patient remained satisfactory, but at the end of two or three months all the symptoms returned; the tumour increased in volume, the skin became bluish and, above all, the pains were very severe in the arm; at the same time, the oedema of the hand proved the progress of the nervo-vascular compression of the ganglions in the axilla.

The injections were recommenced, and so on for four years, during which time the patient had received 255 injections. At the end of this time she got discouraged and desired to go to Lyons to undergo a course of treatment by radio-therapy.

But this produced no change in her condition, and she finally succumbed.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, JANUARY 28th, 1905.

At the Society for Psychiatry and Nervous Diseases, Hr. Rosenberg showed three children, two brothers and a sister, suffering from

FRIEDREICH'S DISEASE.

The disturbance of vision in the elder boy was preceded by a febrile disease. There were cerebellar ataxy, nystagmus, and dysarthritic speech, unilateral cryptorchismus and subluxation of the lower jaw. The disease was hereditary. Sensibility, mobility, and reflexes were normal. Westphal's sign was absent, and there was no deformity of the feet. In three elder children of the family the nystagmus was present in a rudimentary form. The speaker could not say whether the spinal column or the cerebellum was affected.

Hr. Skoczynski gave an account of his

INVESTIGATION ON THE SPINAL FLUID.

He had been able to perform lumbar puncture in half of his cases without an anæsthetic. In the case of an epileptic he was able to observe the pressure apparatus during an attack. At the commencement of the attack the pressure rose about 30 to 50 cm. During the tonic stage the high pressure was maintained; during the clonic period the pressure underwent violent oscillation and fell away afterwards to the normal. It could almost be predicted when an attack would come on, *viz.*, when for some time the pressure remained below the normal. The cerebro-spinal fluid contained but little albumen, 0.2 to 1 per cent., in the form of

globulins. In paralysis, on the other hand, a considerable quantity of serum-albumen was present. The albumen was greatly increased in amount in cases of organic disease of the central nervous system. Of thirty-five cases, thirty, with undoubted paralysis, contained cell material; in one case of paralysis with an unusual clinical course, the negative result was obtained. There were no cells in one case of syphilis affecting the brain; in hydrocephalus and epilepsy only occasionally; none in alcoholic dementia and encephalitis. The fluid was centrifugated in every case. Cells were numerous in paralysis with acute symptoms. This permitted a certain diagnosis to be made in doubtful cases as was shown in these illustrative cases. Choline was a decomposition product of lecithin. Out of thirty-one cases of paralytic dementia it was present in twenty-eight. It was present in three cases of cerebro-spinal syphilis; not present in hydrocephalus and alcoholic dementia, and abundant in multiple sclerosis. It was specially abundant where there was destruction of nervous tissue. He did not believe that choline excited convulsions.

Hr. Oppenheim did not believe that lumbar puncture was an indifferent procedure.

Hr. Peritz remarked that Fuchs and Rosenfeld had counted the cells of cerebro-spinal fluid as blood corpuscles were counted; this had its advantages. Whether the substance found was choline was not certain, as platinum chloride entered into the same crystalline combination with ammonia and potassium also. Even if it was shown to be choline it was not to be always looked upon as the excitator of epilepsy, for it might happen that lecithin became converted into choline in consequence of the attack, just as in epilepsy. It might be looked upon as the product of excessive muscular action.

Hr. Remak also expressed his doubts as to lumbar puncture. He would examine the spinal fluid of corpses as to choline.

Hr. Ziehen had no fears of a careful lumbar puncture, but never more than from 5 to 10 grms. should be taken at a time.

Hr. Oppenheim remarked that when larger quantities of fluid were withdrawn in cases of arterio-sclerosis, the oscillation in the pressure might cause rupture of a vessel. He was in favour of lumbar puncture only in extreme cases when diagnosis was impossible without it.

Hr. Brodmann reminded the meeting that at the last annual meeting of the Society for Psychiatry, attention was drawn to a series of serious complications brought on by lumbar puncture.

Hr. Fraenkel advised the use of only the finest needles, to avoid after-trickling when the needle was withdrawn.

Hr. Mendel would always obtain the permission of the patient or of his friends previous to performing puncture.

Hr. Skoczynski, in reply, said he had never seen any serious complication in connection with lumbar puncture. Headache or vomiting followed at times. The symptoms that followed were not all due to the operation. He did not believe that his crystallised masses depended on ammonia. Cerebro-spinal fluid from dead bodies could not be made use of as choline also arose from decomposition.

Transactions of Societies.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

MEETING HELD THURSDAY, JANUARY 26TH, 1905.

JOHN TWEEDY, P.R.C.S., President, in the Chair.

DR. FREELAND FERGUS contributed a case of Malignant Disease of the Conjunctiva, through Dr. F. R. HILL, of Carlisle. The patient, a girl, æt. 9, was sent by Dr. Hill in November, 1903. On the lower part of the bulbar conjunctiva were some sprouting vegetations with an appearance not unlike that seen in spring catarrh. The limbus and palpebral conjunc-

tiva were unaffected. It had first been noticed six months previously. The vision was 6/9, and a portion was removed for examination. The pathological report was indefinite. Shortly after the rest was removed and the patient was sent back to Carlisle under Dr. Hill's care. The pathological reports of Professor Muir and Dr. Devereux Marshall showed the growth to be of an unusual character but probably a sarcoma, but its appearance left no doubt as to its being malignant. On March 21st, owing to its rapid extension the whole contents of the orbit were removed, and the patient was sent back on April 14th. On May 23, she was again seen, but the recurrence was so extensive that no operation was possible. The neighbouring glands were also involved, and even at this time there were cerebral symptoms. The child died in October with the tumour of enormous size. The autopsy showed extensive involvement of the brain. The growth was apparently a leuco-sarcoma.

Mr. PARSONS, who had examined the growth, said it appeared to him to be one of those rare cases when some nævoid tissue takes on malignant growth and he looked upon it as being probably an epithelial growth rather than a connective tissue one.

Mr. ARNOLD LAWSON read a paper on "The Treatment of Corneal Ulcers by Quinine." The object of the paper was to bring more prominently before the profession the great value of quinine in ulcerative affections of the cornea. Up to the present time its use in ophthalmology has been restricted to a very limited class of conjunctival and corneal affections; but the author's observations, extending over four years, showed that it is a powerful curative agent in a large variety of corneal ulcers which are not amenable to ordinary routine treatment. The sulphate of quinine dissolved carefully in just sufficient sulphuric acid to hold the salt in solution is preferable to either the hydrochloride or the acid sulphate, both of which are soluble in water; and it is recommended to be used in a 1 per cent. solution. The eye should be soaked in the solution for five minutes four or five times a day, and thoroughly irrigated daily by an undine filled with the solution is advised. It causes very little discomfort, and patients use it readily, but stronger solutions give rise to pain and have no advantage. If no manifest benefit is effected within a week it may be discontinued. The rapidity of healing under this treatment is at times remarkable, and the author has seen many formidable-looking ulcers heal by this treatment alone within a week.

Mr. CLAUD WORTH read a paper on the "Notation of Prisms." He said that when one orders a spherical or cylindrical lens one does not concern oneself with the refractive index of the glass of which it is made; one specifies that it shall have a certain definite effect upon a pencil of light, and bring it to a focus at a certain specified distance. But prisms are numbered by most opticians according to the geometrical angle, so that if one wants a prism which shall deflect a pencil of light say 4° , one has to order a prism of 8° geometrical angle. The optician then supplies a prism whose actual deflecting power is somewhere between 3° and 5° , according to the kind of glass of which it is made. It is much more convenient and accurate to number a prism according to the number of degrees which it deflects a pencil of light. Although this matter had been discussed before, yet he brought it forward in the hope that the Society would make some definite pronouncement which would be accepted by spectacle-makers in this country and much inconvenience would thus be avoided.

Dr. D. J. WOOD (Cape Town) first of all referred to a case of Detachment of the Retina, which he had recorded in Vol. 12 of the "Transactions." He then described another case which he had recently seen, which bore a strong likeness to the previous one. The patient was a bucolic Dutchman, *æt.* 35, whose right eye had been lost five years before from a perforating ulcer, and the eye had been removed. Since that time the sight of the left had been failing, but had rapidly deteriorated during the last five weeks. His vision was

P.L., and he could just see large objects moving below. The pupil was active and the tension was normal. The ophthalmoscope showed two rounded detachments meeting widening out above. The vitreous was clear and one could just see below the disc, but the striking feature was the swelling and tortuosity of the vessels, which at once recalled the former case to mind. The vessels were more than double their natural size, and were tortuous to a degree. Both arteries were constricted at frequent intervals so that the arteries looked like beads, while the veins had the appearance of strings of sausages. The constricting bands were retinal in origin and looked as if they were stitches holding the vessels down. In both cases it was difficult to follow the vessels, not only on account of the tortuosity but also because the colour of the arteries and veins was so similar. There were no recent hæmorrhages, but some patches that were seen probably represented old ones. The question is whether it is a proliferation of inflammatory material in the retina or a primary disease of the vessels. Probably serous exudation caused detachment of the retina, but it is difficult to account for the lightness of colour of the veins which was seen in both cases.

Mr. LOUIS WERNER showed a sketch of a case of Neuro-Retinitis of a severe type which occurred in one eye of a girl, *æt.* 24, who was anæmic. There was neither headache nor vomiting, the only symptom being a feeling of lassitude, &c., and for a time excessive thirst. There was no albumin present, but the sugar reaction was doubtful. The left eye failed suddenly one morning and the vision was reduced to hand movement. The field of vision was greatly contracted, but the colour perception was good. The upper part of the disc was greatly swollen, with large corkscrew-like vessels spreading out from it, while the lower part was white and atrophic but indistinct. In less than three days a perfect star of white lines appeared at the macula. Under iron the swelling disappeared in three months, and the vision improved to 6/36. The author referred to a case reported by Gowers in which retinal changes resembling those of albuminuric retinitis occurred in a chlorotic patient.

Dr. L. COLB-BAKER showed an ingenious needle-holder for use with either straight or curved needles and a modification of Clark's eye speculum.

Mr. BISHOP HARMAN showed a case in which there was congenital absence of the internal and external rectus muscles.

Mr. SECKER WALKER showed a radiograph of a case of gun-shot wound in which two shots had entered the eye at the same hole and had lodged at the back of the orbit.

ROYAL ACADEMY OF MEDICINE IN IRELAND. SECTION OF SURGERY.

MEETING HELD FRIDAY, JANUARY 13TH, 1905.

Mr. G. JAMESON JOHNSTON in the Chair.

EXHIBITS.

Mr. MAUNSELL exhibited a patient upon whom he had operated for acute cholecystitis, and subsequently for gangrenous appendicitis; also a gall-bladder removed for phlegmonous cholecystitis, and another for hydrops.

Mr. C. ARTHUR BALL exhibited—(a) Prostate removed by perineal prostatectomy; (b) Prostate and calculi removed by conservative perineal prostatectomy.

Mr. MAUNSELL read a paper entitled CHOLECYSTOTOMY FOR ACUTE CHOLECYSTITIS FOLLOWING TYPHOID FEVER.

The cholecystitis manifested itself on the 27th day after the patient's admission to Mercer's Hospital. The muco-pus removed from the gall-bladder contained a pure culture of Eberth's bacillus as proved by numerous tests. Mr. Maunsell briefly described the affections of the gall-bladder which may complicate enteric fever, and strongly advocated operative treatment, quoting cases and statistics in support of his contention.

Mr. JAMESON JOHNSTON related two cases of typhoid

fever in which complications had arisen calling for surgical intervention. In one there was necrosis of the laryngeal cartilages, and in the other there was a chronic abscess of bone, and in both typhoid bacilli were found in the pus.

Sir CHARLES BALL had seen many cases in which disease of bone had occurred many months after typhoid fever. He related a case also in which, during the acute stage of the fever, a large abscess developed in the upper lobe of the lung.

Dr. FINNY considered that the question of interest in Mr. Maunsell's case was whether the acute cholecystitis was a complication of the acute fever or a *sequela*. These complications were to be expected, not in the height of the fever, but just when the patient seemed to be getting better. He did not think typhoid bacilli were the sole cause of the complication in the present case, as they are often found in great numbers in the gall-bladder without any results, locally or otherwise, in the neighbourhood. Mr. Maunsell's patient first came under observation on account of a septic finger, and it was just possible that septic organisms were associated subsequently with the typhoid bacilli.

Mr. MAUNSELL, in reply, stated that in looking up the literature of the subject he had noted instances of complications arising fourteen and a half years after typhoid fever, and in which pure cultures of the typhoid bacillus were obtained. He had thought of the possibility of the crushed finger having had something to do with this case, but on very careful examination no septic organisms could be found.

CONSERVATIVE PERINEAL PROSTATECTOMY.

Mr. C. ARTHUR BALL introduced this subject by referring to the methods of prostatectomy as usually performed by the suprapubic or perineal route, which he considered could not be regarded as ideal surgical procedures, for the prostate had to be removed largely by the sense of touch; hæmorrhage during these operations was not fully under control; and the amount of injury inflicted on the bladder, urethra, and ejaculatory ducts was frequently considerable. He said, the question we had to decide was, Can the prostate, or rather a sufficient part of the prostate, be removed so as to cure the patient without inflicting permanent injury to important anatomical structures? Perineal prostatectomy, as performed by Dr. Young, of the Johns Hopkins Hospital, seemed to him to fulfil these conditions more fully than the methods previously advocated. He then proceeded to explain Young's operation of conservative perineal prostatectomy, illustrating the various steps of the operation by means of lantern slides, showing that the lateral and median portions of the prostate could be removed without injuring the mucous membrane of the bladder or the urethra and ejaculatory ducts, a matter of some importance now that prostatectomy is being done in younger men.

Mr. JAMESON JOHNSTON stated that he had always performed the suprapubic operation, and still thought it the right one. He did not think there were such things as lobes in enlarged prostate; the prostate was simply adenomatous, and there was no definite lobar arrangement. The ingenious idea of Lane's operation was to be admired—*viz.*, the preservation of the ejaculatory ducts.

Mr. EDWARD H. TAYLOR stated that he had had the privilege of being present at Mr. Ball's prostatectomy operations. He had previously no experience of the perineal method, but had performed the suprapubic operation, and was much impressed in its favour. It was not very difficult, but left much to be desired as one had to work largely by the sense of touch. He was impressed by the ease with which the prostate could be exposed by means of a curved incision in front of the anus, the facility with which the capsule could be peeled off the lateral lobes, and the large veins of the vesico-prostatic plexus avoided. Against the operation was the fact that it entailed an extensive dissection and division of the compressor urethra muscle. There was considerable risk, therefore, of

injuring the sphincteric apparatus of the bladder, with subsequent incontinence of urine. There was much less risk of incontinence with the suprapubic operation.

Mr. MAUNSELL thought it was a mistake to say that all cases should be done either by the suprapubic or by the perineal operation. His experience was only with the former, because in his cases the prostatic enlargement was very marked. He would not think of removing a large adenomatous prostate through the perineum, and would only employ the perineal operation for prostates of small size. The speed with which it could be performed was in favour of suprapubic prostatectomy, and this was a point of importance with elderly patients.

Mr. LENTAGNE said he had often thought that a better method than the suprapubic in prostatectomy could be devised, but he was not yet converted to the perineal route; it was much more likely to lead to septic troubles than the suprapubic, as there was much more division of tissues.

Sir THOMAS MYLES said he did not quite understand what became of the mucous membrane of the bladder which covered the upward bulging portions of the prostate. Was it torn in parts or was it removed *en bloc*? Was the ideal method to leave an intact urethra and an intact bladder? He described the method by which he had carried out the perineal operation. In his opinion, if the bladder mucous membrane covering the prostate had to be divided at all it had better be cleanly removed, otherwise a ragged surface was left and pieces of the mucous membrane might subsequently obstruct the urethra.

Mr. STONEY stated that, viewing prostatectomy from the anatomical standpoint, the best method was that which aimed at removing the prostate from within the bladder. In the perineal operation the prostatic capsule was divided and the pelvic cellular tissue was exposed to septic influences.

Mr. BALL, in reply, said he had not intended to deal with the question as to which of the two operations of prostatectomy was the better. The mortality after the perineal operation was less than half that following the suprapubic, which fact alone would tend to make one employ the perineal route. Although in many cases suprapubic prostatectomy could be done with rapidity, yet this was by no means always the case. Also, he thought drainage was better by the perineal than by the suprapubic route. In conservative perineal prostatectomy the mucous membrane of the bladder over the prostatic lobes was supposed to be left intact.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY. MEETING HELD JANUARY 18TH, 1905.

PROFESSOR JOHN CHIENE, C.B., in the Chair.

Dr. W. ALLAN JAMESON showed (1) a case of psoriasis, illustrating the effect of oxydised pyrogallic acid in the treatment; and (2) two cases of lupus healed by X-rays after a prolonged period of rest.

Dr. CHALMERS WATSON gave a microscopic demonstration on the changes induced in the thyroid gland of animals by a meat diet.

Dr. ARCHIBON ROBERTSON read a paper on "The Milk Supply of Edinburgh: with Suggestions for its more Stringent Control," which will be found fully reported on page 102 of our present issue. The paper was illustrated by a number of photographs, taken for the most part under circumstances of some little difficulty, of city byres and their surroundings. It was discussed by Drs. Melville Dunlop, H. H. Littlejohn, Robertson, and James Carmichael, and a Committee was nominated to consider the question and report to the Society.

Dr. HARRY RAINY read a paper, illustrated by a lantern demonstration, "On the Nature of Friedreich's Ataxia," which will be published in our next issue. The paper was discussed by Drs. Alexander Bruce and Chalmers Watson.

THE LARYNGOLOGICAL SOCIETY OF LONDON.
MEETING HELD JANUARY 13TH, 1905.

THE following interesting cases and specimens were shown:—

Dr. STCLAIR THOMSON exhibited a case of epithelioma in a man, *æt.* 50, in whom laryngo-fissure was performed, and there was no recurrence after six months. He also showed a boy, *æt.* 14, in whom tracheotomy was performed for extreme stenosis, the larynx being extensively ulcerated, and the cords fixed in the middle line. There was a marked improvement after the operation, and the diagnosis rested between tubercle, lupus, or congenital syphilis.

Mr. DE SANTI showed, for diagnosis, a case of swelling of the left arytaenoid region, in a woman, *æt.* 35. The diagnosis was considered to be either tubercle or malignant growth.

Dr. TILLEY showed a case of tracheal obstruction. The opinion of the members was that the case was probably syphilitic.

Sir FELIX SEMON showed two cases: (1) Pharyngeal and laryngeal nystagmus in a case of probable tumour of the pons; (2) a case of inflammatory oedema of obscure origin, affecting the posterior part of the larynx, in a man, *æt.* 45.

Dr. FITZGERALD POWELL showed a case of epithelioma of the palate, tonsil, tongue and cheek, and suggestions were invited as to the effect of X-rays in such a case. The opinion generally expressed was that X-rays would not be of much value in such cases.

Dr. WESTMACOTT showed a case of ulceration of the soft palate, which had been operated upon frequently, yet was perpetually recurring. It was not influenced by iodide of potassium.

Mr. PARKER showed a case of symmetrical enlargement of the thyroid; and a beautiful series of paintings in oil, indicating diseases of the throat and larynx, were exhibited by Dr. SMURTHWAITE.

Dr. PATERSON showed a pair of laryngeal forceps for use by the direct method.

BRITISH LARYNGOLOGICAL, RHINOLOGICAL
AND OTOLOGICAL ASSOCIATION.
GENERAL MEETING HELD FRIDAY, JANUARY 13TH, 1905.

The President, Mr. NOURSE, in the Chair.

Dr. J. SIM WALLACE read a paper on "Nasal Obstruction and Mouth-Breathing," which will be found on page 104.

Dr. WYLIE remarked that the paper was really a little too deep for them to fully discuss on that occasion. He therefore proposed that the discussion be adjourned until the next meeting, and that Dr. Wallace be asked to publish it in some well-known paper so that they could all read it, and discuss it at the next meeting of the Association.

Mr. W. STUART-LOW (Secretary) seconded the resolution, which was unanimously agreed to.

The Presidential Address was then delivered by Mr. CHICHELE NOURSE, F.R.C.S.Ed., and will be found on page 101 of the present issue.

Dr. REID moved a vote of thanks to the President for his Address.

Dr. VINRACE, in seconding the vote of thanks, said they were indebted to the President for his most scholarly and instructive Address. The President had expressed very broad and liberal views in the dissertation he had put before them. He had shown them that in any endeavour to get the supremacy over laryngeal troubles they had by no means a menial task set before them. He had also hinted that their specialty was inseparable from general work. As an old individual member of the Society, it had been his (Dr. Vinrace's) pleasure to listen to the eloquence of Sir Morell Mackenzie, and they owed that deceased gentleman a very deep debt of thanks. It was within the knowledge of most of them that in the year 1887, when Sir Morell Mackenzie founded the Society, very few took an interest in it, and such subjects as were then

discussed at the meetings were tabooed and looked upon as not requiring to be considered. But at Oxford last year there was a consecutive attendance of 150 members in the particular section which their Society represented. In the days of Sir Morell Mackenzie, in 1887, the muster was only about seven or eight.

The vote of thanks was warmly accorded.

The PRESIDENT thanked those present for the kind way in which they had received his remarks.

DISCUSSION ON THE CLINICAL CASES.

A case of Nasal Polypus with Deformity was shown by Dr. W. H. KELSON:—The patient was first operated on for polypus at the hospital when *æt.* 13. He remained apparently free for a year, when the nose again became stuffy, and finally completely blocked. When seen in September last the right side was found to be filled with polypi, and the nose a good deal broader than normal. The left side was stenosed, and contained a few polypi; there was some pus on both sides; never any hæmorrhage. The nose was thoroughly scraped out in October, but recurrence had already taken place. Sections showed the polypi to be of the common mucous variety.

Dr. WYATT WINGRAVE said the case illustrated a condition of things in which granules had been formed and became polypi. A large number of polypi had been removed, but they were not the disease, but only the symptom. The polypi, if small, manifested the myxœdematous changes in the granulous tissue.

A case of Ulceration of Palate for Diagnosis was shown by Dr. WYATT WINGRAVE in an unmarried female, *æt.* 31. She complained of pain in her throat, with discomfort in swallowing, of three months' duration, with rapid loss of flesh. On examination, a shallow ulceration was visible occupying the posterior wall of the oro-pharynx and extending downwards to the laryngo-pharynx behind the faucial pillars. There was considerable accumulation of mucus on palpation. The edge of the ulcer was found to be hard and sharply circumscribed. Beyond some slight swelling of the right arytaenoid the larynx was normal. The post-cervical glands were but slightly marked. There was no history or evidence of tubercle or syphilis. Scrapings were made of the ulcer, which showed numerous epithelial squames of normal structure, pus cells, and various bacteria, including diplococci, staphylococci, bacillus subtilis, and bac. *prob.* vulgaris. No tubercle bacilli were found in several examinations. She was placed upon iodide of potassium (*gr.* xv), and in the course of one month has gained over four pounds in weight, and can swallow comfortably. The ulcer is less hard and less extensive.

Dr. VINRACE, referring to the statement, described the case as possibly one of epithelioma, and said he thought that the fact that potassium had been given for a whole month in considerable quantities rather negatived that theory, because a patient after taking so much potassium for that length of time would, he thought, be in a much more emaciated condition than was evidenced in that case.

A case of Tertiary Syphilis of the Nose associated with Epiphora was shown by Dr. DAN MACKENZIE: Male, *æt.* 35. Primary infection 2½ years ago. Treated for one year. Present illness began with watering of eyes four months ago. Nasal stenosis observed by patient about same time, but not connected with eye trouble. Has attended ophthalmic hospitals for relief of epiphora, where the usual treatment was adopted without benefit. No notice was taken of the nasal trouble. A few weeks ago he was seen by Dr. Corner, of Forest Gate, who noted the co-existence of nasal trouble, and sent him for my opinion. On examination, on December 21st, 1904, the right inferior turbinal was found enlarged and ulcerated. On the left side an ulcer fairly well back was noticed on the floor and septum, not very deep. On the posterior pharyngeal wall were two or three fairly typical ulcers. Posterior rhinoscopy showed excoriation of posterior end of right inferior turbinal. The case is shown as demonstrating the inconvenience of keeping specialisms in "water-tight compartments."

Dr. WINGRAVE said this case very well illustrated the importance of looking at the floor of the nose. They rarely found the floor involved in tuberculous conditions, and some others, but in tertiary conditions they ought to look for indications on the hard palate and the floor of the nose.

The PRESIDENT said he considered that the case was a very interesting one as illustrating the close connection between some eye affections and the nose. It brought to his mind a case of his own which he saw some nine or ten years ago. The patient was a girl, *æt.* about 21, and she consulted him on account of laryngeal catarrh. She had an obstruction of the nose from a hypertrophic rhinitis, and also a fistula over the right lachrymal sac. There was a disfiguring mark down the face from the continual trickling of the discharge. Four years before then she had an abscess at the inner canthus of the right eye. The nasal duct was probed, but the fistula had remained ever since. He performed turbinectomy, and in three months the fistula had completely healed up. He had another case. Only a few days ago he saw a man, *æt.* 44, who consulted him on account of tertiary syphilis of the pharynx and nasal obstruction. He had had a lachrymal abscess on the right side in September, 1902, and was operated on in February, 1903. The patient demonstrated to him by pressing on the sac that there was still a discharge of muco-pus going on. On examination he found that the inferior turbinal was very large. He proceeded to remove the anterior end of the inferior turbinal, and it was possible that when drainage had been established, the condition of the lachrymal apparatus would improve. Diseases of that apparatus were undoubtedly in some cases in the domain of our specialty.

The PRESIDENT showed a case of

FRACTURE OF THE LARYNX IN A MAN, *ÆT.* 65.

On November 23rd last the patient, a labourer, *æt.* 65, fell and struck his neck against the edge of a wheelbarrow. Dr. Thomas Johnstone, of Nunhead, who then saw him, elicited crepitus quite easily, and recognising the nature of the case, sent the man to the hospital. Three days later the laryngoscopic appearances were as follows:—The left arytenoid and left ventricular band were much swelled and of a dark purple colour. The left vocal cord was thick, whitish, and oedematous, and was fixed in extreme abduction. Between it and the ventricular band a bright red tongue appeared. The right side of the larynx was nearly normal. Some discoloration was visible in the trachea. There was no breach of surface. The right vocal cord moved up to the middle line, or a little beyond, but remained flaccid, and flapped to and fro in phonation; and an interval remained between the hinder parts of the cords. Externally, some swelling could be felt in the region of the larynx, but there was no emphysema. The patient's voice was hoarse, low-pitched and weak. Deglutition was painful, but there was no dyspnoea. Two days later the laryngeal swelling had diminished, and the left vocal cord was moving. The oedema extended to the right cord, and then gradually disappeared in about six days; but the discoloration of the part was still visible until the end of December.

Dr. W. H. KELSON said they all knew that one got peculiar crackling sounds much like crepitation when moving the larynx on the anterior portion of the spine. In this case which he had examined, the patient told him that he had never brought up any blood, so that it could not be a case of fracture. He did not know that the case was anything more than contusion of the larynx, or whether there was any cicatricial material or evidence of fracture beyond those sounds of crepitation.

Dr. D. A. MACKENZIE remarked that as far as possible they should endeavour to avoid their observation being attended by bias. He understood it had been said that in such cases as they were discussing there was no possible oedema of the vocal cords. This patient towards the end of the history, when the larynx was healing up, showed two very beautiful translucent

blebs on the vocal cords. He believed that in cases of the kind there had been observed such a thing as oedema of the vocal cords.

Dr. CHARLES HAWTHORNE said he would shortly report a case which was especially interesting to laryngologists. It was that of a man, *æt.* 70, who one morning, when he was getting out of bed, fell to the ground—a matter which he regarded as comparatively trivial. He admitted striking one side of his head against a chair or some article of furniture, and got back again into bed. Shortly afterwards he was seized with coughing and brought up two teacupfuls of blood. Soon his throat began to swell, and he had some difficulty in breathing. He was taken away and admitted to a hospital and placed in the physicians' ward as a case of hæmoptysis. In the course of about twenty-four hours the swelling, which had commenced at the throat, spread practically all over the tongue, and was undoubtedly a swelling due to emphysema. Dr. Middleton, the physician in attendance, called in some of his surgical colleagues, and they thought that the case must be one of fracture, and the hæmoptysis was due to surgical emphysema. It was impossible to localise the fracture, and the condition persisted, and the man died some three or four days after admission. Here was a special laryngeal fact—an attempt was made to examine his larynx without any success; the swollen condition of the larynx prevented it. At the *post-mortem* there was found in the larynx a condition which was described as a cavity underneath one vocal cord, and the cavity exposed a necrosed cartilage. It was through this degenerated cartilage that air had entered the subcutaneous tissue. The history of that patient failed to reveal any suspicion at all on the part of Dr. Middleton or his friends that the man had any disease of the throat. But Dr. Lindsay Stephen, who made the record, described the condition as quite unlike anything which he was familiar with, such as tuberculous or syphilitic ulceration. It was suggested that the condition of the larynx had taken origin in some small foreign body which had become lodged and led to gradual ulceration and necrosis, and had afterwards disappeared. That was a case, therefore, of fracture of the larynx supervening on a condition of necrosis, and first of all revealing itself by hæmoptysis and surgical emphysema. Apart from the particular appeal which the case made to laryngologists, he thought that it illustrated very forcibly that they could not cut up the practice of medicine safely into different departments, for each one of which a particular individual made himself responsible. When they took charge of a patient it seemed to him that they took charge of a whole patient. Unless they deliberately obtained the assistance of some other person with whom the responsibility was divided, it would be no excuse, when some unfortunate condition developed, to say, "That is not a part of the body which falls under our domain."

Dr. CHARLES HEATH said that in this case of fracture of the larynx it was quite possible that the right half of the cartilage was overlapping the left, so that the fracture might not be quite in the middle.

The PRESIDENT remarked that one could still detect an external deformity in the case. The accident occurred on November 23rd, or about eight weeks ago, so that considerable repair had had time to take place. When the case first came under his notice crepitation could be distinctly elicited. Dr. Johnson, who was present among them, saw the case, and when he first saw it he found that crepitation could be quite easily elicited. Moreover, when he (the President) saw the case for the first time he discovered on examination by the laryngoscope that the left cord was not only abducted, but it did not appear to be quite in the natural position of abduction; it seemed as if towards the hinder end it was pushed further than it ought to be. He based his diagnosis upon the external deformity, upon the immobility of the cord, upon the crepitation, and also upon the tremendous extravasation in the laryngeal tissues. There was no doubt that it was a case of simple and not of compound fracture. Hence

there was no emphysema, which usually happened in compound fractures. Since he had had the case he had looked up the matter and found that the mortality in such cases was very high. Out of sixty-nine cases of fracture of the larynx quoted by Durant in his paper in "Hope's System of Surgery," there were fifty-three deaths. Thirty cases were fracture of the thyroid cartilage, of whom twenty died. Almost all cases that he had come across were compound fracture, and it seemed as if that was one of the elements which produced a very high mortality. A great many of them were the result of great violence and were attended by some other injuries. With regard to the œdema of the cords, this was very interesting. There was no doubt about the cords being very much swollen and infiltrated with fluid, particularly the left cord, which was translucent and whitish. Then towards the end of the time, shortly before the œdema and extravasation disappeared, the colour of the fluid became yellowish, as if it were tinged with blood. He was very glad to hear of the very interesting case mentioned by Dr. Hawthorne.

A case of Paralysis of the Left Vocal Cord following Operation for Adenoids, in a young woman, æt. 20, was shown by the PRESIDENT.

The operation was performed on November 8th. Fifteen days later the left vocal cord was found to be immobile in the cadaveric position. It has since gradually regained its mobility; when last seen on January 4th it was adducted during phonation, although not so perfectly as the right cord. The right arytenoid still passed in front of the left. Dr. Dan Mackenzie, who first detected the paralysis, kindly examined the chest, and found both the heart and lungs normal.

Dr. KELSON asked if there was any evidence that the cord was not paralysed before the operation?

Dr. WINGRAVE said the case was one of those where it was a question as to whether they were to associate the unilateral paralysis with the operation itself as a cause. With regard to the operation being causal, they must bear in mind that the connective tissue of both arytenoids, especially the left, was distinctly swollen. It was not at all unfamiliar to them that bilateral paralysis might occur before and after an operation. It was not at all uncommon to find some disturbances of the spinal accessory nerve in persons suffering from adenoids, particularly in infants. But it was a most unusual thing to find paralysis of the bulbar accessory when the paralysis was unilateral. He was not aware that any such case had ever been recorded.

The PRESIDENT said it was quite impossible for him to say whether the paralysis was present before the operation or not, because there was nothing which led one to examine the larynx, nor did the symptoms shown at the time direct attention to the larynx. The reason why one rather inferred that the operation was the cause of the paralysis lay in the fact that, when the paralysis was first noticed, a fortnight after the operation, on that side it was more complete than it was at the present time. As to the cause, he thought that one must wait before giving his opinion.

A case of Leukoplakia (Tongue) was shown by Dr. P. H. ABERCROMBIE.

The patient, a man, æt. 63, was sent to me by Dr. Cumming Grant, on the 6th of this month, complaining of deafness. This proved to be of the obstructive type, and in the course of the usual routine examination, the tongue condition was noticed. No complaint was made of the tongue, and it caused practically no inconvenience. The dorsum of the tongue presented a large, milk-white raised, fissured patch, which had existed for about ten or twelve years. Previous to this, the patch was red in colour. In the causation of this affection, syphilis, tobacco, indigestion, alcohol, and carious teeth are said to be factors; and in this particular case the first two, at any rate, may have been operative. He had syphilis about forty years ago, and this appears to have been inefficiently treated. Such a marked example of this disease is not common, at least among the patients of a throat hospital, and I think the case is worth showing. The fact that

malignant disease may develop in tongues thus affected necessitates careful watching of the patient. As to treatment, irritation of whatever kind should be removed; alcohol, tobacco and condiments are harmful. Anti-syphilitic treatment may be necessary. Locally, a mouthwash of borax or chlorate of potassium is sedative. Defective teeth require attention, and the diet should be regulated, if at fault. Several names have been given to the disease; thus, in addition to leukoplakia, it has been called psoriasis, ichthyosis, leukokeratosis, and chronic superficial glossitis. Perhaps the best names are leukoplakia (which is descriptive of the appearances—white patches), leukokeratosis (with reference to the changes which occur in the epithelium) and chronic superficial glossitis.

Dr. WYATT WINGRAVE mentioned, with reference to Dr. Abercrombie's case, a case which had come under his observation, and which, he said, was one of no small interest, because it was an instance of fungus. There was a large mass projecting through the substance of the skin from the anterior frontal sinus, and on examination it presented all the histological characters of lymphosarcoma, that was to say, it was composed of corpuscles and relatively large round nuclei and somewhat scanty protoplasm and a small proportion of stroma.

Specimen of Rhinolith, shown by the PRESIDENT.

This specimen, weighing sixty grains, was removed from the right nostril of a young woman, æt. 21. It was lying on the floor of the meatus beyond the vestibule, and between the septum and the anterior half of the inferior turbinal body, which it had compressed. Removal was rendered easier by the fact that there were no granulations surrounding it, as is sometimes the case. There was no fetor or discharge, and the patient had complained of no symptoms. About a month before, she had noticed something white in the nostril, which had led her to consult Dr. Hughes, of Dunstable, who removed part of the concretion, and sent her to the hospital. Rhinoliths are not, in the author's experience, of very common occurrence. This is only the fourth case met with by him during the last five years. Two of the others consisted of friable deposits of large size around a nucleus formed by a piece of coal and by a sequestrum respectively. The third case was that of a woman, æt. 53, whose right nostril was occluded by a greenish-black mass, with a smooth convex surface, which lay in the vestibule and stretched it on all sides to its fullest extent. The right side of the nose bulged externally, and the septum was pushed over towards the left. The edges of the nostril all round overlapped the edges of the concretion in such a way that it appeared like a stone in a setting, and it was impossible to dislodge it without breaking it up. On the floor and sides of the cavity where it had rested, there were a number of polypoid growths, and behind, the nostril was full of polypoid

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

The annual general meeting was held at Manchester on Friday, January 20th, Sir Wm. Sinclair vacating the Chair in favour of the newly-elected President, Dr. D. Lloyd Roberts. The following office-bearers were appointed:—Vice-Presidents: Sir William Sinclair, M.D.; W. Walter, M.D., Manchester; Owen Bowen, M.R.C.S.; Arthur J. Wallace, M.D., Liverpool; J. B. Hellier, M.D.; A. C. F. Rabagliati, M.D., Leeds; John W. Martin, M.D.; Percival E. Barber, M.R.C.S., Sheffield. Honorary Treasurer—E. Octavius Croft, M.D., Leeds. Honorary General Secretary—W. E. Fothergill, M.D., Manchester.

APOPLEXY OF THE OVARY.

Dr. HAWKINS AMBLER showed two specimens illustrating this condition. The first was from a lady, æt. 41, who had violent abdominal pain accompanying influenza two weeks after an unusually profuse menstrual period. The uterus was enlarged and emitted a sanious discharge. The left ovary was represented by a blood cyst the size of a hen's egg, a chocolate-coloured putty-like mass being enclosed in a shell of altered ovarian tissue. The right ovary was

cystic, inflamed and adherent. The second was from a patient, *æt.* 35, who had had severe menstrual pain for a year, with various attacks of pelvic peritonitis. An oval cyst was found adherent to the left side of the uterus, the colon and the rectum. It was as large as an orange, and was filled with blood clot and fibrin and represented the left ovary.

UTERINE SOUFFLE.

Dr. J. B. HELLIER described two cases illustrating the production of uterine souffle. The first was one of uterine myoma, the size of a three months' pregnancy, which produced a loud bruit and also a palpable thrill. After removal, the uterus was injected, showing the presence of a large uterine artery and large venous sinus on the right side. The second case was one of retro-peritoneal sarcoma which pushed the uterus against the abdominal wall in the hypogastric region. Over the uterus, which formed a visible prominence reaching $3\frac{1}{2}$ inches above the pubes, there was a soft souffle which disappeared after the enucleation of the tumour.

The PRESIDENT, Dr. Lloyd Roberts, showed a liver enlarged by metastatic deposits, the primary lesion being cancer of the head of the pancreas. A lobe of the liver divided from the main mass by a deep sulcus extended into the right side of the pelvis. A point in diagnosis was thus raised, as during life the condition suggested the presence of a tumour of pelvic origin co-existent with enlargement of the liver.

The Operating Theatres.

GUY'S HOSPITAL.

SEQUELA OF A PYLORECTOMY.—Mr. ARBUTHNOT LANE operated on a patient, a man, *æt.* 54, from whom he had excised a cancerous pylorus three years and four months previously. He closed the pyloric and duodenal orifices and performed a gastro-jejunostomy. The patient did very well till a month previous to his admission, when he began to complain of distension of his abdomen and a feeling of sickness; these symptoms were quite different from those produced originally by the pyloric obstruction, and there was distinct distension of the small intestine and of the large as far as the umbilicus. Above the umbilicus a hard mass could be felt. On opening the abdomen the obstruction was seen to be due to the presence of a dense cicatricial cancerous mass in the meso-transverse colon. This pulled on the colon, which was attached to the abdominal wall, and contracted its calibre very considerably. The mass with the transverse colon was removed, the ascending colon being drained and the splenic flexure closed. The stomach was perfectly healthy and functioning well. On this occasion, two weeks after the removal of the large bowel, Mr. Lane divided the ileum about six inches to the proximal side of the cæcum and established a communication by lateral anastomosis with the sigmoid flexure. Mr. Lane said there was no evidence of any secondary growth in the liver and the infection of the transverse colon was by direct extension from the cancerous gland in the mesentery.

CHRONIC ULCERATIVE COLITIS.—FISTULOUS APERTURE IN END OF ILEUM.—OPERATION TO CONNECT ILEUM WITH SIGMOID.—The same surgeon operated on a patient who a year before had suffered very severely indeed from acute ulcerative colitis. Fearing that he was dying his medical attendant picked up the end of the ileum through a hole in the right groin and drained it, so diverting the faecal matter from the large intestine. This operation, though it certainly saved the patient's life in that the symptoms were immensely relieved by it, left the patient in a condition of chronic ulcerative

colitis. When he was admitted all faeces passed through the hole in the groin, while he discharged at intervals a quantity of foul-smelling mucus from the anus, over which he had no control whatever; he was miserably thin. Mr. Lane made a hole in the left groin and explored the viscera. He found the whole of the large intestine shrunken to the thickness of a lead pencil, and of a livid colour. The sigmoid presented the same appearance, so that it was absolutely out of the question to attempt to establish any communication with it, partly on account of its minute size and partly because of the rotten state of its walls. By exerting much traction on the rectum it was found that a portion of it was sufficiently dilated to make an operation possible, and after great difficulty the ileum, after it had been cut through, was united to this piece of bowel.

Mr. Lane said that in an acute case of ulcerative colitis in which he had operated recently the bowel was so inflamed and vascular, and its walls so friable, that he was unable to connect the ileum with the sigmoid as he had intended. The course pursued in the case just operated on—namely, of establishing an aperture in the right groin through which the whole of the faecal contents escape from the ileum—is probably, he thought, the best mode of treating this condition. The large bowel may also be treated locally by flushing it very effectually through the distal portion of the ileum. Fortunately the patient did very well, and he has not only been relieved of the distress consequent on the escape of irritating material from the ileum, but he has to some extent regained control over the sphincter. His general condition is improving steadily.

NORTH-WEST LONDON HOSPITAL.

OPERATION FOR LARGE OVARIAN CYSTOMA.—Mr. JACKSON CLARKE operated on a patient, a married woman, *æt.* 43, tall and thin, with a weak voice and cough from slight chronic bronchitis. The abdomen was distended in the whole of its vertical and lateral extent. Two years before admission patient had noticed pain in the lower part of the abdomen, and for the last three months she had been aware of increasing enlargement and discomfort. She had been twice tapped, obtaining temporary relief; large quantities ("several gallons") of fluid having been drawn off. Each time the abdomen refilled rapidly. On admission, the patient looked ill; her pulse was 88, the abdomen was symmetrically enlarged and dull everywhere, save over the right flank. Percussion note was unaffected by position, and there was a marked thrill, especially in the uppermost part of the abdomen. The menses had been irregular for some time. Vaginal examination showed the uterus to be slightly less movable than usual, but there was no bulging felt. The patient complained of a good deal of pain in the rectum, where some piles were found. The usual median incision was made and the tumour was found to be adherent to the peritoneum by a broad surface. An opening gave vent to a large quantity of viscous blood-stained liquid. Successive cysts were opened and evacuated; some contained clear, others variously-coloured, liquid. The incision in the parietes was then extended upwards till a part was reached midway between the xiphoid cartilage and the sternum, where the peritoneum was not adherent; a finger was passed in and the tumour was separated from the abdominal wall and the opening in it securely tied up. Before the tumour

could be brought out through the wound very numerous adhesions to the stomach, duodenum, omentum, spleen and small and large intestines had to be clamped and divided. The pedicle was the left broad ligament, and this was secured by interlocking sutures and the tumour removed. The adhesions were then tied off and cut short, and the abdomen dried. The wound was stitched in three layers—peritoneum, aponeurosis, skin—and a good packing of cotton wool was placed under the bandages to hold the over-stretched and thinned parietes to the viscera, which now filled but a fraction of the potential space of the abdominal cavity. Mr. Clarke said that the case afforded still another instance of the close resemblance that there is, superficially between the symptoms of ascites and cysts in the abdomen.

For a week after the operation patient's cough was slightly worse, and she was restless for the first two nights. Apart from this she had no trouble. The tumour was a typical ovarian cyst-adenoma with a fair amount of solid tissue.

REGISTERED FOR TRANSMISSION ABROAD.

The Medical Press and Circular.

Published every Wednesday morning, Price 6d. Post free, 5½d.

ADVERTISEMENTS.

ONE INSERTION:—Whole Page, 25 0s. 0d.; Half Page, 12 10s. 0d.; Quarter Page, 6 5s. 0d.; One-eighth, 3s. 6d. Considerable Reductions from the foregoing scale are made when an order is given for a series of insertions. Terms on application to the Publisher.

Small announcements of Practices, Assistantships, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

SUBSCRIPTIONS.

Subscriptions may commence at any period of the year. If paid in advance the cost is only 21s. per annum, post free. An edition is printed on thin plate paper for foreign and Colonial subscribers at 21s. per annum, post free, if paid in advance, or 23s. 6d. credit rate.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, FEBRUARY 1, 1905.

THE METROPOLITAN SUNDAY AND KING EDWARD'S FUNDS AND THE SMALL HOSPITALS.

IN our last issue we laid certain considerations before our readers with regard to the Western Skin Hospital, to which no grants have been awarded by either the Metropolitan Sunday or the King Edward's Funds. We showed that it was one of the oldest special hospitals in the United Kingdom; that during its long career its affairs had been administered with the most vigilant and unceasing economy; that its absolute integrity and honour had never been once called in question, and were, moreover, vouched for by the names of those answerable for its administration, such as, for instance, that of the present Honorary Treasurer, the Hon. Harry Lawson, M.P. In spite of these conditions the Western Skin Hospital is subjected year after year to the injurious humiliation of being excluded from the grants of two out of the three Metro-

politan hospital funds. We had hoped that Sir Henry Burdett, who in the pages of the *Hospital* has made some show of answering our criticisms on the administration of the Sunday and the King Edward's Funds, would have furnished a clue to the mystery. Our hopes have been doomed to disappointment: even his previous plan of pointing out minor errors of detail, while at the same time evading the questions of principle, has been on this occasion denied to us. Nor is much further light to be gained by turning to the attitude of the two Funds with regard to other London skin hospitals. The Blackfriars Hospital for Skin Diseases in Stamford Street, for instance, is known all over the world as one of the famous, and, indeed, classical centres of medical specialism. Its career has been no less honourable than its work has been scientific. Yet this hospital is consistently boycotted by the Sunday and the King Edward's Funds. If this be done on the ground that the premises are unsuitable for hospital purposes, it may, on the other hand, be reasonably urged that the bulk of the work is among out-patients, and that the wards answer well enough to the test of the ratio of in-patient mortality—a sufficiently searching practical test. In a word, the exclusion of the Western and the Blackfriars Skin Hospitals from the grants of the Hospital Sunday and King Edward's Funds, in our opinion, demands instant explanation if the public is to trust the wisdom and impartiality of those funds. Let us now turn to St. John's Hospital, to which repeated grants have been made by the Sunday and one recently by the King's Fund. Without wishing to rake up past occurrences, it is notorious that within comparatively recent years grave public charges have been made against the management of the hospital—charges that have not been disposed of satisfactorily either in the law courts or elsewhere. Nor has the subsequent history of the institution been of a kind calculated to re-inspire confidence. The definition of the word “hospital” has no doubt engaged the attention of the Funds from time to time. Have they ever seriously inquired, we wonder, what is the claim of St. John's Hospital to that name? On January 15th, 1890, St. John's was registered as a Friendly Society. For some reason or other the management became dissatisfied with that arrangement, and in 1900 they wound up the Society and enrolled themselves as a limited liability company. Why it should be desirable for any self-respecting and honourable medical charity to take either step must be to most men an unfathomable mystery. At present the Board of Management is self-appointed and autocratic. The so-called governors have practically no power in the affairs of the hospital. One member of the honorary medical staff, we notice, is a director of this strange company. We venture to ask if the Hospital Sunday and the King Edward's Funds were fully acquainted with this state of affairs when they devoted the money of the charitable

public to a hospital that feels constrained to adopt the machinery of commercial undertakings in order to administer to the wants of the sick poor? Yet the Sunday and the King Edward's Funds can find money for this company in spite of its past history and its present curious constitution and its unauthorised management, while other skin hospitals, like Blackfriars and the Western, with untarnished histories, are sent empty away. It seems certain that unanswered charges against the management of a hospital in the columns of *Truth*, however often repeated, do not disqualify that charity from the awards of the Funds. Otherwise the Queen's Jubilee Hospital would have fared badly, instead of receiving a fair share of grants. It is to be hoped that the points raised in connection with the small hospitals will be seriously considered by the Councils of the Hospital Sunday and the King Edward's Funds. Our criticism is offered in full recognition of the splendid work achieved by those bodies. It is conceived, we trust, in a spirit of fairness and of public-spirited love of justice such as are known to appeal to the unflinching practical wisdom of the King and of the Prince of Wales. In offering these criticisms we are glad to think that the Funds have not tied our hands in any way by including the Editor of THE MEDICAL PRESS AND CIRCULAR in the list of Councillors, where medical and nursing journalism is already amply represented by the *Lancet*, the *British Medical Journal*, and the *Hospital*. Should the Funds appoint committees of inquiry into the Orthopædic Hospital Amalgamation, the St. John's Hospital Constitution, and other matters raised by us in the present series of articles, we can as an independent journal place a number of interesting documents at their disposal.

POISONING BY WOOD SPIRIT.

A LITTLE over twelve months ago we drew attention to a series of cases of grave or fatal poisoning in America resulting from the use of methyl alcohol. Since that time the number of cases has increased so largely that it is worth while again to point out the great danger to the public from the careless use of this spirit. In these countries one but rarely hears of anyone drinking methylated spirit, for the taste and odour are so unpleasant as to be deterrent, while grain alcohol is, unfortunately, so easily got as to be within the reach of all who seek alcoholic stimulation. In the States, however, where in many districts the sale of grain alcohol is either altogether prohibited or fenced round with many difficulties, people are prone to look for some substitute. In addition, during the last few years it has become customary to deodorise methyl alcohol in order to make use of it in various culinary and toilet preparations, such as essence of lemon, bay rum, "colonial spirits," witch hazel extract, and others. When made up in these elegant forms there is little doubt that methyl spirit may be used for the adulteration of whisky and other forms of ethyl alcohol. In the immense majority of the cases of poisoning

the persons affected have been of alcoholic habits and have taken to the drinking of the methyl spirit, either from a liking for it or as a substitute for unattainable ethyl alcohol. The fatal dose is usually from four to eight ounces, though serious effects have followed a dose as small as half an ounce. This being so, we need not wonder that poisoning sometimes occurs by inhalation of the vapour, and sometimes by absorption through the skin. For instance, persons who had used alcoholic washes or liniments were found suffering from optic neuritis, and a similar lesion has been found in tradesmen who had to use methyl solutions in the arts. In manufactories where large quantities of methyl spirit are used it has, therefore, been found necessary to arrange an extra supply of fresh air to the workers. The most constant symptoms of methyl poisoning are mild intoxication followed by severe headache, gastric pain, retching, dilatation of the pupils, and partial or complete blindness. In the most serious cases this sequence is followed by dyspnoea, coma with stertorous breathing, and death. The toxic amblyopia is of all these symptoms the most constant and important, since even when recovery takes place, atrophy of the optic nerve is likely to follow the neuritis, and a permanent blindness is the result. The immediate cause of death in fatal cases is not quite clear, though respiratory paralysis sometimes precedes circulatory failure. It is thought that the toxicity of the drug may be greatly increased by the production of formates in the body by the decomposition of the methyl alcohol; and formates have been discovered in the urine. Whatever be the exact pathology of the condition, there is no doubt that the intense toxicity of methyl alcohol calls for extreme caution in its use. It is, moreover, the duty of the profession to see that the public are properly instructed on the point.

UNDERFERD CHILDREN.

THERE is a wonderful tendency in the human mind to worship its own creations. In the savage and lowly-civilised this tendency shows itself in stark idolatry; in their more developed descendants it assumes the form of reverence for laws and official systems. Whilst a proper regard for the organisation of the State is a commendable trait in a nation, it is always apt, unless incessantly controlled and checked, to lead to undue worship of the form and undue regard for the aim for which the organisation exists. Familiarity with the institution tends eventually to obliterate the notion that the whole aim of the army is to fight, the law to administer justice, and the school to educate. If, however, the ultimate objective of a system be always kept clearly in view, it should be obvious to the meanest intelligence that unless the conditions necessary for efficiency are provided, the system itself becomes a mere fetish. Now, in all the embittered controversies on the religious question in elementary schools, and the only less heated ones on the curriculum to be

followed in them, the fact that it is absolute waste of time to teach children religion, arithmetic, or physical exercises unless they are in a fit state to learn has been most strangely overlooked by the partisans. Receptivity in the pupil is a necessary antecedent to instruction of any kind, and educationalists would do well to appreciate that elementary, cardinal, and obvious fact. The child who is mentally deficient, physically ill, or actively hungry is not in a state of receptivity, and the sooner he is eliminated from the school class, the better will it be for the teacher, the class, and himself. Mental deficiency and actual illness are more or less already provided for or guarded against, but the hungry child is officially non-existent. He is of school age and he can walk; therefore he is hunted to school by diligent attendance officers, and there left for his teacher to make the best job of him he can. The sheer stupidity of this routine performance is fortunately beginning to strike those educationalists who prefer furthering the mental and physical welfare of the child to winning ephemeral triumphs at by-elections. An army, one knows, moves on its stomach; a child is educated on the same viscus. Given average or even good mental and physical powers, there can still be no instruction conveyed to a child till his stomach is lined. If reasonable nutrition were made a necessary antecedent to school-teaching, there would, at least, be a prospect of some good accruing to the unfortunate object of educational experiments. The extent to which under-feeding, as it is euphemistically termed, exists is difficult to ascertain, but all medico-educationalists are agreed that in the elementary school children in large towns the proportion is sadly high. Dr. Eichholz, in his evidence before the Physical Deterioration Committee, put the number in London at 122,000, a proportion of no less than 16 per cent. of all London pupils. Dr. Kerr, of the London School Board, puts the number at only 10,000, but he estimates that 10 per cent. of the children are incapable of receiving benefit from school-teaching from starvation and similar causes. But whether the total be 122,000 or 10,000, it may unhesitatingly be said that the public money expended on teaching them is utterly and irretrievably lost. Dr. Eichholz, by taking the children in three schools in typically poor neighbourhoods, has shown that proportions of 74 per cent. in Notting Hill, 72 per cent. in Lambeth, and 69 per cent. in Finsbury, never rise above the three lowest school standards, whilst in the bottom class of all it is no uncommon phenomenon to find half-starved children of eleven, twelve, and even thirteen years of age. General insanitary conditions play a rôle, doubtless, in producing this mental obtuseness, but it cannot be allowed to be a large one. The prime and essential factor is the want of adequate nourishment. The difference that can be wrought in the general intelligence by providing sufficient, though not a redundant, quantity of food has been shown by the enlightened experiments of Dr. Hall, of Leeds.

Out of his own pocket this philanthropic gentleman started a scheme for providing cheap meals for a number of the poorest children, and in the short space of a fortnight was able to obtain an amount of physical growth and general improvement that was astonishing. By going carefully into the matter he found it possible for the ridiculously small sum of a penny to provide a wholesome meal for a child if fed in the school building and waited on by willing elders, and by two such meals a day to a hundred children he obtained in the first ten weeks an increase in weight per child of from one to five pounds. Certain voluntary agencies are doing something already in London to serve the poorest children through the coldest months of the year with one good meal a day, but far more than this is needed. The question of parents evading their natural responsibilities has, of course, to be faced, but until the children are fit to be taught it would seem elementary economy to suggest giving them bread before, or if necessary in place of, instruction. The question is ripe for the pen of a Dickens to do for the elementary school child what he did for the middle-class boy by his sketches of life at Dotheboys Hall and Salem House.

Notes on Current Topics.

The Edalji Case.

OUR readers will remember the steps taken by THE MEDICAL PRESS AND CIRCULAR in November, 1903, to bring about a revision of the trial of Mr. Edalji, the young Birmingham solicitor who was sentenced to seven years' penal servitude in the October of that year for maiming a pony at Great Wyrley. We felt at that time that the evidence on which the conviction was obtained was far from conclusive, and, moreover, that if Mr. Edalji were actually guilty of the crime with which he was charged, the act indicated a degree of mental disease that should have sent him to the asylum rather than to prison. A petition was started by this journal; and the signatures of a large number of medical men engaged in every branch of practice having been obtained, the document was forwarded to the Home Secretary. Beyond the usual official acknowledgment, nothing further has been heard. Since then we have commented from time to time on the matter, but without appreciable result. Now we are glad to see that our able and vigorous contemporary, *Truth*, has taken the matter up on its own account, and, after going carefully into the evidence and weighing each item with judicial impartiality, sums up its articles strongly in favour of the condemned man. As the Beck case is being cited *ad nauseam* by advocates appearing for every prisoner in the country, we are unwilling to do more than refer to it in this connection. The investigation in that case showed that the Home Office is not only fallible like all other human agencies, but at times even stupid. We feel we have no guarantee that our petition even reached

the heads of the department, and none that the evidence in the trial has been reviewed by anyone with legal training. We, therefore, join with *Truth* in demanding that the whole case shall be reviewed afresh by trained and impartial minds. It is difficult to escape the conclusion that either Mr. Edalji is an innocent man, as the continuance of the outrages after his imprisonment suggests, or he is a poor madman who should be cared for in an asylum.

Fresh Air and Phthisis.

DURING the past five-and-twenty years there have taken place in ordinary practice many changes in the treatment of consumptive patients. We all remember when it was considered the perfection of treatment to guard the patient against every chance draught, and when a chill was regarded as the most dangerous of occurrences. Even at that time, however, there were a few here and there who cried out that fresh air was not only harmless but beneficial to consumptive patients, and practised their doctrine with success. A few years ago all this had changed and opinion had shifted so much to the opposite extreme that fresh air had actually come to be regarded as a specific cure for phthisis. The era of sanatoria had begun, and a general idea prevailed that not only was phthisis curable, but that every case was so. What is our position at present? It is impossible to give any definite judgment as to the value of sanatorium treatment, for the time of trial is still too short, and the figures are difficult of collation. Nevertheless, it is safe to say that, although sanatorium treatment has fallen far short of the wild hopes held five or six years ago, it is certainly the best method of treating phthisis. We believe, too, that while the cult of fresh air is becoming saner in its evolutionary tactics, it is being recognised that its usefulness is capable of wider application; for not only in phthisis, but in all other diseases of the lungs—pneumonia, whooping-cough, broncho-pneumonia—has fresh air been found to have a beneficial effect. The belief in fresh air as a specific for tubercle is waning, but its importance in therapeutic hygiene is becoming more recognised every day.

Women and Quack Doctors.

WE commented some months ago on the excellent work which an American paper for ladies, *The Ladies' Home Journal*, has been doing by its crusade against the use of secret medicines. We are glad to see that in a recent number the writer of the previous articles, Mr. Edward Bok, is continuing his task by an exposure of the methods of the advertising doctor who gives his "personal advice" to all and sundry who care to apply. It is hard to believe that any woman who reads the article will ever allow herself in future to be gulled by one of these ravenous impostors. Mr. Bok gives, from inside knowledge, a detailed statement of the manner in which one of these medicine-businesses, which makes a special profession of "personal attention" and "confidential commu-

nications," is conducted. The advertisements issued contain references to "the private diseases of women," "special troubles of the sex," and so on, and an assurance of absolute privacy with regard to correspondence is given. "The Great Doctor," however, whose "personal advice" was to be given, spends nearly all his time yachting or in the country, and is in reality a man who had failed to become a regular physician. Letters asking for advice are opened by a score or so of "mail-openers," and a foreman having marked a number on each letter, the reply corresponding to that number is despatched. The "chemist" of the establishment had entered it a few months before as hall porter, but has been promoted. The medicine supplied is nearly half alcohol, so that most of the unfortunate patients become fond of its use. *The Ladies' Home Journal*, both by the publication of such articles and by the conduct of its advertising columns, offers an example which might be well followed by our society journals at home.

Cremation.

It is now almost twenty years since the first crematorium in Great Britain was opened at Woking. At that time the movement to substitute cremation for earth-burial as a means of disposal of the dead met with the bitterest opposition. Public opinion looked on the proposal as little less than sacrilegious, and clerics denounced it in round terms from their pulpits. At the present day all this opposition has died out, and the advocates of cremation have to complain rather of apathy on the part of the public than of any active hostility. There is no doubt, however, that the idea is gaining ground among the better educated members of the community; and the number of cremations annually performed increases year by year. There are at present nine crematoria in the Kingdom, of which eight are in England and one in Scotland, while, naturally enough, considering the conservatism of the inhabitants of that island, there is none in Ireland. This year two new institutions will be added to the number—one at Ilford, and one at Bradford. The number of cremations performed each year is now nearer six than five hundred, and is likely to increase in the future. Indeed, one of the principal obstacles at present to the more general adoption of cremation is the expense attached, and this can only be materially reduced as the process gains in popularity.

An Operation for Pruritus Ani.

AT first thought one is inclined to regard a radical operation for the relief of pruritus ani as somewhat heroic treatment, but no one who has seen a really grave case is likely to concur in this opinion. There is perhaps no suffering more trying to the spirits of a patient than the constant and unremitting annoyance caused by the itching of this disease, while the mental misery is only increased by the fact that the physical health of the

patient is usually unaltered in other particulars. In its general effect on the patient's mental condition it resembles trifacial neuralgia, and it is now fully recognised that this disease demands and justifies, in cases of extreme severity, the most far-reaching operative measures. Various suggestions have been made as to the best surgical means to be adopted for relief of pruritus ani, and Sir Mitchell Banks was in the habit of destroying the superficial layers of the skin by the cautery. Other surgeons have practised the complete excision of the affected skin, as has also been done in the similar condition of pruritus vulvæ. A neater and, we think, more scientific method of treatment is that recommended by Sir Charles Ball in a recent paper. He suggests the section of the sensory nerves of the part, and he performs the operation by carefully separating the skin around the anus from the underlying tissues, and thereby rendering it anæsthetic. The operation has been practised with complete success in several cases, the relief having lasted up to the time of writing, a period in some cases of a couple of years. Sir Charles Ball suggests that where this operation fails, it should be considered whether it is not advisable to excise the ganglia of the posterior roots of the third and fourth sacral nerves.

Gonorrhœal Rheumatism in Infancy.

A RARE condition was reported to the Rouen Medical Society by M. Magniaux at a meeting this month. (a) A woman suffering from a leucorrhœal discharge was confined, and her infant soon afterwards developed purulent ophthalmia in both eyes. This condition in the infant was succeeded by synovitis of the extensor tendon-sheaths of the left hand, of the extensor and flexor tendon-sheaths of the left foot, of the left tibio-tarsal joint, of the left shoulder-joint, and some periostitis of the sternum. Unfortunately no bacteriological examination was made of the vaginal discharge of the mother or the pus from the child's eyes, but taking the clinical history and manifestations together, M. Magniaux points out that there can be no reasonable doubt but the child was the subject of the disease generally known as gonorrhœal rheumatism. Acute rheumatism is notoriously uncommon in the newly-born, but gonorrhœal rheumatism is less rare. M. Magniaux has collected fifteen cases from literature in which the conjunctival infection alone was the starting point of a generalised infection by the gonococcus, and he considers it impossible to draw any other conclusions from the case under notice. Happily the prognosis of gonorrhœal rheumatism is much brighter in infants than in adults, and in the instance mentioned by M. Magniaux the lesions all subsided completely.

Medicine in the Novel.

WE are accustomed in reading fiction to come across clinical descriptions of diseases which puzzle the sharpest diagnostic acumen, and we have long

ago given up attempting to solve such enigmas. We have ceased, too, to wonder at the frequency with which heroes and heroines suffer from "brain fever," a title unknown to the Royal College of Physicians. But, when a medical man writes a novel, we might expect him at least to exercise some little care, and, for the sake of his discarded professional reputation, to write accurately on matters of medical bearing. It is, therefore, more in sorrow than in anger that we find fault with our quondam brother, Sir Conan Doyle, for some of his recent writings. In "The Adventure of the Golden Pince-Nez," Sherlock Holmes makes the statement, shocking to every oculist, and, indeed, to all of us, that a short-sighted lady wears convex glasses "of unusual strength," and is "really helpless without them." It is disappointing that a man of the great detective's perspicacity should be permitted to fall into a blunder which will obviously put him on the wrong track, but it is disconcerting to our professional pride that his friend, Dr. Watson, is unable to set him right. Again, in "The Adventure of the Second Stain," we learn that a blood-stain, several days' old, was a brilliant "crimson." This should have raised some doubts in the mind of a man of such experience of blood-stains as Mr. Holmes, not to speak of Dr. Watson, and surely Sir Conan Doyle must have seen some blood-stains during his South African experiences, even if he has quite forgotten his student days. However, Kingsley, who liked to be regarded as a naturalist, once addressed the lobster as "cardinal of the seas"!

Undesirable Immigrants.

THE glass of fashion in the treatment of consumption is a kaleidoscopic one. Sir Samuel Wilks, in an entertaining article the other day, recounted the number of crazes in dealing with pulmonary tuberculosis that he has seen in vogue in the course of his long life. The earliest that he could remember was the treatment of pumping hydrogen sulphide up the rectum, and the latest the fresh-air mode. The former used to be wittily described by a popular lecturer at one of the London hospitals as appearing to him to be fashioned on the principle of sending coals to Newcastle, whilst the latter is still with us. One phase that it may be hoped will soon be buried in oblivion is that of posting off bad cases to the Southern hemisphere "to give them a last chance." The last chance might often be described as a *coup de grâce*, for medical men at the Cape and in the Antipodes are continually complaining of the number of hopeless cases that are landed on their shores to die. This form of dumping is resented by our Colonies as much as the dumping of tin-plates or steel rails is by our tariff-reformers; and now that sanatoria are "dotted about through the length and breadth of the land," it may be anticipated that the consumptive will be retained for the home market in greater numbers than before. Even the worm will turn, and Mr. Seddon is as little like a worm when he is roused as can

(a) *La Méd. Moderne*, January 8th, 1906, p. 22

be imagined. A deputation waited on him at the beginning of the year to ask for a Government grant towards a home for consumptives; it seemed to have departed with something like a flea in its ear. Mr. Seddon said that every steamer that came to New Zealand brought consumptives, many in advanced stages, and that the Colony was being used as a dumping ground by Great Britain. He threatened to take strong measures if the process of immigration was continued, and Mr. Seddon is known to be as much a man of action as of words. It is well for medical men to bear in mind the great responsibility they incur in sending patients in any but the very earliest moments of the disease to distant countries, especially to such as are not able to provide them with all the amenities of life to which they have been accustomed at home.

Attendance in Confinement.

WITH every wish to recognise and act up to the spirit of charity that pervades our voluntary hospital system, it cannot be a matter for wonder that attendance on the unspeakably filthy foreigners that throng the doors of some of our East End charities is a considerable trial to the medical men and nurses concerned. The discomfort of the situation is not lessened by the manners and customs of many of these aliens, who treat the charity dispensed to them as though it were their birthright, and many stories come to our ears of the annoyances that are met with at their hands. One of the students working in the extern midwifery department of the London Hospital was recently subjected to an outrage of a particularly offensive character the other day. He was called at night to a confinement in some buildings in Whitechapel, and finding that some hours would elapse before his services were needed, told the husband that he was going back to the hospital and would return later. This individual, by way of showing his appreciation of the gratuitous services rendered to his wife in time of trouble, promptly locked the student in the room and kept him there for three and a half hours till the baby was born, while for all he cared another woman might have been requiring the student's attendance. The alien question is a sufficiently serious one in itself, and the difficulties of solving it by a statesmanlike means will not be lessened by actions of this kind. If the East End foreigners excite prejudice against themselves they are likely to find that the legislation that is pending with regard to them will not be so lenient as many desire it should be.

Syphilis in Animals.

THE researches of Metchnikoff and Roux into the etiology of syphilis are being energetically pursued, and some of their more recent results, both positive and negative, are of great importance. It has now been established by these inquirers that the syphilitic *contagium vivum*, whatever be its exact nature, is not of very minute size, for it

is incapable of passing through a Berkefeld filter. Most of the pathogenic bacteria are similarly stopped by this filter, but there are certain micro-organisms, and these not of ultra-microscopic size, which can pass it. Metchnikoff and Roux show, also, that the syphilitic virus is destroyed by heat, an exposure to a temperature of 50° C. for one hour rendering it incapable of producing infection. Glycerine, however, has, as far as has been observed, no effect on its pathogenicity. The organism is probably non-motile, for no movement could be made out in a fluid containing it in suspension. Several attempts have been made to produce a vaccine either by artificial attenuation or by simple diminution of dose, but so far results have been entirely negative. The difficulty seems to be that, while some species of monkeys, notably the chimpanzee, possess a susceptibility to syphilis similar to that in man, in other species susceptibility is entirely absent. Metchnikoff is anxious to find some species which is inoculable by syphilis but at the same time possesses sufficient resistance to develop only local lesions and not suffer general infection.

Sir Frederick Treves' Book.

IT is given to but few members of the profession to be able to retire at a comparatively early age with eye undimmed and natural force unabated. And to those who can there are even less seldom added a European reputation and an ample competency earned by unquestionable professional pre-eminence. Such, however, is the enviable position of Sir Frederick Treves, and true to the instincts that have built up his success he finds his diversion in a change of work. It was generally known that his recent tour round the world was to be productive of a book on his experiences, and now that book has been published there are few, we think, who will not take pleasure in reading the comments of so acute an observer on the phenomena that he encountered. With all eyes turned to the East, it is to Sir Frederick Treves' impressions of Japan that people will look with the keenest interest, and it is noticeable that he thoroughly endorses what Miss McCaul has recently said about the efficiency of the Japanese Red Cross Society and military medical arrangements. Coming on top of Sir Frederick's experiences in South Africa, it is particularly significant that he is able to say of the Society that it is the most remarkable and efficient of its kind in the world, and that whereas in the late war this country lost by death 13,250 soldiers from disease, most of which was preventable, the Japanese under conditions of greater rigour, and in operations on a far larger scale, have lost but a fraction of 1 per cent. from similar causes. The Japanese nurses would seem to be not the least marvellous product of a rejuvenated civilisation. The dexterity of her small hands in using a pair of forceps "only a prestidigitator could mimic, and only a life-long use of chop-sticks could explain." But even Japan is not free from quacks, and from Sir

Frederick's account they yield nothing in blattancy and chicanery to our own worthies.

Bread Substitutes in Diabetes.

THE chief difficulty in the treatment of diabetes mellitus lies in adjusting the diet to the particular case in hand. It is bad enough for the patient to be deprived of certain dishes which, from long use, he has learned to look upon as almost a daily necessity. The trouble is far more real in the case of the poor, to whom ordinary white bread and potatoes are indispensable, and for which there is practically no cheap substitute. It is a well-known clinical fact that the worry induced by the enforced abstinence from some customary article of food does as much harm to the diabetic as its ingestion in moderate quantity. At any rate, there is an increase in the quantity of sugar passed when a patient begins to pine and fret after a slice of bread-and-butter, which he has been told by his physician on no account to take. The gratification of an earnest longing of this sort, within limits, will probably do him more good than the most expensive, but unpalatable substitute. Many of the so-called "diabetic," breads and foods undoubtedly contain quite an appreciable quantity of carbohydrates, whereby their virtue is, of course, correspondingly impaired. There are very few that are really liked by patients, and the price of the majority militates greatly against their general consumption. Dr. R. T. Williamson, (a) of Manchester, classifies the bread substitutes into (1) the vegetable albumens, such as gluten, roborat, and aleuronat; (2) nuts, including the almond and the cocoanut; and (3) the milk-albumens, such as plasmon, protene, and casoid. These latter contain 82 per cent. of proteids, and they are practically free from carbohydrates. The nut-tribe are apt to give rise to dyspepsia, owing to their contained fat. The best plan appears to be to get the patient to try one after another until he hits upon one which suits both the palate and the pocket. Home-made preparations made from one of the starch-free flours are often more satisfactory than the bread as usually sold.

PERSONAL.

It is officially announced that the following additions to the list of the Honorary Medical Staff for King Edward VII.'s Hospital for Officers, appointed by the Prince of Wales, President, have been approved by the King, as Patron:—Mr. Watson Cheyne, M.B., C.M.Edin., F.R.C.S., F.R.S.; Mr. Pearce Gould, M.S., F.R.C.S., Honorary Surgeons; and Dr. Bruce Porter, Honorary Physician.

TOWARDS the cost of the whooping-cough wards, &c., now in course of erection, the trustees of the estate of the late Mr. Siegfried Rudolf Zunz have offered to make a grant of £3,000 to the East London Hospital for Children at Shadwell, on condition that a ward be named the "Annie Zunz" ward, and that the balance of the money required to complete the building be obtained by June 30th next; £10,000 in all is still required.

We understand that £157 10s. was realised by the

(a) *Practitioner*, January, 1905.

annual ball of the Royal Isle of Wight Infirmary and County Hospital, which was attended by Princess Henry of Battenberg, President of the hospital.

MR. W. THORBURN has been elected President of the Manchester Medical Society for 1905.

MR. WALTER WHITEHEAD has been elected a member of the Court of Governors of the University of Manchester. The Manchester Edinburgh University Club has elected Professor A. H. Young, of Manchester, President for the year. It is expected that Sir William Turner, K.C.B., Principal of the University of Edinburgh, will be the guest of the club at the next annual dinner.

ON January 27th Sir W. H. Preece opened the new electro-therapeutic department recently added to the Cardiff Infirmary.

SIR PETER EADE, Consulting Physician to the Norfolk and Norwich Hospital, celebrated his 80th birthday on January 19th, and was presented by his colleagues on the staff of the hospital with an address, accompanied by a presentation in recognition of the high esteem in which he is held by them.

A BANQUET in support of the London School of Tropical Medicine will be held in London on May 10th. Mr. Chamberlain will preside. The Duke of Marlborough has consented to be Chairman of the Dinner Committee.

THE President of the French Republic has conferred on Dr. George Ogilvie, Senior Physician to the French Hospital, the much-coveted decoration of Chevalier de la Légion d'Honneur. Dr. Ogilvie has been on the staff of the French Hospital for some eight or nine years.

SIGNOR MANUEL GARCIA, who completes his 100th year on March 17th, will be presented by the Spanish Ambassador with his portrait, by Mr. John Sergeant, R.A., at a reception at the Hotel Cecil, and a dinner will be held the same evening at which ladies will be present.

DR. ROBERT J. ROWLETTE has been appointed Pathologist to the Rotunda Hospital, in place of Dr. W. C. Neville, deceased.

It is officially announced that Dr. L. D. Parsons, Resident Surgeon-Superintendent of the New Providence Asylum, Bahamas, is to succeed Dr. J. E. Ker as Assistant Surgeon, Colonial Hospital, Police and Port Surgeon of Gibraltar. Dr. E. Ker has proceeded to Jamaica as Superintendent Medical Officer.

MR. WILFRID ALLPORT, M.B., B.S.Lond., F.R.C.S. Edin., was last week appointed to the vacancy of Ophthalmic Surgeon at Queen's Hospital, Birmingham, to fill the vacancy caused by the resignation of Mr. Priestley Smith. Mr. Allport was a Birmingham medical student, and was formerly resident obstetric and ophthalmic surgeon at the Queen's. He was for two years at the Midland Eye Hospital in Birmingham, and for five years has acted as assistant ophthalmic surgeon to Mr. Priestley Smith.

ON the occasion of his retirement from the Glasgow Parish Council, after 20 years' service, a large gathering of friends of Dr. Wilson Bruce presented him last week with an illuminated address. Mr. Henry E. Clark, C.M.G., President of the Faculty of Physicians and Surgeons, presided over the meeting.

WE deeply regret to announce the death of Professor Ambrose Birmingham, Professor of Anatomy in the Catholic University School of Medicine. We publish elsewhere a memorial address delivered at the School by Sir Christopher Nixon, M.D.

DR. HENRY O'NEILL, a prominent member of the Belfast Municipal Council, has been nominated as High Sheriff of the city for the ensuing year. We understand that he is the first medical man to hold this post in Belfast.

Mr. E. WHITLEY, B.A., Trinity College, Oxford, has given £1,000 towards the permanent endowment of the Chair of Pathology at the University of Oxford.

SIR WILLIAM CHURCH has written to the Vice-Chancellor of Oxford, informing him that at a meeting of medical graduates in London, resolutions were unanimously passed declaring it desirable in the interests of medical education at Oxford that steps be taken to bring before the university the necessity of permanent and adequate support being received for the pathological department, and that a fund be started for the purpose of assisting.

Special Correspondence.

[FROM OUR OWN CORRESPONDENTS.]

SCOTLAND.

GLASGOW NORTH-WESTERN DIVISION OF THE BRITISH MEDICAL ASSOCIATION.—A general meeting of the above Division was held in the Burgh Hall, Byars Road, on Tuesday evening, the 24th ult. The Chairman of the Division, Mr. Thomas Richmond, presided, and explained that the Executive Committee had considered the best means to adopt by way of having a good attendance of members at the meetings. It had been arranged to issue complimentary invitations to the medical men in the Division who were not members of the B.M. Association, with the result that the attendance at Thursday's meeting was encouraging; in fact, it was what the Chairman ventured to call a record attendance over the various Divisions in the city. He went on to explain further the advantages and opportunities now given to members of the Division of having professional grievances redressed, emphasising the urgent need for hospital reform in several directions in the interest of the general practitioner, who suffered so seriously from a large class of patients being admitted into general and special hospitals who were quite able to pay doctors' fees. This was particularly noticeable, he said, in cases where an operation was requiring to be performed. He expressed his regret at the apparent indifference shown by many members with regard to matters of great importance which were brought before the Divisional meetings. The business of the evening was the discussion of the seven propositions on Contract Medical Practice contained in the Supplement to the *British Medical Journal* of November 26th, 1904. They were fully discussed by the members, and thereafter agreed to, it being generally considered that they very fairly represented all that was required.

GLASGOW SOUTHERN MEDICAL SOCIETY.—This Society held its annual supper in Ferguson and Forresters', Buchanan Street, on the evening of Thursday, the 26th ult. The President (Dr. James Hamilton) occupied the chair. The company numbered between fifty and sixty. After the loyal toasts had been proposed from the chair and duly honoured by the company, a programme of music was entered upon. Song and recitation followed in quick succession, among those contributing being Drs. J. R. Monro, Wauchope, McMillan, Smith, Patrick, and Messrs. Weir, Smith, Hope and Wilson. The evening's enjoyment was brought to a close by the late President in a few appropriate remarks proposing the health of the Chairman, Dr. Hamilton, to which he replied in a few well-chosen sentences.

APPOINTMENT FOR DR. JOHN KNIGHT, GLASGOW.—The above-named gentleman has just been appointed Medical Officer of Health for Scarborough, vacant by the resignation of Dr. Dittmar, who was recently appointed Medical Inspector for the Local Government Board of Scotland. Dr. Knight is at present assistant

to Dr. Chalmers, Medical Officer of Health for Glasgow. There were forty-three applicants for the office now secured by Dr. Knight.

BELFAST.

THE ROYAL VICTORIA HOSPITAL.—The Board of the Royal Victoria Hospital is being sharply criticised in the Belfast press for a proposal which seems to have found favour with a number of its members, and which is to come up for discussion to-day. The proposal is one to increase the salary of the Superintendent of the hospital. The gentleman who holds this post is a retired colonel of the Indian Medical Service, from which he presumably has a good pension. His salary at the Royal Victoria Hospital is £300 per annum, and he is being provided with a spacious new house in the grounds of the hospital, with free fire and light. As urgent appeals are constantly being made for funds to enable the Board to open the wards which are at present lying idle and empty for want of money, it certainly seems rather a tactless thing for this gentleman's friends to ask for an increase of salary at the present time.

THE WORKHOUSE CONSUMPTIVE SANATORIUM.—Forty patients have already been taken into the Consumptive Sanatorium at the Abbey, Whitehouse, from the consumptive wards of the Union Infirmary. As the number of phthisical patients generally runs to about 240 or so, a good deal more accommodation is needed, even to take in only the less advanced cases. This will be provided by huts built in the grounds, the present accommodation being in the house itself. An amusing instance of medical optimism occurred at a discussion on the structure of these huts, at last week's meeting of the Belfast Guardians. The point at issue was whether the huts should be built of stone or wood, and one of the members of the Board solemnly gave as a reason for the temporary form of hut the fact that one of the doctors had informed him that there would be no consumption in fifteen years' time!

THE CORONERSHIP OF THE CITY.—The death of Mr. Finnegan has created a vacancy in the office of Coroner for the City of Belfast, and naturally the appointment of his successor has much interest for medical men. The late coroner was a solicitor, who had been a prominent politician before his appointment, but it is expected that his successor will be a medical man. The favourite candidate for the post is an ex-alderman, a medical man who lately retired from the Municipal Council, and who is known to be a general favourite with the members of that body. No doubt the post will be conferred as a reward "for services rendered," and the best we can hope is that the recipient may happen by chance to be a suitable man, for suitability or otherwise will not count for much with the Municipal Council.

NEWTOWNARDS DISTRICT NURSING SOCIETY.—At the annual meeting of this society, held last week, the chair was taken by the Marchioness of Londonderry, who has before now shown a deep interest in the Society. In emphasising the great advantage derived by the poor from the nurses' visits, she remarked that the nurse was a technical educator in the matter of soap, diet, disinfection, and fresh air. She also laid stress on the point that the nurse could see that proper attention was paid to the doctor's orders.

THE LATE PROFESSOR BIRMINGHAM.

ADDRESS BY THE DEAN OF THE MEDICAL FACULTY OF THE CATHOLIC UNIVERSITY SCHOOL OF MEDICINE.

SIR CHRISTOPHER NIXON, after some introductory remarks, said:—If I might, in a brief way, analyse Birmingham's splendid abilities, I would do so under three heads—as a teacher, as an original observer, and in reference to those qualities which made his personality so attractive to all who knew him. As a teacher he was the nearest approach to the ideal that I have had experience of. With the most thorough

knowledge and grasp of his subject, he possessed the rare gift of making it transparently clear, and by a bright and vivid description invested it with such interest as to excite the rapt and sustained attention of his class. No pains were spared in presenting his subject with all the adjuncts which the most modern methods of demonstration require, and each lecture was, in the most practical way, illustrated by diagrams, models, and lantern accessories, so that an indelible impression was left on the mind of the anatomical part that was dealt with. The subject matter was presented in a way so striking and complete, so replete with illustration and so precise in form, that even to the first year's student the description of a bone was as interesting as the practical points in surface anatomy were to the most advanced student. Altogether, apart from his brilliant work as a teacher, work which, taking into consideration its constancy and laborious nature, must have kept his hands full, he found time to carry on researches with such brilliancy as to make us realise what he might have done if he had only been decreed the allotted span of human life. His three papers on the mastoid region, published in 1893, so important in their surgical aspect as to form the basis of operative procedure in this region, made the name of the young anatomist so well known that a leading aural specialist came to Dublin to examine his preparations. His work on the position of the stomach, the anatomy of the peritoneum, and of the abdominal viscera generally, is, in some respects, of an epoch-making character, whilst it exhibits a capacity for investigation which raised the author to a high level as an accurate, painstaking, and original observer. When Professor Cuninghame brought out his great work on anatomy, a work representing the collaboration of the leading anatomists of the Empire, with a generous appreciation of a rival professor's merits, he entrusted the portion of the work dealing with the anatomy of the abdomen to Birmingham, with the result that the consensus of expert opinion gave the palm of merit to Cuninghame and Birmingham for their articles. Surely this is a record which amply justifies his Eminence Cardinal Logue's generous appreciation, when he writes of Professor Birmingham—"His loss is a national loss, and at a time, too, when Catholic Ireland stands in such need of her staunchest Catholic children." The last aspect under which I may refer to Birmingham was his wonderful capacity for organisation, and his striking personality. From the time he took up the Registrarship of the School, in 1887, the institution entered upon the course of progress in every aspect and in every detail. Its finances were dealt with with the ability of a chartered accountant; each professor realised how essential it was to support in every way the man who was devoting his life largely to the vindication of a principle, and in antagonism to a bitter and relentless denial of educational rights and privileges; whilst the students felt that they were under the influence of one who exacted their respect and gained their affections. Not that Birmingham employed the customary aids, adventitious or otherwise, to gain popularity or notoriety. He was a perfectly straight man, with the highest ideals of what was due from man to man, and it was this that largely explained the singular influence which he exercised upon students. *Obsequium amicos, veritas odium parit*, however true it may be generally, could not be said to apply to him. He was the true friend of the students, never more so than when he reproved their faults, set his face against idleness or bad habits, and enforced that degree of discipline and decorum which I am glad to acknowledge is the characteristic of the modern type of students of medicine. But, if he were a disciplinarian, how just and gentle was his rule, how impartial and tolerant his methods, how earnest and thorough was his desire for your welfare, how unassuming and unvarying his relations with you all. You might say of him—

"Rich in saving common sense
And, as the greatest only are,
In his simplicity sublime."

For myself, I may say that to me the death of Birmingham has been a severe wrench. More than a moiety of a lifetime devoted to the interests of this school, I confess the loss to one of whom I was bound by all the ties which unite a favourite pupil, colleague, and friend, is a most trying one. But there is a solace which helps to dispel the gloom that affects us all. Mainly through Birmingham's work, and through the co-operation of all whom I see around me to-day, the future will not be imperilled by the loss of any individual, however great and brilliant that individual may be. No one was more sanguine as to the future before us than he who has passed away, no one more keen or anxious to secure a successor worthy of himself. I believe, gentlemen, we are on the winning side. Time in all countries and in all ages tells in favour of the demands of the governed being acceded to by those who govern, and we shall not, I hope, have long to wait for a measure of simple justice. Till that time comes we shall, I hope, continue the struggle with all the energy and dogged perseverance which has helped us to build up the largest and most prosperous Medical School in Ireland.

CENTRAL MIDWIVES' BOARD.
MEETING HELD JANUARY 26TH, 1905.

DR. CHAMPNEYS, President, in the Chair.

THE SECRETARY opened the meeting by reading memorials from the Guardians of the Bradford Union and four other Unions, asking the Board to reconsider their decision not to recognise Poor-law Training Schools as such.

Miss WILSON was of opinion that such recognition would be wise, and asked for a special meeting to consider their claims and the best method of bringing them into conformity with every requirement of the Board.

DR. PARKER YOUNG urged that each place should be examined on its own merits and no hard and fast rule made to apply to every Poor-law Institution, and it was agreed *nem. con.* that a special meeting take place.

Several cases of alleged misconduct among certified midwives were read by the Secretary, it being agreed in every case (save one of Police Court conviction) to inquire more fully into details, and no *ex parte* judgment given. In one case, where a certificate had been signed by a medical practitioner, after a midwife had had an illegitimate child, several members contended this sufficient for non-suspension, but Dr. Ward Cousins remarked that it depended on the moral thermometer of the doctor who signed.

Miss WILSON then moved that the following advertisement be issued by the Board:—"Midwives Act, 1902. The Central Midwives' Board requires the services of a registered medical woman, who has acted as house surgeon or physician in a maternity hospital or home possessing an extern department, to undertake from time to time the duties of inspector, at a fee of £1 is. with travelling expenses for each inspection. Particulars and form to be obtained from the Secretary," urging that eleven County Councils had appointed women inspectors. She would suggest that each case of inspection be paid for separately, as this would permit of securing the services of those who were specially competent but not able to give the whole of their time to the work.

DR. PARKER YOUNG wished to substitute "medical practitioner" for "medical woman." The former term would not exclude women. He imagined some men might be better than women; certainly some were as good. Wisdom was not alone in the minds of women, and medical men had had the same experience for the post of inspector.

Miss WILSON replied that the fact of eleven County Councils having appointed women proved they considered them better qualified, especially in the minor details of nursing.

The PRESIDENT inquired what there was which a man could not do, and reminded the speaker that a house surgeon and staff of a hospital maternity department had to see after midwives.

Dr. PARKER YOUNG objected strongly to the term, "medical woman," but was alone in voting against the motion, which was carried, the President not voting, nor Dr. Ward Cousins (who was called away). Miss Paget and Dr. Cullingworth voted for Miss Wilson's motion.

Printed forms of the Examination Scheme, as approved by the Privy Council, were handed round, which we hope to publish in our next issue.

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

THE GULF STREAM MYTH.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—When, in 1856, I went to Australia as Surgeon-Superintendent of a Government emigrant ship of 1,000 tons, carrying 400 souls, and such voyage lasting 100 days, my little library of science held three treasured books—Herschell's "Preliminary Discourse," "The Admiralty Guide to Scientific Inquiry," and Maury's "Physical Geography of the Sea." I well remember Maury's grand opening, "There is a river in the sea. . ."

Dr. Knott's pleasant and learned essay has not swept from my mind and fancy the old faith or myth that, from the North Cape to Cape Cornwall, the genial climate is in part due to the Gulf Stream.

The conditions involved are cosmic, co-relating with, and dependent on, the motions and energies—so-called laws—of our solar and planetary system.

The earth, revolving on its axis from W. to E., in its equatorial regions, *i.e.*, in its regions of greatest diameter, at the speed of 1,000 miles an hour, leaves its superimposed atmosphere a little behind, and thus we get the flow of wind in the tropics from the east. The cold northerly winds rush towards the region of greatest heat—from 4° to 8° N.L.; thus results the N.E. trade wind. In the Doldrums, or region of calms and greatest heat—4° to 8° N.L.—the trade winds ascend and become upper currents in an opposite direction to the trade wind. At about 30° N.L., these upper currents descend and become our westerly gales, from 30° to 60° N.L.

But observe, that when they descend they have the velocity of the equatorial and greatest diameter of the earth's most rapid rotation. The earth spins on an almost constant and perpendicular axis; thus their super-velocity makes them westerly winds, when they have descended to the higher, slower rotating, latitudes.

It is obvious that from 30° to 60° N. and S.L., the globe has a region of prevailing westerly winds.

Now, just as the tropical atmosphere is left a little in the lurch, to become an easterly wind, so must the tropical ocean lag a little behind, and thus, through the tropics, the whole body of the ocean must have a constant trend from the east to the west. See what has happened; the coast of South America, N.W. of Cape St. Roque, the great hollow of the Gulf of Mexico, the channels between the mountainous Windward Islands have been formed.

This great ocean movement, checked by the mountain ranges of Central America, sweeps round Cape Sable and Florida, and becomes the Gulf Stream.

Dr. Knott will hardly doubt but that the warm waters and atmosphere associated with the Gulf Stream are involved in the great fog region off Newfoundland. But, taking a larger view than that, if a mere "stream," what becomes of this great ocean trend—first easterly, and then, being possessed with the reliquiae of the super-rotation motions of the greater diameter of the entire tropics, finds itself cast back into higher latitudes, which have a less speed of rotation. It must have, in such more slowly revolving

latitudes, a westerly outlet. For the whole inter-tropical ocean is ever, like the trade wind, moving toward the region from St. Roque round the Gulf of Mexico to Florida.

We do not conceive of the Gulf Stream in Maury's poetic words, but that the Atlantic Ocean, from 30° to 60° S. and N.L., has ever an easterly trend, and holding the warm and diffused and super-speeded waters of the Gulf Stream, which sweeps round Florida.

Thus, in the countless ages of astronomical and geological time, have been formed the great fiords of Norway, of the West Coast of Scotland, the West Coast bays of Ireland, the promontory of Cornwall, and the English Channel itself.

I have never supposed that the Gulf Stream reached us like a visible or defined river; but I cannot doubt but that, in its origins, co-relations, and continuity, we in the South and West of Great Britain and Ireland receive the blessings of the Gulf Stream.

One may say, following the old Asiatic philosopher: "There be three things which are too wonderful for me"—(1) The ultimate, yet orderly, modes of bioplasmic reversion in chill and pyrexia; (2) the "modes of motion" imparted to bioplasm by the varied alkaloids; (3) the complex, yet orderly, motions of the winds and seas.

May Dr. Knott live long and help to show us the Keplerian laws of all these three orderly cosmic phenomena!

I am, Sir, yours truly,
WILLIAM H. PEARSE, M.D.ED.

Plymouth.

OUR ENGLISH CLIMATE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The remarks made last week by Dr. Knott on "The Gulf Stream Myths, and Seaside Resorts" were in many ways of interest to those who are anxious to have accurate information on the question of climate. It was rather amusing to read the *Daily Telegraph* on "Our English Climate" (Jan. 26th), and to look at the sunshine map, with the other alongside. Sunshine is now coming up as the prime factor in a "climate," and probably Dr. Knott's flagellation of the Gulf Stream and its mysterious character will bring effects. Of course, the worst part for the Gulf Stream is that the West coast which has been thought to have far the best of it, is very dull on the rainfall map, and with some there is no doubt, however pleasant the sun may be, rain should be avoided.

Probably Dr. Knott is right in his view that the complete disappearance of the Gulf Stream and all the ocean currents in the Atlantic would not have the slightest effect on the weather and climate of Europe. Unfortunately this article in the *Daily Telegraph* has somewhat of an advertising tone about it, and when we see further on that Weymouth is the Naples of England, and such-like panegyrics of a rather hysterical character we may feel disposed to look grave, and not inclined to listen to such treatment of the very important question of climate. If we turn from p. 6 (*D.T.*, Jan. 26th), to p. 11, and just look down at the temperature in Brighton (47°), or Hastings (49°F.), and compare these with Biarritz (59°), or Cannes (61°F.), we can see what is gained by going south in the winter. Those who have travelled much and studied climate carefully are not disposed to regard our climate as a good one. The simple fact of pulmonary diseases being prevalent ought not to be lost sight of, and now that many are migrating to one of our Colonies, very accurate and reliable information should be given in our public papers, so that none may be misled.

I am, Sir, yours truly,

R. L.

London, January 30th, 1905.

STERILISATION OF CERTAIN DEGENERATES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Dr. Rentoul is mistaken if he supposes that a "student of sociology" is necessarily a juvenile. My years, I am afraid, are not less numerous than his.

and I have been a student all my life since my juvenile days. I, and many of us, want to know how Dr. Rentoul proposes in the present state of the law to set about the sterilisation of the vast crowd of degenerates he enumerates and describes, and whose existence we all deplore. Will any proportion of them consent to undergo the operation? Does he propose to lay hands upon them forcibly, to sterilise them, and forcibly detain them until the operation wounds are healed? To do this would be a criminal offence, and in the event of a death from virulent inflammation following the operation, would involve a charge of manslaughter, if not of murder. Moreover, every surviving victim would easily find an enterprising solicitor willing to conduct with the certainty of success an action for damages against the operator. To discuss the law as it applies to surgeons performing operations with or without the consent of patients, under ordinary circumstances, or destroying a foetus to save the life of a mother is not closely to the point, interesting as that subject may be. Sterilisation of degenerates cannot be carried out without special new legislation, and no one with any knowledge of the subject, except perhaps Dr. Rentoul, can suppose that any Government, much less any private member of Parliament, would expose themselves to the ridicule with which such a project of law would surely be received. It seems a pity such a waste of good force on Dr. Rentoul's part should go on, and my object in writing was to try to stop it. Dr. Rentoul says he is a general practitioner, not a specialist. May one without offence suggest for his consideration the ancient maxim—*Ne sutor ultra crepidam?*

I am, Sir, yours truly,

A STUDENT OF SOCIOLOGY.

January 26th, 1905.

Obituary.

DANIEL GIBSON PEARCE THOMSON,
M.D. EDIN.

WE regret to record the death of Dr. Thomson, of Penrith, Cumberland, at the early age of 44 years. He was born at Leith in 1860, and was educated at the University of Edinburgh, where he graduated M.B. and C.M. in 1883, and M.D. in 1897. In 1887 he became assistant to the late Dr. Robertson, of Penrith, and entered into partnership with that gentleman in 1889. Dr. Thomson carried on an extensive general practice with marked ability and success. His early death is a great loss to his widow and six children, and a large circle of patients and friends.

JAMES MUNRO, M.D. ED., J.P., OF BARNARD
CASTLE.

DR. MUNRO, M.D., J.P., was a distinguished student of Edinburgh University, where he graduated in 1859. He was Surgeon-Lieutenant-Colonel to the Durham Militia, Chairman of the Barnard Castle Division of the North Riding and Durham County Bench, and an active supporter of the Conservative party in his own town; the latter frequently entailed lengthy speeches. In later years he conducted a large county practice. His sudden death, from paralysis, is a loss not only to patients, but to medical literature, and to the social and political life of his district.

HENRY WILSON, M.D. ST. AND., M.R.C.S. ENG.,
OF LIVERPOOL.

WE regret to announce the death of Dr. Henry Wilson, which took place quite suddenly, of heart failure, at his residence, Wavertree, Liverpool. He was in his 65th year, and received his medical education at Anderson's College, Glasgow, and qualified M.R.C.S. Eng. in 1863, and L.S.A. the following year. He became M.D. St. And. in 1890. He first started practice in London, whence he removed to Marske-by-the-Sea, where he was appointed Medical Officer to the Earl of Zetland's Ironworks.

THOMAS PERCIVAL, M.R.C.S. ENG., L.S.A., OF
KNOTTINGLEY.

THE death of Mr. Thomas Percival, M.R.C.S., of Knottingley, Yorks., occurred after a few days' illness. He received his medical education at the Leeds School, and obtained the diploma of M.R.C.S. in 1866, and that of L.S.A. in 1867. He carried on an extensive private practice in Knottingley, and held many appointments. He was one of the Vice-Presidents of the Yorkshire Branch of the Incorporated Society of Medical Officers of Health. He has left a widow and five children with whom much sympathy is felt.

Medical News.

Outbreak of Diphtheria.

A SERIOUS outbreak of diphtheria has occurred at Pointon, near Billingham. Several cases have been reported, and two deaths have already taken place. Some grown-up people are amongst those suffering from the complaint. The village had only just recovered from an epidemic of scarlet fever when the first case of diphtheria was notified. The sanitary officials have this week inspected the condition of the parish drain, which in part flows as an open water-course alongside the village street. This is said to be polluted with sewage matter, and is believed to have had something to do with the outbreak.

Influenza Epidemic in North Wales.

SOUTH Carnarvonshire is in the grip of a severe epidemic of influenza. Over fifty people are being medically treated in the Pwllheli district, and hundreds are down in Portmadoc and Crickieth. Several schools have been closed. The schools at Pentre, Brynteg, Brymbo Vron, Gweryllt, and Cross Street, in the Wrexham district, have been closed on account of an epidemic of influenza.

The Royal College of Surgeons.

The ceremony of conferring the Honorary Fellowship of the Royal College of Surgeons in Ireland on Dr. Traill, Provost of Trinity College, will take place in the College, Stephen's Green, on the evening of Saturday, February 11th, at 7 o'clock, in the presence of his Excellency the Lord Lieutenant. Subsequently the Earl of Dudley and the Provost will be entertained at dinner by the President and Fellows of the College.

International Anti-Alcohol Congress.

THE tenth International Anti-alcohol Congress will be held at Bucharest this year from September 12th to 17th. Among the questions proposed for discussion are the Sunday closing of public-houses and drinking saloons.

Conjoint Examinations in Ireland.

CANDIDATES have passed the supplemental Final Examination as undernoted—(Winter Session, 1905):—Francis Lyndon Bradish, Eugene Aaron Bernard, Charles Paget O'Brien Butler, Frederick James Cairns, Douglas Edward Crosbie, James Stuart Dunne, Jennette Carroll Hargrave, Patrick Mary Moore, Reginald Anthony Murphy, Donald De Courcy O'Grady, Martin O'Keefe, William Sheehen.

THE Royal Dental Hospital, Leicester Square, has received a donation of £100 from the Worshipful Company of Goldsmiths.

THE annual meeting of the German Association for Scientists and Medical Practitioners is to be held this year at Meran from September 24th to 30th.

THE foundation-stone has been laid of a convalescent home for aged Frenchmen at Brighton. The home will be carried on in connection with the French Hospital in London.

THE second French Congress of Climatotherapy and City Hygiene will be held at Arcachon on the 24th to 29th of April next. The President is Professor Renant, of Lyons. The work of the Association is divided into various sections. Those interested in the subject can obtain any desired information of the General Secretary, M. C. D. Festal, Villa David, Arcachon.

Notices to Correspondents, Short Letters, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive Signature or Initial*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

ORIGINAL ARTICLES or **LETTERS** intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in re-forwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

THE CIRCULAR PRESCRIPTION.

A consultant physician writes to tell us of a postal packet sent to him by the Dead Letter Office. It contained a letter of thanks from a young lady to a former patient thanking him for the use of his prescription, and saying she had carefully followed all directions. The prescription was much battered and creased and countersigned by chemists, evidently in the result of many previous journeys of a similar kind. The patient in this case was a barrister. From a gentleman named as an intellectual profession one might have looked for better things. Obviously to use one prescription for many patients is to court disaster. Our correspondent says his first impulse was to send the whole packet off at once to his former legal patient—but on second thoughts he relegated it to the waste paper basket. The incident illustrates the fetish worship of prescriptions often evinced even by so-called educated people.

W. E. F.—The gentlemen you addressed is out of town for several weeks, but your letter will be given him on his return. We hope to hear from you often in your new capacity.

MEDICAL EDITORS IN GLASS HOUSES.

Sir.—In your "note" in yesterday's issue under the above heading (p. 94) occurs the following, "It is not easy to see on what grounds a medical Editor can cry 'Maranatha' to a medical man," etc. This, I presume is a mistake for "Anathema," *accused* (a not uninfrequent mistake), whereas "Maranatha" means "Our Lord cometh." The E.V. rightly separating the two words by a full stop.

Yours faithfully, H.S.
[We thank our correspondent for calling attention to an obvious slip.—Ed.]

Meetings of the Societies, Lectures, &c.

WEDNESDAY, FEBRUARY 1st.

OBSTETRICAL SOCIETY OF LONDON (20 Hanover Square, W.).—8 p.m. Annual Meeting. Specimens will be shown by Mr. Targett, Mr. Handley, Dr. F. E. Taylor, and Mr. Bland Sutton. Short Communications.—Dr. E. W. H. Groves: A New Operation for the Cure of Vaginal Cystocele. The President (Dr. Mallins): Annual Address.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chancery Street, W.C.).—4 p.m. Mr. P. G. Freyer: Clinique. (Surgical.) 5.15 p.m. Mr. A. W. M. Robson: Pancreatic Cysts and Pancreo-lithic Calculi.

CENTRAL LONDON THROAT AND EAR HOSPITAL (Gray's Inn Road, W.C.).—5 p.m. Demonstration.—Mr. S. Low: Oral and Laryngopharynx.

THURSDAY, FEBRUARY 2nd.

ROENTGEN SOCIETY (20 Hanover Square, W.).—8.15 p.m.—Messrs. Newton and Son will show Dr. T. Holland's X-Ray Diaphragm Compressor. Paper.—Dr. C. A. Wright: Some Points in the Construction of a High Frequency Machine (accompanied probably by some novel exhibits).

NORTH-EAST LONDON CLINICAL SOCIETY (Tottenham Hospital, N.).—4 p.m.—Clinical Cases.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chancery Street, W.C.).—4 p.m. Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m. Dr. T. W. Eden: Acte's Torsion of the Pedicle in Pelvic Tumours.

MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (7 Fitzroy Square, W.).—5 p.m. Lecture: Dr. J. E. Squire: "Murmurs" not dependent on Diseases of the Heart. (Post-Graduate Course.)

FRIDAY, FEBRUARY 3rd.

SOCIETY OF ANÆSTHETISTS (20 Hanover Square, W.).—8.30 p.m. Exhibition of Ethyl Chloride Inhalers before and after the meeting. Papers: Mr. Wade: On the Presence of Ethyl Chloride in Commercial Chloroform.—Mr. B. Hird: Ethyl Chloride in Eye Practice, with an account of a Fatality.—Dr. Barton: Continuous Administration of Ethyl Chloride in operations about the Upper Air Passages (followed by discussion to be opened by Dr. McCardie).

WEST KENT MEDICO-CHIRURGICAL SOCIETY (Royal Kent Dispensary, Greenich Road, S.E.).—8.30 p.m. Paper:—Dr. Annis: Immunity against Disease.

LARYNGOLOGICAL SOCIETY OF LONDON (20 Hanover Square, W.).—5 p.m. Cases and Specimens will be shown by Mr. O. A. Parker, Dr. F. Spicer, Mr. P. de Santi, and others.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chancery Street, W.C.).—4 p.m. Mr. R. Lake: Clinique. (Ear.)

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen Square, Bloomsbury, W.C.).—3.30 p.m. Dr. Batten: Nerve Terminations in Muscle.

TUESDAY, FEBRUARY 7th.

NORTH-EAST LONDON CLINICAL SOCIETY (Tottenham Hospital, N.).—4 p.m. Dr. Chappel: Clinical Medicine.

Bacancies.

Monmouthshire Asylum, Abergavenny.—Junior Assistant Medical Officer. Salary £150 per annum, with board, lodging and washing. Applications to the Medical Superintendent.

Craig-Leith Poorhouse and Hospital, Edinburgh.—Medical Officer. Salary £100 per annum, with board, and apartments. Applications to And. Ferrier, Clerk, Parish Council Chambers, Castle Terrace, Edinburgh.

Brompton Hospital for Consumption and Diseases of the Chest.—Assistant Resident Medical Officer. Salary £100 per annum, with board and residence. Applications to the Secretary.

East London Hospital for Children, and Dispensary for Women, Shadwell, E.—Pathologist and Registrar. Salary £100 per annum. Applications to Thomas Hayes, Secretary.

South Devon and East Cornwall Hospital, Plymouth.—House Surgeon. Salary £100 per annum, with board, residence, and washing. Applications to P. J. Langdon, Secretary.

Leeds General Infirmary.—Resident Medical Officer. Salary £100 per annum, with board, residence, and washing. Applications to the Secretary.

Bolton Infirmary and Dispensary.—Junior House Surgeon. Salary £100 per annum, with furnished apartments, board and attendance. Applications to the Hon. Secretary, W. W. Cason, Esq., 20 Mawdale Street, Bolton.

Manchester Children's Hospital, Pendlebury.—Lady Superintendent. Salary £100 per annum, with board, rooms, washing, and attendance. Applications to the Secretary at the Hospital, Pendlebury.

Lewisham Union.—Medical Officer. Salary £180 per annum. Applications to H. C. Mott, Clerk to the Guardians, Union Offices, 286 High Street, Lewisham, S.E.

Sunderland Infirmary.—House Physician, House Surgeon, Assistant House Surgeon. Salary £100 per annum, with board, residence and washing. Applications to the Secretary.

Rochdale Infirmary.—Resident Medical Officer. Salary £100 per annum, with board, residence, and washing. Applications to Henry Booth, Secretary, 58A York Street, Rochdale.

Somerset and Bath Lunatic Asylum, Wells Somerset.—Medical Superintendent. Salary £100 per annum, with furnished house and allowances. Applications to John Coates, Clerk to the Visiting Committee.

Egyptian Government—Ministry of Public Instruction.—Professor of Pathology and Bacteriology at the School of Medicine, Cairo. Salary £800 per annum. Applications to the Director, Government School of Medicine, Cairo, Egypt.

Township of Manchester.—Assistant Medical Officer. Salary £110 per annum, with furnished apartments, fire, light, and attendance. Applications immediately to James Macdonald, Clerk to the Guardians, Poor-law Offices, New Bridge, Manchester.

North of Ireland.—B. C. Doctor for a good practice. D., Dublin Office of this paper. (See Advt.)

Hydropathic Establishment.—Resident Physician. Applications to J. Adams and Son, 17 Merrion Row, Dublin. (See Advt.)

Navy Medical Department.—Three Dental Surgeons for Portsmouth, Plymouth and Chatham. Salary £1 per diem and traveling expenses when necessary. Applications to the Director General, Medical Department of the Navy, 18 Victoria Street, S.W. (See Advt.)

Appointments.

AMNOT, THOMAS ENGELHART, M.B., B.S., Durh. House Surgeon to the Dorset County Hospital, Dorchester.

ATKINSON, J. P., M.R.C.S., L.R.C.P.Lond. Certifying Surgeon under the Factory and Workshop Act for the Lynton District of the county of Devon.

BENNETT THOMAS M.B., Ch.B., Glasg. House Physician to the Derbyshire Royal Infirmary.

Marriages.

LIAS—CARVER.—On Jan. 27th, at St. James's, Piccadilly, Francis James Lias, of Yokohama, Japan, to Marian Elizabeth, only surviving daughter of the late Edmund Carver, Esq., M.D., of Cambridge, and of Mrs. Carver, "Barramotee," Torquay.

Deaths.

DOBIE.—On Jan. 27th, at 63 Woodbury Park Road, Tunbridge Wells, Edward John Dobie, Captain, R.A.M.C., aged 33 years.

FRANCIS.—On Jan. 29th, at Allstrass, St. Julian's Farm Road, West Norwood, Melina Anna, widow of the late Surgeon-General Charles Richard Francis, M.B. of H.M. Indian Army, aged 76.

SUTTON.—On Jan. 30th, at Dharmasala, Punjab, suddenly, Margaret the beloved wife of S. W. Sutton, M.D., Medical Mission, C.M.S.

The Medical Press and Circular.

UTERINE DISPLACEMENTS. (a)

By ARTHUR E. GILES, M.D., B.Sc.Lond.,
F.R.C.S.Ed.,

Gynaecologist to the Tottenham Hospital; Assistant Surgeon,
Chelsea Hospital for Women.

GENTLEMEN,—I shall confine my present remarks to the consideration of certain points in the symptoms, diagnosis, and treatment of two forms of displacement—namely, Retroversion and Prolapse.

RETROVERSION.

With this I shall include retroflexion, because the two conditions are very frequently associated. Without entering into the question of the causation, I may say that, broadly speaking, retroversion depends on conditions outside the uterus, and especially relaxation of ligaments; whilst retroflexion is rather due to conditions inherent in the uterus, and perhaps mainly to want of tonicity in its musculature.

Symptoms.—Some doubt has been expressed as to the possibility of symptoms being produced by retroversion pure and simple, by which I mean a retroversion that is not complicated by endometritis, hyperplasia of the uterus, or prolapse or inflammation of the ovaries and tubes. Experience leads me to hold the view that an uncomplicated retroversion is capable of producing symptoms, and does so in a minority of cases. At the same time I readily concede that in most of the cases in which symptoms arise they are due to some associated condition. I have met several cases in which a retroversion caused reflex disturbances, such as nausea and vomiting; and the relationship was demonstrated by the immediate improvement which followed replacement of the uterus, and by a return of the symptoms when the retroversion recurred. In other cases an uncomplicated retroversion has just as constantly been accompanied by distressing backache, which reposition of the uterus relieved.

In most cases in which a retroversion has existed for a little time, a degree of hyperplasia supervenes, due to the chronic congestion to which the displaced organ is subjected; and endometritis with erosion of the cervix may be added. Backache then becomes a constant symptom, accompanied by a feeling of weight in the pelvis, causing lassitude. A more or less profuse leucorrhœa adds to the patient's discomfort. The symptoms are liable to be accentuated at the menstrual periods, and the quantity of blood lost becomes increased, till it merits the term menorrhagia. Then another factor is introduced—namely, prolapse of the ovaries and tubes; they share in the congestion, become swollen and tender, and the patient complains of pain on intercourse, and aching pains referred to the iliac regions. The sequence of events that I have just given in outline is a frequent one; but in some cases endometritis is an initial condition, and the displacement is secondary. The general health usually becomes

affected after a time; the feeling of lassitude and the readiness with which the patient becomes tired lead to an indoor, invalid life; the tendency to constipation, from which so many women suffer, becomes increased, and in a vicious circle adds to the already present congestion of the pelvic organs. Hæmorrhoids form a not uncommon complication; they are due partly to constipation and partly to direct pressure of the bulky uterus on the rectum. Here, then, we have a picture which, because it is so common, we may regard as drawn from life.

Diagnosis.—In most cases the diagnosis of a retroversion is one of the easiest things in gynaecology; yet there are some pitfalls which lead to mistakes being made in a rather surprisingly large proportion of cases. In the first place mistakes arise because a retroversion is diagnosed from the position of the cervix, instead of from the position of the fundus. It is true that we usually find that when the fundus is retroverted the cervix points forwards, lying in the axis of the vagina instead of being at right angles to it (Fig. I). But in a case of acute anteversion, the cervix may lie pointing forward and yet the fundus may be lying quite forward also (Fig. II). On the contrary, a cervix pointing backwards is usually associated with a fundus in the normal position (Fig. III); but in a case of acute retroflexion the fundus may be lying in the pouch of Douglas, whilst the position of the cervix is not appreciably affected (Fig. IV). Then, again, an erosion limited to the posterior lip of the cervix is rather characteristic of a backward displacement of the uterus; and one on the anterior lip alone is usually associated with normal anteversion; but if we attempt to diagnose the position of the uterus by looking through a speculum we shall fall into errors such as I pointed out when speaking of the position of the cervix. The third fallacy is due to the assumption that a rounded swelling felt behind the cervix, in the pouch of Douglas, is necessarily the body of the uterus. It is so, in most cases; but on the other hand we may have to do with a small tumour, ovarian or fibroid, lying behind the uterus (Fig. V); or the swelling may be due to a collection of fluid, to a tubal pregnancy, or to prolapsed and inflamed appendages.

Lastly, we must not assume that there is a backward displacement because we do not feel the body of the uterus lying behind the pubes. It is to be remembered that the normal uterus is a very mobile organ, possessing a considerable normal range of movement in an antero-posterior plane; and sometimes the fundus is found neither quite forward nor quite back, but in an intermediate position, with its long axis parallel with the long axis of the body (Fig. VI). This is called "Retroposition."

The moral of all this is that in making a diagnosis of retroversion we must not be guided by the position of the cervix alone; nor must we draw hasty conclusions from any solid body felt behind the cervix; nor from the absence of a solid body behind the pubes. We must be guided by the bimanual examination, in order to determine *where* the fundus actually is; and when we call something behind the cervix the fundus, we must be quite sure that the fundus is not actually elsewhere.

(a) An Address delivered at the North-East London Post-graduate College, Tottenham.

The cases that present the greatest difficulty in diagnosis are those in which two or more swellings are found, one of which occupies the pouch of Douglas. All we can be sure of, on digital examination, is that one of the these swellings is the uterus. Here we receive the greatest possible assistance from the use of the sound. If the point of the sound passes forwards, leaving the swelling in the pouch of Douglas untouched, it is evident that the latter is a tumour or one of the swellings previously mentioned; on the other hand, if the point of the sound passes backwards into the swelling, this must be the fundus, and the swelling felt in front is the non-uterine one. There is only one condition in which the following out of the rule here given may still lead to a mistake, and that is such a rare condition that it hardly counts. I refer to a case of double uterus, of the type of uterus didelphys, in which one

FIG. I. a Normal axis of the uterus. b Axis of the vagina.

FIG. II.

half of the uterus might be lying back, whilst the other half pointed forwards. Perhaps the greatest difficulty of all is found in a case where there is reason to suspect early pregnancy, and the passage of the sound is consequently contra-indicated. We may then have to wait for the assistance of time in making a diagnosis.

I shall defer what I have to say about treatment, so as to consider the treatment of both forms of displacement together. I therefore pass on to the second form of displacement.

FIG. III.

FIG. IV.

PROLAPSE.

With this condition I shall include procidentia, inasmuch as the latter may be regarded as a later and more pronounced stage of prolapse. With procidentia it is not merely a question of the uterus coming lower down so as to protrude from the vulva; there is also in nearly every case a varying degree of hyperplasia, affecting especially the supravaginal portion of the cervix. This has an important bearing on the question of treatment, as we shall see later on.

Symptoms.—In the early stages of prolapse the symptoms are almost identical with those of retroversion. As a matter of fact, there is nearly always some degree of retroversion to start with. And so we find the patient complaining of backache, pain in the lower abdomen, a feeling of weight and dragging in the pelvis, with the accompanying lassitude and lack of energy. When the uterus is lying in the lower part of the vagina with the cervix almost if not quite presenting at the vulva, there is a "bearing-down" feeling, a sensation of a foreign body to be expelled from the vagina. This degree of prolapse is frequently accompanied by some bulging of the vaginal walls, especially the anterior; and this gives rise to frequency of micturi-

tion, owing to bladder irritation. The next stage is that in which a considerable portion of the uterus and the vaginal walls is forced outside the vulva when the patient is straining or even standing; as the vaginal orifice becomes more and more stretched, the hernia becomes more and more constant, until the patient may have considerable difficulty in returning the uterus. It is a remarkable fact that patients generally appear to suffer less discomfort when the uterus is completely outside the vulva than when it is lying low in the vagina; I suppose that the sense of something to be expelled is what gives the most discomfort. Whatever the explanation may be, it is certain that we not infrequently find women who have gone about with apparent nonchalance for months or years with the uterus and vagina outside the body; and doubtless some who come for advice would have done without

FIG. V.

FIG. VI.

even longer, were it not that a new symptom is apt to come on, namely, bleeding. This results from ulceration of the everted vaginal walls, due to friction against the clothes; with the bleeding there may be some discharge from the raw surfaces; and alarm at the occurrence of bleeding or repugnance for the soiling of the clothes with discharge will lead the patient to seek advice, though the presence of a large hernial mass between the legs was apparently a matter of indifference.

Diagnosis.—Nothing could be simpler than the diagnosis of prolapse and procidentia. The uterus is

FIG. VII.

a Hyperplasia of the supravaginal portion. b Prolapse. c Hyperplasia of the vaginal portion. B Bladder. R Rectum.

found low down in the vagina, or lying outside, as the case may be. In the recumbent posture, however, a prolapse may not be evident unless the patient be caused to strain, or "bear down" as the midwives phrase has it. Of course, the prolapse will also be manifest if the patient be examined standing up; but it must be remembered that if a woman be caused to strain in the erect posture a certain amount of prolapse might be diagnosed in the healthiest woman. By adopting this procedure a certain notorious woman quack made much wealth in Manchester in my student days. She first gave free lectures to "women only," when she took the opportunity of inviting her audience to visit her at her rooms. As a result, an incredibly large proportion of healthy women were found to have prolapse, for which the lady-professor had an unfailling remedy in the form of a special pessary, which was charged for in a ratio suited to the gullibility of the patients.

Although the diagnosis of prolapse is so easy, there are nevertheless several important points to be borne in mind. The first is that behind the prolapse, and causing it, there may be some pelvic tumour; this will readily be discovered on reducing the prolapse, when the pelvis will be found to be unduly occupied. In the second place, prolapse of the uterus must be distinguished from hyperplasia of the cervix, of which it will be remembered that there are two forms, according as the hyperplasia affects the vaginal or the supravaginal portion of the cervix. The difference between prolapse and the two forms of hyperplasia is that in the former the fundus lies low down in the vagina, whilst in hyperplasia the fundus will be found in its normal position, and the uterine cavity will be found considerably lengthened. Another point of difference between prolapse and hyperplasia of the vaginal portion is that in the latter case the vagina is of normal length, though the cervix may be presenting at the vulva. This distinction does not hold in the case of hyperplasia of the supravaginal portion, because there the vaginal vault is carried down with the cervix, just as it is in prolapse. A glance at Fig. VII will show the relation of the parts in these three conditions.

Some other conditions might conceivably be mistaken for prolapse, namely, inversion of the uterus and a fibroid extruded from the cervical canal; but there would be but little ground for such a mistake, inasmuch as the part that presents in prolapse is the cervix; whilst in the other cases it would be a rounded body in which no aperture corresponding to the external os would be found.

Treatment.—In considering a retroversion there are three courses open to us. We may leave it alone, we may support the uterus with a pessary, or we may fix it in position by operation. Each course is the proper one under certain conditions, and we have now to consider what those conditions are.

A Retroversion should be left alone in nearly every case in which it causes no symptoms; and especially when the patient is unmarried, or is approaching the menopause.

A Retroversion should be treated by means of a pessary in some cases in which it causes no symptoms—namely, in married women, where the displacement is unfavourable to conception. In uncomplicated cases in which the displacement, although causing symptoms, may be regarded as a temporary phase, a pessary is proper treatment; for instance, in young married women who may be expected to conceive, and in women who have recently been confined. When retroversion is complicated by hyperplasia the best plan is to first employ depletory treatment by means of hot douches and glycerine tampons, and then adapt a pessary. When endometritis is present, treatment by means of a pessary should be preceded by curetting. Whenever the uterus is freely movable, and there is no disease of the appendages, a pessary should be tried as the first step in treatment, that is, before contemplating any operation for its fixation.

A word or two as to pessaries. It must be remembered that it is absolutely useless to insert a pessary unless the uterus can first be brought into proper position. Speaking generally, a ring pessary is of very little use for retroversion; some modification of the Hodge pessary should be used. The kind that I have found give the best results is the Braxton Hicks type, with a thick posterior bar.

The effective scope of pessaries is distinctly limited, because they are positively contra-indicated in cases in which there is a uterine tumour or any inflammatory disease of the vagina, uterus or appendages, and in my opinion they are also contra-indicated in cases in which there is good reason to believe, or experience of them for some time has shown, that the retroversion cannot be cured by this means and that the patient will have to continue wearing the pessary for an indefinite number of years.

A Retroversion should be treated surgically whenever it is complicated by adhesions fixing it in a faulty position, and in all cases in which the retroversion is a minor

feature of the case, for example, when there are uterine fibroids, ovarian tumours, or diseased appendages. Cases of old standing, complicated by hyperplasia and endometritis, should be first curetted and then treated radically by ventro-fixation. When pessaries have been tried for some time and there appears to be no prospect of the uterus retaining its position unaided, surgical measures should be adopted. In the future, we shall probably regard the practice of compelling a patient to wear a pessary for eight or ten years or more, with the necessity thereby entailed of frequent manipulations and examinations, as a relic of barbarism, and, indeed, some of us are inclined to take this view even now. And this is especially the case in those not infrequent instances in which, although a pessary is worn, it fails to keep the uterus in its proper position, and the state of the patient may be described as one of modified discomfort.

I may say a few words about the different surgical procedures that have been recommended and adopted for the cure of retroversion. The first was Alexander's operation for the shortening of the round ligaments, an ingenious procedure which apparently has given good results in its originator's hands, and in the practice of some others. It has been but little heard of for some years, having been superseded by other operations. Probably the reasons for its not taking a permanent place in the treatment of displacements were, first, the fact that the round ligaments were not always well enough developed to be of service, and were not always easily found; secondly, the fact that it was not possible to examine at the same time the conditions of the appendages, or to free adhesions if present; thirdly, some uncertainty of results. The next step was the opening of the abdomen, and the suspension of the uterus by sutures to the peritoneum or the abdominal wall; but while this allowed of free examination of the pelvic organs, and retained a considerable degree of mobility of the uterus, it had the drawback that the peritoneum was not resistant enough to hold the uterus up, and the displacement nearly always returned. Then some operators, apparently determined that the uterus should at any rate remain fixed to the abdominal wall in a position of marked anteversion, sutured it to the fascial and muscular layer of the abdomen by numerous sutures passed through the fundus and posterior surface of the uterus. The results were excellent, in that there was no return of retroversion; but if any patient subsequently became pregnant, disaster followed in the form either of early abortion or of serious and sometimes even fatal complications at the time of delivery. Dührssen then proposed vagino-fixation, of which various minor modifications were introduced by other surgeons; the results were not very satisfactory as regards the return of displacement, and numerous cases were recorded in which complications occurred during pregnancy and labour. The operation never came much into favour in England, and it is not often heard of now. Meanwhile, there were some who felt that some form of abdominal hysteropexy would prove to be the best plan after all; if, they said, the fixation were more secure than it is in ventro-suspension, and yet not so rigid as in the plan of fastening up the uterus by its posterior surface, a happy mean might be hit upon. And so they passed the sutures low down on the anterior surface of the uterus, and carried them through the peritoneum and fascia of the abdominal wall. This is the plan which I have practised now for several years, and the results have been highly satisfactory; as far as I know, there have been only two cases in which the retroversion has returned, out of over eighty cases of ventro-fixation. You will ask, however, what happens when patients become pregnant? Well, by the plan adopted, the fundus of the uterus, which is the part chiefly involved in the enlargement of pregnancy, is left free to expand as it will. Some six of my cases have become pregnant after ventro-fixation, and there has not been any complication during labour. One of them miscarried, but she became pregnant too soon in my opinion—namely, within a few weeks after operation; and this

is one of the two cases in which the displacement recurred.

I have by no means enumerated all the operations devised for retroversion. I may incidentally mention the plan of the vaginal shortening of the round ligaments; that of a modified Alexander's operation, in which the inguinal openings are enlarged to allow of a digital examination of the ovaries and tubes; and that of the intra-abdominal shortening of the round ligaments, of which again there are several modifications. In my opinion, ventro-fixation is the best surgical procedure for the treatment of retroversion.

It only remains now for me to speak of the treatment of prolapse. This differs from retroversion in that while some cases of the latter displacement can quite well be left alone, every case of prolapse requires treatment. The simplest plan is by means of pessaries; and here the rubber ring pessary is usually the best. In a certain proportion of cases a cure may be effected, because when the uterus has been kept in position for some time, its ligaments may regain some of their tone, and it will then remain in proper position without a pessary. This is especially the case when the patient is approaching the climacteric; for then the process is aided by the natural contraction of the vagina and atrophy of the uterus incidental to the menopause. But if there seems a prospect that pessaries will have to be worn for many years, surgical treatment is indicated; and this will nearly always be the case when the perinæum has been torn, or the vulvar orifice greatly stretched. Indeed, this factor may play such an important part that a ring cannot be worn at all, because the vaginal orifice gapes so much that a pessary cannot be retained. Obviously the proper treatment in such a case is to narrow the vaginal outlet by means of the operation of perineorrhaphy. This will at least permit of a pessary being retained, if so desired. But patients sometimes ask whether, if they are to have an operation, they cannot have something done to cure the prolapse altogether, and save them the perpetual annoyance of pessary treatment. Fortunately, the answer is in the affirmative; at the same time that the perineorrhaphy is done, the uterus can be attached to the anterior abdominal wall by ventro-fixation; and there are few operations of election that give more satisfactory and even brilliant results. Sometimes a ventro-fixation alone is done; but in many cases the results of this are disappointing if the perinæum is deficient; and I have long since come to the conclusion that if a prolapse is treated surgically, the two procedures, ventro-fixation and perineorrhaphy, should be done at one sitting. There is one important point to be taken into consideration when such a step is contemplated—namely, the hyperplasia which nearly always accompanies prolapse. I said, when first speaking of prolapse, that this hyperplasia had an important bearing upon treatment. If a prolapsed and hyperplastic uterus be treated by ventro-fixation, the cervix will probably still be so low in the vagina as to cause considerable discomfort, and give the patient the idea that the operation has been a failure. So the proper procedure in these circumstances is to first reduce the hyperplasia by keeping the patient in bed for one or two weeks if possible, and by carrying out depletory treatment by means of glycerine tampons and hot douches. This will often reduce the length of the uterus by an inch or more. If the uterus fails to respond sufficiently to this treatment, or if circumstances will not allow of its being carried out, then the best plan is to dilate and curette the uterus, amputate a portion of the cervix, repair the perinæum, and then open the abdomen and secure the fundus to the abdominal wall. This should be done at one sitting, in the order given. In conclusion, let me say that in the surgical treatment of displacements, whether retroversion or prolapse, we must not hesitate to combine several procedures in one operation. We must consider the various factors concerned, not only the displacement, but also the endometritis, the deficient pelvic floor, and the elongation of the cervix, if one or more of these complications be present. Curetting,

perineorrhaphy and ventro-fixation can all be done in one case in half an hour if we do not spend the time in gossip or in "playing about." This principle of thoroughness will enable us to cure our patients, the adoption of more casual methods will result in a proportion of failures.

LATERAL CURVATURE OF THE SPINE:

THE IMPORTANCE OF EARLY RECOGNITION WITH A VIEW TO SUCCESSFUL TREATMENT. (a)

By SIR LAMBERT H. ORMSBY, M.D., F.R.C.S.,
Ex-President, Royal College of Surgeons, Ireland; Senior Surgeon
Meath Hospital and County Dublin Infirmary.

THE importance of early recognition of spinal curvature is seldom realised, although at the initial stage almost all cases can be successfully treated.

Those who devote special attention to this branch of surgery are aware of the ignorance that exists regarding it. Schoolgirls, at the plastic ages, between ten and fifteen, are allowed to assume all kinds of awkward attitudes while sitting at desk and table, piano and typewriter,

FIG. I.

and when in bed to contort their bodies into abnormal shapes, yet it is well known that long-continued posture in one position is certain sooner or later to induce trouble, if not permanent deformity.

Mothers, governesses, nurses, who have special charge of young boys and girls, should examine the children periodically, stripping them to their hips and putting them through a careful and minute inspection, so as to assure themselves that no deviation of the spine from the normal condition is present. Having paid considerable attention to this subject and examined many hundreds of cases, I invariably have to say to the parents, when seeing such a case for the first time—"When did you first notice this curvature? It is a very great pity that you allowed it to run

(a) Being the substance of a Clinical Lecture delivered at the Meath Hospital and County Dublin Hospital.

on so long, as the longer it has existed the greater will be the harm done, and the more tedious and more difficult the treatment."

Another difficulty to be contended with is the reluctance of parents to understand that treatment, to be successful, must be carried out in a hospital, under the surgeon's own personal supervision and daily observation. With regard to the time necessary for the successful treatment and cure of any case, it is simply impossible to fix any date.

Many friends of patients, either from want of means or disinclination to part with their children for a term, have recourse to the instrument-makers, who will furnish a special mechanical support, which encourages vain hopes that it is effecting a cure, whereas it is only covering up and hiding the mischief.

Many a fine handsome young girl is allowed to grow up with an ever-increasing deformity,

FIG. II.

her friends not noticing anything wrong till, perhaps, the dressmaker, fitting a frock, accidentally discovers that the two sides of the back do not correspond. This perhaps is the first time anything wrong has been discovered, although the curvature must have existed for many months, and then the surgeon's aid is sought at a time when the treatment will be necessarily tedious, whereas were it discovered six months earlier it would most likely have been short and certainly far less complicated.

In early cases of lateral curvature, before any osseous rotation has taken place in the bodies of the vertebrae, and when the curvature is merely due to muscular contraction with ligamentous relaxation, a sojourn of a few weeks or couple of months in a private or public hospital is advisable, where a well-equipped gymnasium is attached, with all the modern forms of appliances constructed for the remedial rectification of all forms

of spinal curvature. With this object in view, I have had fitted up and attached to the National Children's Hospital, Harcourt Street, Dublin, such a gymnasium, and have secured the services of a drill sergeant, well skilled in all forms of gymnastic exercises, who attends when required and instructs the different classes of patients repairing there for treatment. Even in cases where no actual curvature exists, such physical exercises are found most beneficial for the general improvement and muscular development of the *physique*.

The girl whose physical training is neglected always stoops. Stooping shoulders invariably contract the chest, and the flat-chested girl does not, as a rule, know how to breathe. She may say she breathes like everybody else, but if she has a narrow chest and stooping shoulders she certainly cannot breathe healthfully and legitimately. And, again, what is more to be desired and admired than an erect and graceful carriage in walking? Yet how few do we encounter in the streets who can be said to possess it! Everybody knows that those who have been trained to walk can cover double the ground with ease of those who shuffle along with head and body poked forward. An easy and vigorous gait is an accomplishment which no one ought to dispense with, and a contorted and contracted framework must necessarily impair, in the long run, the organs within. Fig. I shows a case of lateral curvature in a young girl of 13, where the curvature had existed only about three months, and where the treatment was very brief and successful. Fig. II shows a case of a youth of 16, where the curvature had existed for twelve months, and where the treatment was very long and tedious, although ultimately successful.

ON THE NATURE OF FRIEDREICH'S ATAXIA. (a)

By HARRY RAINY, M.D., F.R.C.P.Ed.

THE clinical features of the disease might be summarised as (1) an unsteady, reeling gait, and indecision in performing fine movements; (2) static ataxia and an irregular nystagmus, the latter being of importance in the diagnosis from locomotor ataxia; (3) choreic and athetoid movements; (4) slurred monotonous speech; (5) the development of deformities of the feet and spine; (6) such sensory phenomena as dulling of cutaneous sensibility and subjective sensations of pain or itchiness; (7) the mental condition may be normal, but defective intelligence, dementia, &c., are not infrequent; (8) the deep reflexes are abolished, but the knee-jerks may escape if the lesion does not extend so low as the third lumbar segment. Among the chief diseases with which Friedreich's ataxy might be confounded (but from which careful consideration of the above features usually enable the observer to differentiate it) were chorea, tabes, multiple sclerosis, cerebral syphilis, cerebral tumour, cerebellar ataxia, certain developmental anomalies, and hysteria. The greatest difficulty arises in connection with hereditary cerebellar ataxy, which one might almost say formed one of the two types (Friedreich's ataxia being the second) in which hereditary ataxia has gradually been

(a) Read before the Edinburgh Medico-Chirurgical Society, January 18th, 1905.

differentiated. Similar though the two probably were, both in their nature and origin in a developmental imperfection, and though intermediate cases occurred, it was better, both from a clinical and pathological standpoint to maintain a distinction between them. The following is a summary of the morbid changes observed in the case examined:—(1) In many of the peripheral nerves, especially of the lower limbs, the nerve fibrils had disappeared and their places were occupied by interstitial tissue. Similar changes were present in the cauda equina, limited here, however, to the sensory roots. Through an accident the posterior root ganglia were not available, but since the nerve elements were affected on both sides of them, it may be presumed that they were implicated. (2) The posterior columns of the cord were affected from the sacral segments upward, the degenerated areas corresponding to the root lesions, while endogenous tracts escaped except in so far as they were secondarily involved by contiguity to affected parts. (3) In the upper dorsal region some of the posterior roots were only partially affected, and there was a corresponding escape of fibres in the cord above this level. (4) The lower cervical nerves and their prolongations into the cord were markedly degenerated and replaced by interstitial tissue, but some of the upper cervical roots had escaped. (5) There was marked degeneration of the direct lateral cerebellar and crossed pyramidal tracts. The change in the latter had as its upper limit the level of the decussation—a fact also observed by Dr. Ormerod in a case which he examined. The lesion in the crossed pyramidal tract therefore begins where the spinal type of vascularisation commences, and where the tract comes into relation with the direct lateral cerebellar tract. (6) The direct pyramidal tract, the cells of the anterior cornu, and the motor nerve roots are normal. The sensory tracts above the nuclei of Goll and Burdach were unaffected, and its cerebrum and cerebellum were normal. The new interstitial tissue of the cord was of neuroglial origin; both in the posterior and lateral columns it often had a whorled appearance, suggestive of a common cause for the degeneration in both these positions. Where the change was most advanced the interstitial tissue was densely felted together, and tended to invade, and strangle the nerve fibrils in, neighbouring tracts. Amyloid bodies—according to Robertson and the author, degenerated mesoglia cells—were abundant in the degenerated areas. (7) The cord as a whole was smaller than normal at the level where degeneration was most marked. (8) The vessels, pial septa, and pia mater were normal, as also were the cerebellar peduncles. From his study of the case Dr. Rainy drew the following conclusions as to the pathology of Friedreich's ataxia: (1) A typical case of long standing may show no changes in the brain or cerebellum, hence lesions of these structures are not a necessary part of the pathology of the disease. (2) The similarity of the lesions in the lateral and posterior tracts justifies the belief that they have the same cause. (3) The cause is probably an inherent defect in the nerve elements. (4) The primary change is probably a disappearance of nerve elements, possibly due to defective myelin production or deficient longevity. (5) The nerve structures are replaced by neuroglia, first arranged in fibrils, then assuming a whorled appearance, and finally becoming a dense felted

mass. (6) The degeneration of the direct cerebellar tract may either depend on its own imperfect vitality or on alteration in the cells of Clarke's column. In this region, few healthy cells were found, but much stress cannot be laid on this appearance in a Müller hardened specimen.

We thus see how Friedreich's ataxia differs from other forms. In tabes, poisons conveyed by the lymph stream destroy the more sensitive nerve elements and stimulate the less vulnerable connective tissue. In cerebellar ataxia the lesion is nearly related in nature to that in Friedreich's disease, but its localisation is different; yet from contiguity, and from inherited nature of both diseases, mixed cases are but to be expected.

The Out-Patient Departments.

WEST END HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM.

Case of Disseminated Sclerosis of the Irregular Type, exhibiting a remarkable period of Latency.

By FREDK. S. PALMER, M.D., M.R.C.P.;

Assistant Physician to the Hospital.

H. J., æt. 35, unmarried, an army pensioner from the R.A.M.C., came to the out-patient department of the West End Hospital for Nervous Diseases on November 30th, 1904, under the care of my colleague, Dr. T. Outterson Wood, who very kindly passed him on to me.

The patient, a strongly-built man, 5ft. 5ins. in height, and weighing 12st. 1lb., gave the following history of himself:—He joined the Army in November, 1895, and eight months later (July, 1896), when acting as assistant ward master in the Military Hospital at Norwich, he was suddenly seized with an attack of vomiting, almost continuous for a week, and lasted at intervals for a fortnight; dimness of vision, and palpitation, followed soon afterwards by stiffness in the movements of both legs, but chiefly in the right; facial paralysis and external strabismus on the right side, with dull, aching pain at the back of his neck. From these initial symptoms he gradually, and apparently almost completely, recovered in from two to three months, and was passed for service in Egypt and South Africa. His habits have always been strictly temperate, although on more than one occasion lately he has been suspected of alcoholism from the peculiarity of his gait. He denies syphilis, but admits gonorrhœal infection five years ago. When serving in South Africa he had enteric, with one relapse at Johannesburg, and was in hospital for four months. On recovery, after a month's sick leave spent at Durban, he resumed his duties and continued to discharge them until February, 1904. Ever since the onset of his illness in 1896, he has been subject to transient attacks of vertigo, and has felt very nervous, more particularly when spoken to. For the last three years, he has had precipitate-micturition with some degree of incontinence and constipation. Eighteen months ago he began to complain of a dull pain over the sacral region which he attributed to rheumatism, and has never ceased. For the last twelve months he has experienced difficulty in rising from a chair, pains like cramp in both legs, and progressive difficulty and fatigue in walking. He has never had any sharp lightning pains in the limbs, girdle sensations, or crises since the gastric attack in 1896.

On examination, it was noticed that he walked with a staggering cerebello-spastic gait, and that his speech is slightly slow and drawing. Both pupils are equal, and react to light and accommodation. No nystagmoid movements are detected on lateral deviation. His vision is 6-36 with the right eye and 6-12 with the left, the difference being apparently due to a small nebula on the right cornea from three attacks of ulceration, presumably non-syphilitic. The temporal halves of both discs are markedly atrophic. All the other cranial nerves are normal, including both

divisions of the seventh. There is slight inco-ordination in the right arm, but an entire absence of volitional tremor. His knee-jerks are brisk, especially the right, which almost amounts to a clonus. The ankle-jerks are obtained, and there is a short, badly sustained clonus on the left side. The plantar responses are typically extensor on both sides. There is no definite Rombergism, nor any evidence of muscular atrophy. He complains of paræsthesia—numbness and tingling in both legs and the right arm, but no objective sensory changes can be discovered; tactile sensation and muscle sense are normal. The sphincters are affected; increased frequency and precipitate micturition; there is also some incontinence, and he is still very constipated. The cardiac sounds and impulse beat are normal, and his urine contains no trace of albumin or sugar. The features of interest in the case are briefly—

1. The absence of many of the so-called cardinal signs of the typical disease—nystagmus, intention tremor, and marked speech defects.

2. The sudden onset and marked severity of the initial symptoms. The patient states he was nearly blind for two or three weeks at Norwich, but before he resumed his duties his vision was nearly restored.

3. The remarkable period of latency or remission of the symptoms which enabled him to discharge his military duties, and even to take part in two exhausting campaigns, the second after an attack of enteric fever, although it is obvious that his recovery from the initial lesion was never complete.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.
MEETING HELD JANUARY 27TH, 1905.

The President, DR. FREDERICK TAYLOR, in the Chair.

MR. P. LOCKHART MUMMERY (introduced by MR. C. T. DENT) showed an Instrument for Examining the Rectum and the Sigmoid Flexure, and Drawings of Lesions seen through it. The instrument was a slightly modified Strauss' sigmoidoscope, by which a diagnosis might be made, so avoiding exploratory laparotomy.

MR. JONATHAN HUTCHINSON, jun., showed a Case of Extensive Syphilitic Necrosis of the Skull, causing an Intra-cranial Abscess, but without any Cerebral Symptoms. The man contracted syphilis at the age of eighteen, and was treated for a short while. Four years later he had rupia with severe pain in the joints, also iritis and posterior synechia in the left eye, and the treatment was resumed. He then remained free from symptoms for ten years, until September, 1904, when a lump formed on the vertex, followed by sloughing of a circular patch of scalp, then by necrosis of the skull beneath until the cerebral pulsations appeared, but the man was, meanwhile, able to work as a letter carrier, suffering neither from headache, giddiness, nor other cerebral symptoms until his admission to hospital. There the dead bone was removed by trephining, and a large sub-cranial collection of pus found between the skull and the dura mater.

DR. EASTES asked what treatment was proposed.

MR. FAGGE was of opinion that the drainage was imperfect, seeing that the internal area of necrosis was usually so extensive in these cases.

MR. HUTCHINSON, in reply, said that the case originally appeared to be a periosteal gumma which had softened and could be scooped out by the finger. He proposed to wait until the sequestrum was loose; as operation in this stage involved the danger of infecting some neighbouring vein.

MR. C. H. FAGGE showed a case of Uretero-lithotomy for Calculus. The patient was a girl, æt. 7, who, in 1901, had pain in the right loin with hæmaturia. In 1903 the same symptoms returned, and again in September, 1904, this time with a tender spot two inches to the right of the umbilicus; and under an anæsthetic a small, hard

mass could be felt. A calculus was found in the ureter about one inch below the kidney, which appeared normal. The calculus was removed, and the ureter and abdominal wall sutured. Healing followed, and the urine became normal a week after the operation.

MR. DOUGLAS DREW thought that, in all cases of ureteral calculus, the kidney should be explored for two reasons; first, the frequency of a renal stone being co-existent with the ureteral, and secondly the frequency of pyelitis, which needed draining.

DR. PARKES WEBER showed a case of Localised Flushing and Sweating on Eating, which, together with "strizæ patellares," followed appendicitis ten years ago. The symptoms had persisted since the former exhibition of the patient in October, 1897. When he began to chew solids a patch of redness immediately appeared on the left cheek, and the skin sweated. When this was at its maximum a smaller and less marked patch might appear in front of the right ear. Vinegar and water in the mouth, also mastication movements of the jaws, called forth the appearance to a less marked degree. Swallowing did not produce the phenomenon. After ceasing to chew, the sweating, and then the redness, slowly disappeared. The strizæ patellares were well marked, like the lineæ albicantes gravidarum, and were attributable to the flexed position of the knees when suffering from appendicitis.

DR. WEBER thought that an important factor, apart from the long illness—several months—was the great rapidity with which the boy grew at the age of sixteen. He asked for information on the effect of febrile illnesses on lineæ gravidarum.

SIR DYCE DUCKWORTH commented on the frequency of the occurrence of the lineæ after typhoid. He had published in this Society's "Transactions" a very marked instance of that, in which pains preceded the atrophy. Lineæ gravidarum certainly occurred in robust health, and he saw no reason for the introduction of any other factor than pressure.

MR. MCGAVIN said that the condition should be seen often in tuberculous ankylosed joints if Dr. Weber's explanation held.

DR. WEBER, in reply, pointed out that a continued pyrexial disease, gravely affecting nutrition, differed greatly from a local joint condition.

MR. CHARLES R. KEYSER showed a Case of Gottre in a boy, æt. 5. A lump appeared in the neck in September, 1904, with anorexia, occasional vomiting, and malaise. The swelling appeared to be a parenchymatous gottre, and increased to the size of a hen's egg. The boy had always lived in London, and no other member of the family had been similarly affected. The tumour rapidly diminished under treatment by iodine and iodide internally, and mercury iodide externally.

MR. CHARLES R. KEYSER showed a Case of Recklinghausen's Disease. The man, æt. 38, had all his life a number of small, rounded, subcutaneous tumours, which were steadily increasing in number. He said that one brother was similarly affected, and that his mother died of the disease. The tumours were all soft and absolutely painless, there were two areas of pigmentation on the trunk, but there were no signs of malignancy nor of nervous disease.

DR. BATTY SHAW asked for Mr. Keyser's definition of von Recklinghausen's disease. He had shown a similar case on the previous night at the Harveian Society, in which nerve tumours, an essential part of the disease, were present.

MR. MCGAVIN referred to the relation between the disease and malignancy. He knew of a case where multiple fibro-sarcomata had developed.

DR. WEBER wished to know whether any of the tumours had been microscopied.

SIR DYCE DUCKWORTH said that the case shown was an ordinary one of molluscum fibrosum. Dr. Fagge had given an excellent account of these cases, and had described various complications such as gastric dilatation and mental defects.

MR. KEYSER, in reply, said that Dr. Walsham, in

1899, had described a spindle-celled sarcoma of the neck, which had pressed on the brachial plexus. Mr. Alexis Thompson had collected a series of cases in which sarcomatous degeneration had supervened. He defined Recklinghausen's disease in a broad manner, and held that many varieties, of which his case was one, existed. The three most important features were subcutaneous nerve tumours, molluscum fibrosum and pigmentation. He had not removed any of the tumours, because such a procedure often led to increased growth and even to sarcomatous degeneration. The commonest mental defect was a stammer. Diarrhoea was frequent in these cases, but he did not know of the occurrence of gastric dilatation.

Dr. BATTY SHAW showed two cases of Acromegaly. One was in a man, *æt.* 36, in whom enlargement of the fingers and hands had been noticed for four or five years, numbness and tingling for three years. A radiogram of the hand showed the changes in the phalanges. Eight or nine years ago the patient wore No. 6 boots, now No. 8, the great toe was markedly enlarged and the skin thicker. The skull had enlarged, the eyelids were thickened, the nose broadened, the wrinkles on the face deepened, the voice hoarse, but the eyes and vision were normal, and there was no kyphosis. The patient was sometimes troubled by headache and by drowsiness. The other was in a woman, now in the Brompton Hospital for Consumption under Dr. Habershon, with disease of the left chest. The hands and fingers had enlarged, also the feet, the malar eminences were prominent, the lower lip protruded, also the eyelids, giving a heavy, dull expression. The tongue was enlarged. The patient suffered from headache, insomnia, and morning vomiting, but there were no eye symptoms. Photographs and radiographs further illustrated the case and distinguished it from pulmonary hypertrophic osteo-arthropathy. The skull radiograph showed the sella turcica distinctly, with a light area above it.

Dr. BATTY SHAW showed Bilateral Wasting of the Subcutaneous Tissues of the Face in a boy, *æt.* 10. This had commenced after the age of 2½. Three years ago he attended the Victoria Hospital for Children, and the wasting became more marked after measles two years ago. The wasting appeared to affect the subcutaneous tissues, not the skin, muscles, or bone. The condition was bilateral. There was no muscular paralysis nor wasting in any other part. The patient had had no illness, except some slight rheumatic symptoms and choreic movements.

Mr. W. G. SPENCER showed a boy, three years after Removal of a Large Cystic Adenoma of the Left Kidney. In the summer of 1901, when the boy was *æt.* 12, the mother had first noticed the swelling, but she said he had always had a "big stomach." In January, 1902, the boy was first taken to Dr. Redmond Roche, who diagnosed the case. Abdominal nephrectomy was done by a T-shaped incision; some vascular adhesions to the diaphragm caused a temporary disturbance of respiration. The half of the specimen in the Westminster Hospital Museum was shown, and Mr. Shattock's description of the other half in the College of Surgeons Museum was appended.

Mr. JONATHAN HUTCHINSON, jun., commented on the occurrence of a congenital cystic disease, which was usually bilateral and complete, in one kidney only and in only part of that. In the general cases, partial removal of the disease was quite justifiable. He had done this with success in one instance.

Mr. W. G. SPENCER showed a child after Recovery from Infantile Paralysis of the Deltoid. When the subject of nerve-grafting for such cases was before the Society in October last, the girl was in Dr. de Havilland Hall's ward, and could not then raise the arm from the side at all. The child had been kept under Dr. Hall's observation, and had had the arm rubbed and electricity used. She can now raise it easily above the head and seems to be recovering well.

Mr. C. H. FAGGE asked for the period between the onset and the beginning of recovery.

Dr. WILFRED HARRIS gathered that the affection followed an injury to the arm, and not an acute illness; this cast doubt on the diagnosis. The question of nerve grafting should not be entertained until reaction of degeneration had been present for at least three months, as recovery in these cases was so variable.

Mr. SPENCER admitted that the paralysis followed on an injury. What we wanted to know in these cases was which were going to recover and which not.

Dr. F. E. BATTEN showed a child with Graves' Disease and Myxœdema at the age of ten. A fat child, with a pale, puffy face and hands, squeaky voice, and placid, slow manner, had considerable thyroid enlargement and a pulse-rate between 118 and 140; also a waddling gait. Other signs of nervous or visceral disease were absent. Thirteen weeks ago the child fell downstairs; eleven weeks ago headache came on with such severity that the child had to be kept in bed; six weeks ago disturbance of gait came on.

SIR DYCE DUCKWORTH showed a case of Xanthoma Diabeticorum. The patient, a clerk, *æt.* 23, had diabetes in September, 1904. A sister died of the disease, *æt.* 31. He had been first of all treated privately, then at St. Thomas's Hospital, and was admitted to St. Bartholomew's in December. On December 24th a large number of small papules appeared over both elbows. The papules were hard, shotty, and a small amount of yellowish material could be pressed out. On the 31st the papules had increased in size, and fresh ones appeared symmetrically over the back, buttocks, knees, and scantily on the face. On January 25th the papules were increasing in size and number. Amount of urine averages 100 oz. per diem. Sp. gr. 1034. Perchloride of iron reaction present. Sugar on admission 25 gr. per ounce; on January 25th 12 gr. per ounce. Body-weight on admission 8 st. 6 lbs.; on January 25th, 7st. 8 lbs.

SIR DYCE DUCKWORTH commented on the extreme rarity of this condition. It hardly ever occurred apart from diabetes, though it had been recorded in diabetes insipidus. It was commoner in males. The remarkable feature in his case was the very sudden onset when under observation. The condition was certainly not due to glycœmia, but probably to some other toxic substance; Dr. Luff had suggested β -oxybutyric acid.

Mr. EDRED M. CORNER showed a Case eighteen months after Fracture of the Scaphoid, Semilunar, and the Cuneiform Bones of the Carpus. The hand had been caught in a printing machine and twisted. He was told at a hospital that the injury was a dislocation, and was treated with splints. Weakness and deformity persist. A skiagraph showed that the semilunar bone had been comminuted, and the fragments displaced forwards; so also the scaphoid, except the radial portion, which remained in position. The portion of the cuneiform nearest the radius had been fractured. The distal row of carpal bones was displaced backwards.

ROYAL ACADEMY OF MEDICINE IN IRELAND. SECTION OF MEDICINE.

MEETING HELD FRIDAY, JANUARY 20TH, 1905.

SIR J. W. MOORE in the Chair.

PARATYPHOID FEVER.

Dr. PARSONS read notes on three cases of continued fever in which for some time the diagnosis was obscure. They all occurred in the same building and about the same time. The first proved to be a severe case of typhoid fever, and gave a definite Widal with Eberth's *Bacillus typhosus* on the twelfth day of the illness. The pyrexia lasted for fifty days. Case II, though tested on three separate occasions by different strains of *Bacillus typhosus*, gave no reaction, but gave very definite clumping with Gärtner's *Bacillus enteritidis* on two occasions, and with different strains. The pyrexia lasted twenty-one days. Case III was also negative with *Bacillus typhosus*, but positive with Gärtner.

The pyrexia lasted fourteen days. In all cases the subjective phenomena were headache and malaise. The objective signs were temperatures of 102° to 104° F., while the average pulse was only 90. In none of the cases was the spleen palpable, and only in No. 1 were any spots visible. Cultures were made from the urine and faeces in the latter cases, but the *Bacillus enteritidis* was not isolated. Dr. Parsons referred to cases of paratyphoid reported in *The American Journal of Medical Science*, and pointed out the necessity for isolating various strains of paratyphoid bacilli, against which the blood of obscure cases of continued pyrexia might be tested. Owing to the general absence of ulceration in paratyphoid fever, he was of the opinion that the diet need not be quite so rigid as in typhoid fever.

Dr. CRAIG described minutely the fatal case of paratyphoid which he had seen. He admitted the man from his dispensary, who was then looking very like typhoid. His temperature was 103.2°, pulse 100 and respirations 24. He had three liquid yellow motions and developed a rash, which at first consisted of rose spots, but later became dark, like typhus. The tongue was thickly coated, cerebation slow, and he refused food. The abdomen was distended. He became delirious, and seventeen days after the rigor which had ushered in the illness he died. The pulse averaged 95 to 100, and respirations 24. The spleen was easily noted to be enlarged. *Post-mortem* there was no evidence of enlargement or ulceration of Peyer's patches, the greater part of the ileum was in a state of acute inflammation. Dr. White examined the blood on the fourth day after admission. He tried a Widal, and got clumping with a dilution of 1 in 25. There was no evidence of Eberth's bacillus, but one of the forms of *Bacillus enteritidis* had caused the illness. In a number of cases hæmorrhage from the bowel had been observed.

Dr. TRAVERS SMITH said he had seen two cases which he thought were paratyphoid. One was a woman, æt. 32. On admission her temperature was 103°, pulse not markedly quick, no diarrhoea, enlarged spleen, nor rose spots; but there was great abdominal distension, and she was rather livid. The blood was negative to Widal. She died in about a week, and *post-mortem* there was no trace of disease in Peyer's patches, nor was the spleen enlarged. In the other case the tongue was coated, spleen a little enlarged, pulse rather quick, and the temperature up. The blood was negative to Widal. The fever gradually subsided; but for ten days the spleen remained large, then it subsided, and she got perfectly well. He suspected paratyphoid, but had no proof of it, as the special blood reaction had not been tested for.

Dr. MELDON thought that in paratyphoid one should be just as careful with regard to diet as in typhoid, as in some cases there had been hæmorrhages, showing disease of the intestine. The presence of a large ulcer had been reported in one case.

Dr. FANNIN said he had had a case of a boy, æt. 17, who had a continued fever, the characters and course of which were the same as typhoid. There were no rose spots nor enlarged spleen. He had acute laryngitis. At that time Widal was negative. Ten days after the temperature had become normal a relapse occurred. It followed a typhoid course, the laryngeal symptoms were renewed, rose spots appeared, and the spleen became palpable. He became very ill, and was removed to hospital. Two or three days afterwards symptoms of perforation occurred. An operation was performed, and a perforated ulcer discovered, but the patient did not recover. Dr. Thompson was satisfied that the ulcer was like an ordinary typhoid one. In that case, then, repeated examinations of the blood had failed to give the Widal reaction. The course of the illness resembled typhoid, and a fatal result occurred after perforation, therefore it was possible that some forms of paratyphoid could have the definite ulceration of Peyer's patches.

Dr. KIRKPATRICK said he would like to ask whether any differentiation had been made in the clinical history

of the fevers which were due to the different groups of paratyphoid bacilli.

Dr. McWERNY discussed the cases from a pathological point of view. He said that one would be inclined to call Dr. Parsons' second and third cases, cases of Gärtner infection. It had been mentioned that the blood serum failed to agglutinate typhoid, but did Gärtner's bacillus. That carried an indication of Gärtner infection, which was not quite the same thing as paratyphoid. The Gärtner bacillus was not quite the same type as the alpha and beta groups of paratyphoid, but presented certain differences. It was quite possible that the second and third cases were paratyphoid, but the bacilli would have had to be isolated and their characters fully tested. What he found lacking in the pathological description was a statement of the different dilutions which were employed.

Dr. PARSONS, during his reply, said that intestinal lesions had been mostly found to be in abeyance during paratyphoid, and thought it was not so necessary to restrict the diet as in typhoid. There was no difference in the clinical course of the fevers produced by the alpha and beta groups. In his communication he had used the term paratyphoid in its widest sense, and had included Gärtner's bacillus in the term, although he was aware that there was a tendency to restrict the term to a small group of bacilli.

TWO CASES OF LARGE WHITE KIDNEY.

Dr. PEACOCKE described the clinical history of two cases which had been recently under his care. The symptoms of each case were very similar, and were, briefly—anæmia, universal dropsy, diarrhoea, and scanty, highly albuminous urine, containing numerous casts. The kidneys were found to be macroscopically large white kidneys; but, microscopically, while both showed some increase in connective tissue, one was found also to show commencing amyloid degeneration. He discussed the causation of chronic parenchymatous nephritis, and was in favour of regarding the disease as originating always in a previous attack of acute nephritis. The cases described as chronic from the beginning were either cases in which the acute attack had been overlooked or were examples of lardaceous degeneration. He considered the best classification of diseases of the kidney associated with albuminuria was as follows:—(1) Nephritis, acute and chronic; (2) granular kidney; (3) the kidney of lardaceous disease.

Dr. McWERNY.—With regard to the microscopic specimens, the impression he got from those of the second case was that it was far from certain whether it was really amyloid degeneration or hyaline. The section showed hyaline change of a portion of the glomeruli, but there was no differential staining to show whether there was also amyloid change. The question might have been answered by seeing whether the middle coat of some of the smaller arteries was affected in the same way, but he had failed to see this change. Therefore, he was inclined to think it was hyaline degeneration. The other section also showed hyaline changes in the glomeruli, but not to the same extent. A pathologist would diagnosticate the second case as early chronic interstitial nephritis.

Dr. TRAVERS SMITH said that his experience went to show that chronic parenchymatous nephritis was insidious in onset. The history of the onset was often misleading. One saw a good many cases of acute nephritis occurring during scalatina; he had never seen these cases coming back suffering from chronic parenchymatous nephritis, and he did not think it could be common. One of Dr. Peacocke's cases exemplified the difficulty of diagnosticating a mild acute case from chronic parenchymatous nephritis, and this was a serious question from a prognostic point of view. In both you might have extensive dropsy, the quantity of urine diminished, hyaline and epithelial casts, blood—all this made it very difficult to come to a diagnosis, particularly in those cases where there was no antecedent cause, such as scarlatina.

Dr. KIRKPATRICK said that in examining micro-

scopic sections of kidney disease it was very important to examine all the fields carefully and to make large sections. When large portions were examined, although they differed in one part from another, yet many of the kidneys had various points in common. A classification thus became possible; but he thought that any classification based on histology alone was unsatisfactory. All of these diseases were more or less of the nature of inflammations, and the effect of the inflammation was evident in one in the parenchyma, in another in the interstitial substance. There were many cases where the differences were so pronounced that one was justified in putting them into different classes; but when one examined further the changes were completely progressive, and from the most typical acute nephritis to the most well-marked chronic case there was no distinct breach of continuity on microscopic examination.

Dr. WHITE said that he had had an opportunity of applying the special tests for amyloid substance to the sections, and found that a small portion was really amyloid, though the major portion was hyaline.

Dr. DRURY said he did not know that he could agree with the statement that many cases of chronic parenchymatous nephritis resulted from acute. He had been for a long time trying to find *bona fide* acute cases which turned into chronic, but had never found them. He thought that many of the cases of chronic nephritis, secondary to acute, were really chronic cases in which acute exacerbations had come on during already existing disease. You had to know the history beforehand. He thought that Dr. Peacocke was inclined to lay too much stress on amyloid change as being the primary cause of many chronic tubular cases.

Sir J. W. MOORE quite agreed that chronic parenchymatous nephritis seldom followed on scarlatinal nephritis, which was usually followed by complete recovery. With regard to causes, he did not hesitate to assign alcohol as of prime importance, though various causes co-operated, as cold and damp. He also thought the mode of death was important in these cases. The toxæmia was comparatively infrequent in very dropsical cases, whereas in the other cases it was very likely to cause death. The heart was really the crucial point in the management of nephritis, for as long as it could compensate there was some chance of the patient getting on.

Dr. PEACOCKE, in his reply, said that the cause of death in both cases was nothing very definite. Asthenia was the best term to use for it. In these acute cases which developed into chronic there was often an interval of some months before the latter symptoms came on. He did not agree that the symptoms of amyloid disease were so apparent that you could always come to a diagnosis. He believed that amyloid change did occur even when there was not much suppuration. There was no doubt that very often in those cases which were described as chronic parenchymatous nephritis and large white kidney, there was marked amyloid change.

LIVERPOOL MEDICAL INSTITUTION. MEETING HELD JANUARY 19TH.

Dr. JAMES BARR, President, in the Chair.

Dr. W. BLAIR BELL exhibited and demonstrated the use of the following instruments:—(1) Combined peritoneum forceps and wound retractor; (2) complete infusion apparatus, with improved venous cannula.

Mr. ROBERT JONES and Dr. DAVID MORGAN presented an analysis and radiographic illustrations of sixteen cases of bony deposits following dislocation of the elbow-joint under their observation. These deposits had followed simple dislocation, unaccompanied by fracture, and were not associated with myositis ossificans progressiva. They differed from myositis ossificans due to local irritation, and their occurrence in presence of a fracture was not associated with callus display. The periosteum was believed to be the origin of these bony deposits. A series of radiographic lantern

slides depicted their growth, from slight shadows to dense bony formation. The diagnosis and prognosis were discussed, and microscopic slides shown to demonstrate their true bony nature as distinct from calcareous changes.

Mr. W. T. CLEGG read notes of a case of CEREBELLAR ABSCESS which occurred as the result of acute ear trouble. The clinical history of the case was given, and the different diagnosis between temporo-sphenoidal and cerebellar abscess discussed. An operation had been performed, but without relief to the patient. At the autopsy a large abscess was found in the right lateral lobe of the cerebellum, the infection having travelled from the ear along the sheath of the auditory nerve. There was no meningitis.

Mr. CLEGG also related a case of acute labyrinthitis in a child, 2 years and 8 months of age, in which the symptoms closely resembled those of meningitis. After recovery, deafness persisted. There had been no discharge from the ear.

Dr. NATHAN RAW read a paper on "Some Points in the Diagnosis and Treatment of Typhoid Fever," based on an observation of 362 cases treated in hospital during the last sixteen years. He referred in detail to the great difficulties in diagnosis which many cases presented in the early stages of the disease, and discussed the value of Widal's reaction as an aid to the practitioner. Hæmorrhage and perforation were the two most formidable complications, and a careful *resumé* of the symptoms of perforation of the intestine was given, as it was highly important to be able to diagnose its immediate onset, so that prompt operative measures might be adopted. In his opinion, the treatment of the future would be directed towards reducing the virulence of the bacilli and the onset of toxæmia, on the lines suggested by Professor Wright, or by the introduction of a serum. The cold or continuous bath treatment undoubtedly in other countries gave better results than any other, but he believed it would be some considerable time before it was generally adopted in this country in the treatment of typhoid fever.

Dr. W. CARTER considered Bieger's suggestion of feeding patients suffering from typhoid fever with pure peptones good, and he had carried it into practice for many years. Commenting upon Widal's reaction, he mentioned two cases in which it proved misleading.

Dr. W. B. WARRINGTON considered that even when made with much care, the serum reaction was not devoid of ambiguity, and the observer was from time to time left in doubt as to the positive or negative nature of the reaction.

Dr. N. E. ROBERTS was of opinion that the mortality of enteric fever in Liverpool, when treated in hospital under modern conditions, would average about 12 per cent. He based this on his experience of close upon 2,500 cases treated at the city hospitals since 1892. The mortality of this disease is greatly influenced by the class of patient under treatment, and, as illustrating this point, Dr. Roberts said he had never lost a nurse or any member of the hospital staff from enteric fever at the Grafton Street or Parkhill Hospitals since he joined these institutions in 1892.

The President, Dr. J. Hill Abram, Dr. T. R. Bradshaw, Dr. A. G. Gullan, Dr. C. J. Macalister, Dr. R. S. Archer, and Dr. R. J. M. Buchanan also took part in the discussion.

NORTH-EAST LONDON CLINICAL SOCIETY. CLINICAL MEETING HELD THURSDAY, FEBRUARY 2ND, 1905.

Dr. R. MURRAY LESLIE, President, in the Chair.

THE following cases were exhibited:—

Dr. A. J. WHITING showed an infant, æt. 6 weeks, with Congenital Hypertrophic Stenosis of the Pylorus. The child was manifestly ill, and some abdominal distension had been observed over the stomach. Vomiting was frequent and had persisted, off and on, ever since

birth. The bowels were constipated. A rectal examination revealed nothing abnormal.

Mr. HERBERT CARSON considered that intestinal obstruction could be excluded. He recommended most careful watching, and that lavage should be practised for the first few days. If at the end of a short time improvement did not set in, the advisability of operative measures might then be thought of.

Dr. G. P. CHAPPEL thought that the condition of the pylorus after taking food should be observed. He would be inclined to give a more prolonged trial to washing out the stomach.

Dr. CHAPPEL also showed a case of Abdominal Tumour in a little girl, *æt.* 2½. A provisional diagnosis was suggested of sarcoma of the kidney with a secondary deposit in the omentum. The swelling had been noticed for three months.

Dr. J. W. HUNT thought the case was one of renal tumour, most probably a hydatid.

The PRESIDENT showed two cases of Pneumothorax, one in a man the subject of phthisis, in whom the condition had practically cleared up. The other case was one of Hæmo-pneumothorax, which had been previously exhibited before the Society. A recent exploration with the syringe revealed the fact that the blood was slowly becoming absorbed, its place being apparently taken by clear serum.

Dr. D. FOGARTY remarked that the latter patient had been under his care since his discharge from the hospital. He had been taking suprarenal extract together with potassium iodide, and his whole condition had certainly much improved.

Dr. NORMAN MEACHEN exhibited a girl, *æt.* 15, the subject of Cheilitis associated with a Localised Hyperidrosis affecting the central parts of the face. The upper lip was swollen and the mucous membrane was chronically inflamed, the condition having lasted for one year. Her mental condition was somewhat dull. There was a well-marked tuberculous family history. The opinion of the exhibitor was that the lip was strumous in character.

Dr. F. J. TRESILIAN (Enfield) showed a man, *æt.* 44, with a large tumour at the back of the neck. He had had it for two years, and he said that he found it somewhat useful for carrying weights upon! The swelling was spherical, of a semi-solid feel, with an ill-defined sense of fluctuation, and was about ten inches in circumference.

Mr. CARSON considered that the tumour was of the same nature as a wen, and that it would most probably be found to consist of a soft, fibromatous and vascular tissue.

Dr. R. MURRAY LESLIE also showed a girl with right-sided hemiplegia in whom recovery was slowly taking place.

Dr. D. McASKIE showed a man, previously exhibited before the Society, the subject of Leukæmia. The X-rays had caused great diminution in the volume of the spleen. He now presented a bronzing of the skin, chiefly attributable to arsenic which he had been taking at the same time.

The following pathological specimens were exhibited

1. Dr. E. HOOPER MAY: A Perforated Duodenal Ulcer. The chief interest lay in the unusual clinical features of the case. The patient was a child, *æt.* 12, in whom the symptoms began with vomiting and diarrhœa. There was practically no pain in the upper part of the abdomen. The appendicular region was first explored at the operation, but her condition became so grave that nothing more could then be done.

2. The colon from a case of Pre-Natal Intestinal Obstruction.

3. Dr. C. R. SALISBURY read notes of a case of Tuberculous Testis that he had removed by operation.

4. Dr. C. E. HUTT showed an infant with a large Meningo-Encephalocele which had caused some difficulty as regards the diagnosis of the presentation. The child lived an hour after its birth.

5. Dr. W. H. PAINE exhibited a specimen of the so-called Intra-Uterine Amputation, together with skiagraphs illustrating the condition.

6. Dr. CHAPPEL showed the brain from a case of cerebral hemorrhage, causing left-sided hemiplegia without aphasia in a woman.

THE SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.

MEETING HELD ON FRIDAY, JANUARY 20TH, AT 11 CHANDOS STREET, W.

DR. PERCY LEWIS (Brighton) in the Chair.

Mr. F. JAFFREY showed two cases of Volkmann's Contracture, which had occurred in the right forearms of two girls, *æt.* 2 and 7, as a result of fractures. In each instance the splints had produced pressure sores. He was in favour of lengthening the flexor tendons by operation.

Dr. W. H. KELSON showed a boy, *æt.* 6, from whom he had successfully removed a fibrous growth on the right vocal cord. On recovering from the anæsthetic, the voice was found to be clear. He also showed a boy, *æt.* 12, whom he had treated by the galvanocautery for lupus of the epiglottis and left vocal cord, the voice returning. The upper part of the epiglottis was wanting and its stump had been covered with red papules. The ventricular bands, left vocal cord, and anterior commissure were similarly affected. There was no history of syphilis, no evidence of lung disease, and no tubercle bacilli in the sputa.

Dr. L. GUTHRIE showed a girl, *æt.* 12, whom he brought before the Society in December, 1903, as a case of aortic stenosis. He was still of the opinion that the physical signs indicated aortic disease and thought that there might be some congenital malformation in the neighbourhood of the aortic valves. The girl was highly rheumatic. As on the former occasion, various opinions were expressed on the physical signs and the conclusions to be drawn from them. The lack of unanimity was somewhat remarkable.

Dr. A. MORISON showed a boy, *æt.* 10, with marked Double Aortic Disease and Mitral Regurgitation. There was an indefinite history of rheumatism.

Dr. C. CARPENTER showed a child with Congenital Pulmonary Stenosis and probably a Patent Septum Ventriculorum. The child had come under his care for an attack of catarrhal jaundice.

Mr. DONALD ARMOUR brought forward a boy, *æt.* 4, with a Peno-scrotal form of Hypospadias, with a view to eliciting the opinion of members of the Society as to the best kind of operative treatment and the best age at which to carry it out.

Dr. E. PRITCHARD showed a girl, *æt.* 6, to illustrate hæmophilia, hereditary in the male line for two generations, and evidenced in the third in a severe form in a female. The child had suffered from severe attacks of epistaxis since babyhood. Her father and grandfather were affected, but no other members of the family. He also showed a boy, *æt.* 14, with Congenital Ptosis of the left eyelid.

Mr. G. PERNET showed a case of Generalised Lichen Planus, of three months' duration, in a boy, *æt.* 6. The boy had a "tower skull," ptosis with absence of the upward movements of the eyes, and a highly arched palate. He also showed a child, *æt.* 4 months, recently vaccinated, with a Circinate Gyrate Erythema Multifforme.

Dr. J. G. EMANUEL (Birmingham) showed a most remarkable specimen of Congenital Multiple Occlusions of the Small Intestines, from a seven months' infant, who died nine days after birth. The child had vomited since birth; but no stool had been passed. As the result of an enema a large motion of meconium was passed. There was complete atresia of the bowel at the duodeno-jejunal juncture, the duodenum being much hypertrophied and dilated, being larger even than the stomach. In two other places the jejunum was completely absent for about half an inch. In five other places, in the jejunum and upper part on the ileum, the gut was completely occluded by annular

constrictions. There were no signs of intra-uterine peritonitis.

Mr. A. T. MARSHALL showed a specimen of a collar stud impacted in the œsophagus and perforating the trachea. It was removed *post-mortem* from a female infant, æt. 7 months. It had produced consolidation of the right lung, ulceration into the trachea an inch above the bifurcation, and pus in the trachea and œsophagus.

The cases were discussed by Drs. Percy Lewis, W. Ewart, L. Guthrie, F. J. Poynton, H. Skelding, C. W. Chapman, R. Hutchison, A. Morison, Edmund Cautley, G. A. Sutherland, C. O. Hawthorne, Mr. Donald Armour, and Mr. G. Pernet.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, February 5th, 1905.

TREATMENT OF ŒDEMA.

THE œdema of visceral maladies is the most amenable to active therapeutic treatment, says Prof. Huchard. For cardiac œdema the milk diet, drastic purgatives, digitalis, theobromine, and blood-letting are the arms to be used by the practitioner, according to the circumstances of the case. In cases of dilatation of the head, where the œdema increases in spite of digitalis and the milk *regime*, a reduction in the quantity of the liquid absorbed is frequently very beneficial—a pint and a half of milk mixed with the same quantity of water given daily for two or three days. Œdema in disease of the blood-vessels (arteries) is rare, but acute œdema of the lungs in affections of the aorta is frequently observed; it is possible, however, that the renal organs play a certain part in the production of this œdema. The treatment consists in abundant blood-letting and subcutaneous injections of caffeine or camphorated oil.

Œdema in venous affections is much more frequent, as in the case of varicose veins, and should be treated by the elastic bandage, massage, and the internal and prolonged administration of tincture of *hamamelis virginica* (5 drops twice daily).

Œdema caused by compression, cancerous embolic parasites (filiaris) of the lymphatic vessels receives the name of elephantiasis, and the treatment varies according as the malady is acute or chronic. In the acute form, the patients keep to bed, the parts are sprayed and acupuncture is done. In the chronic form, massage, the application of an elastic bandage and rest are all that can be done.

Œdema preceding ascites in cirrhosis of the liver appears frequently at a very early stage, and before any functional trouble due to the malady. When the lower limbs are sweated and the heart and kidneys are generally healthy, while the patient is thin and the conjunctiva has a sub-icteric tint, commencing cirrhosis may be suspected and an alimentary *regime* instituted—milk and farinaceous diet.

The œdema of renal affections is easily detected in acute nephritis as it is general and precocious; in the chronic form it is found in the eyelids and around the ankles. The treatment of renal œdema has received a considerable impulse through the studies of Achard and Vidal, who showed that salt was the dangerous element. The œdema is due to the retention of chlorides in the tissues, consequently the salt must be suppressed in the food. The patients can be allowed a quarter of a pound of meat, and the same quantity of bread (without salt), potatoes, eggs, rice, &c. The œdema disappears as readily as with the milk diet, the only advantage of which is that of containing a very small amount of salt per quart. As to the medical treatment it consists in giving theobromine. It is not always expedient to allow patients meat, as frequently under its influence the diuresis diminishes while the chlorides and the urea are but imperfectly eliminated. In any case where meat is allowed, ten grains of theobromine three times a day should be ordered.

Besides theobromine, other medicinal agents can claim a place in the treatment of chronic nephritis,

amongst which digitalin takes the first place when the malady is complicated with cardio-sclerosis with *bruit de galop* and tendency to dilatation.

The dose should be very small ($\frac{1}{10}$ milligramme) and continued for ten days every month. These weak doses tonify the myocardium without fatigue to the organ. All other drugs, caffeine, squills, spartein, strophanthus, &c., have much less value. The means of elimination of œdema are chiefly through the urinary tract and the intestines. If the heart is not too dilated, diuretic infusion may be given with the milk and theobromine, while drastic purgatives act well by depleting the possible œdema of the brain. General blood-letting may be also advised if the patient is strong enough to bear it.

Sudorifics render but doubtful service, but the method recommended by the Lyons school might be tried—rubbing the chest and back with an ointment of pilocarpine:—

Nitrate of pilocarpine, 2 grs;

Vaseline, 3 oz.

The parts are covered with cotton wool and gutta-percha sheet until profuse sweating takes place.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, February 5th, 1905.

At the Medical Society, a

MUSCLE ARTIST

was shown by Exc. von Bergmann, who by constant practice had learned to move individually as well as collectively or in different combination the muscles of his trunk, and especially those of the abdomen.

Hr. Guttman showed a case of

PRIMARY TUBERCULOSIS OF THE CONJUNCTIVA cured. The patient was a child, and the tuberculosis was contracted through the instillation, as was supposed, of drops. The diagnosis was rendered certain by the production of tuberculosis in rabbits and guinea-pigs through implantation of portions of diseased mucous membrane from the eye. The treatment consisted in cauterisation of the diseased surfaces with hot air, and success was attained in this way without causing any ectropion.

Hr. Gluck related a case of

CEREBRAL CYST.

In 1891 he had operated through the temporal bone for otitis and for three or four years afterwards the patient, a boy, had remained quite healthy. Then epileptiform convulsions commenced, which became more frequent. There was also headache, and at last some dulness of intellect, but no symptom of compression. The old cicatrix was opened, the bony flap thrown back, when he came upon a large cyst, which corresponded to the site of the old abscess. He emptied this and sutured up the cavity until only room was left for a small drain. Recovery. The absence of pressure symptoms was explained by the elasticity of the old cicatrix.

Exc. von Bergmann related a case of

SPURIOUS TRAUMATIC MENINGOCELE.

A man had suffered from slight injury to the skull eight years ago, and fifteen months ago a serious injury. The soft parts healed rapidly on both occasions, but after the last injury slight symptoms of disturbance remained. A year later a swelling suddenly appeared in the night over the right side of the head, and caused severe headache. The patient presented himself at the Klinik with a soft, fluctuating, tender, non-pulsating, and non-compressible tumour. By bending forward the pain was increased, but not the size of the tumour. It was a case of spurious traumatic meningocele, which had hitherto been observed in children only. Through an opening in the skull, a dilated emissorium Santorini, blood poured through out of the longitudinal sinus under the periosteum, so that the tumour filled with blood communicated with the sinus. Puncture showed the presence of fluid blood only. After some amelioration the blood re-collected. A bony wall

was felt at the circumference of the tumour, such as was felt in cephalhæmatoma. For radical cure closure of the opening in the bone was necessary, but this the patient declined.

Hr. E. Lessu spoke on the

FINSEN LIGHT TREATMENT OF LUPUS.

The question was approached from two points—(a) Was lupus absolutely curable by it? (b) Was a good cosmetic result obtained from its use? With regard to the first point, a definite answer was difficult as the treatment had only been employed during the past ten years; but it did seem as if recurrences were longer in taking place than formerly.

As regarded cosmetic effect, better results were obtained than by any other method, as only the diseased structures were affected by the treatment, and it in reality acted electively. So far as the lupus had destroyed healthy structures, these, of course, could not be replaced; but the treatment did not affect the healthy tissues as all other methods did. The X-rays appeared to act in the same way. Neither kind of ray had any specific action on the tissues. The action was merely that of a caustic, but the dose could be so accurately measured that the effect fell only on the diseased structures.

The Finsen treatment did not always lead to the desired result, and then other methods had to be tried in addition, such as cauterisation, hot air, X-rays, &c. X-ray treatment was a useful adjunct, but it was not suitable alone for the treatment of the disease.

Hr. Liebreich originally had the idea of raising the cells to higher vital activity by means of medicines. He used cantharides for this purpose long ago, and, in order to get more accurate dosage, in the form of cantharidate of soda. He gave it at first subcutaneously, but later on with equal success by the mouth. He had cured cases of lupus in this way that had remained seven and eight years without recurrence. He laid stress on his methods of examination, glass pressure, and phanerescopy. Cases of lupus shown as cured by the Finsen treatment yet showed nodules of the di ease under phanerescopy. There was no case of actual cure up to the present. It had even been observed that under the Finsen treatment new nodules were formed. Good cosmetic results were obtained; that was conceded, and it was a suitable aid towards attaining recovery. If the disease was to be definitely cured, however, it must be attacked from within, after that the Finsen or a surgical method of treatment might be brought into use.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, February 6th, 1905.

PERITONEAL RESISTANCE AGAINST INFECTION.

BORCHARD has been making further experiments with intra-peritoneal injections of nuclein serum from the horse and common salt with the object of increasing the resistance to poisons in the peritoneal cavity when operations are performed. If a nuclein salt be injected with a physiological solution of common salt eight hours before the operation, the result will be a perfect success. He calculates that the immunity lasts about four days.

Schmidt has carried this theory into the realm of practice by injecting five to ten cubic centimetres of sterilised equine serum in 250 to 500 cubic centimetres of a 0.9 per cent. solution of Na. Cl. into the peritoneum before operating on the abdomen. For this purpose he has constructed a special trocar whereby the wounding of the bowel can be avoided. His practice is to inject the fluid 17 to 19 hours before he operates.

LEUCONOSTOC HOMINIS.

At the Prague meeting Hlava gave a history of his experiments with leuconostoc, which, he said, were common to the buccal cavity and were stimulated into activity by different inflammatory processes such as coryza, angina, scarlatina, and morbilli, which increased their presence in the blood and produced toxic symptoms.

Whatever be their significance their presence is widely diffused, and though they may not be the true cause of the disease they are strongly connected with its advent. His experiments were confined to the genus of streptococci, and he demonstrated two cases of typhus exanthematicus to show how the convention of the leuconostoc hominis to the blood was accomplished. In the blood of these patients the germ was found coiled up and did not exceed the size of one-sixth of a red blood corpuscle; in another patient it was spermatozoidal in shape.

In the spleen blastomycetes, or spores representing that germ, were cultivated and produced the bacteria. Another form which this leuconostoc takes is the "tumeur perlée," at the base of the brain. The clinical symptom of this mysterious agent was that of bulbar paralysis. In a case of carcinoma of the bronchial walls having no typical infiltration of the subclavian gland, the same condition was found in the blood. In another case of peri-tracheal gumma, where tracheotomy was performed, a similar state of the blood was observed.

UTERINE MYOMA.

Rubeska gave a history of the different methods of operating on the uterus for myoma and polypi, or enucleation itself. He had performed the vaginal operation 50 times without a single death; laparotomy 71 times, with 4 deaths, or 5.6 per cent.; 2 cases he lost after supravaginal amputation from heart failure, and another two after total extirpation from a pulmonary embolus with subsequent sepsis. Rubeska recommends the vaginal method as the least dangerous and most easily performed. There are conditions when enucleation or amputation may be better performed by the abdominal method, but where practicable the vaginal is to be preferred. In young females, where the parametrium and collum of the uterus are to be retained entire, the vaginal operation is quite impracticable. Pitha said that he always preferred the abdominal operation as a more radical cure for the disease. The vaginal method was nothing more than a palliative operation and could not be accepted as a radical cure. Since the commencement of his abdominal operations his mortality had fallen from 24 per cent. to 11, which he considered a favourable figure.

MOLA HYDATIDOSA.

Ostréil related the history of a case of a racemose tumour which he had removed from a female, æt. 43, who had previously given birth to six children. She was admitted into hospital with great pain in the abdomen and a profuse discharge from the uterus. On palpation the uterus was found to be large and containing a fluctuating body. The hæmorrhage soon became profuse and associated with severe rigors, which induced him to commence dilatation of the neck by means of Bossi's instrument, which was completed with a "metreurynter." After twenty-four hours she was delivered of a racemose tumour weighing 1,600 grammes. The patient finally recovered without any untoward circumstances. He presumed that this course was the most favourable, for if the mole had been allowed to continue its interstitial destruction of the uterus, nothing short of total extirpation of the organ would have saved the patient.

MULTIPLE DIVERTICULA.

Honl demonstrated two cases of multiple diverticula of the small intestine. In the first case there were thirty-nine of these diverticulæ present, and in the second eighty-seven. The wall of each of these was composed of the usual intestinal coverings.

The Operating Theatres.

NORTH-WEST LONDON HOSPITAL.

ENLARGED SPLEEN IN FRONT OF RIGHT KIDNEY SIMULATING RENAL TUMOUR.—Mr. MAYO COLLIER operated on a woman, *æt.* 48, who had for the last six months complained of pain and discomfort in the right lumbar region. There was no history of having passed a renal calculus or renal colic. No jaundice or history of biliary colic. The patient had never been severely injured or subjected to a blow on the part. The lungs were apparently free from tubercle. There had never been blood or matter in the urine as far as the patient knew. She was the mother of several healthy children, and had not had difficult times during child-birth. The digestion was indifferent and the colour of the patient indicated that something was wrong with her nutrition. The condition of the abdomen when first seen precluded any possibility of making out the state of its contents, it was so extremely rigid, Mr. Mayo Collier subsequently examined the patient under an anæsthetic and could make out what appeared to be a large ovoid tumour in the right renal region, extending from below the liver to the iliac fossa. On bimanual examination, a feeling of fluctuation was very apparent. The left lumbar region was apparently quite free from anything abnormal, and the whole left half of the abdomen was found to contain no indication of anything unusual. Mr. Collier, with those around who examined the case whilst under the anæsthetic, came to the conclusion that this was probably a hydronephrosis or possibly a large tuberculous kidney, and determined on an early operation. Mr. Collier said if it turned out to be a large tuberculous kidney the incision as for lumbar nephrectomy would have to be combined with the abdominal incision, as the tumour would be too large to remove through the loin. If the case were a hydronephrosis or pyonephrosis, the lumbar incision for the present would serve. Mr. Collier made an incision midway between the last rib and the crest of the ileum, extending from the outer border of the erector spinæ downwards and outwards for about four and a half inches. On reaching the perinephritic fat the kidney could be felt apparently quite healthy, but in front of this was a hard, elastic mass with a free straight edge, movable, and not adherent to the kidney. In order to further elucidate the nature of the mass the peritoneum was incised and the tumour partly withdrawn from the wound. It was without doubt an enlarged spleen that extended from below the liver on the right side to the right iliac fossa. It did not extend to the left beyond the middle line. Its exact attachments above were difficult or impossible to make out from the number of adhesions to adjacent omentum and other organs. It having been decided not to proceed further, the abdomen was closed in the usual way and if the permission of the patient were obtained the mass could be removed subsequently by a median incision.

BECKENHAM COTTAGE HOSPITAL.

NEW METHOD OF DEALING WITH HÆMORRHAGE FROM THE STOMACH WHEN NO BLEEDING POINT CAN BE FOUND.—Mr. ARBUTHNOT LANE operated on a patient who had been admitted into the hospital under the care of Dr. Randall suffering from most profuse hæmorrhage from the stomach. He was practically in a dying condition, and it was obvious that the loss of

even a small additional quantity must of necessity prove fatal. Indeed, it seemed as if he would die on the table. The stomach was exposed and examined digitally throughout. It was then opened up along its anterior surface by a transverse incision and its mucous lining was gone over carefully. As in similar cases Mr. Lane had operated on previously, no bleeding point or abrasion could be discovered. He sewed up the incision in the wall and then proceeded to put ligatures around the gastric, pyloric, and right gastro-epiploic arteries, including a few veins which were in immediate contact with them. The wound in the abdominal wall was then closed. Mr. Lane said he had never previously attempted such an extensive ligaturing of vessels as in this case in which the stomach was left to depend for its blood supply on the left gastro-epiploic artery, nor had he heard of its having been adopted. The progress of the patient was most satisfactory, there being no recurrence of the hæmorrhage.

WEDNESDAY, FEBRUARY 8, 1905.

THE SUNDAY AND KING EDWARD'S FUND —THE SPECIAL HOSPITALS AND AMALGAMATION.

THE more one inquires into the grants of the Metropolitan Sunday and the King Edward's Hospital Funds, the deeper grows the mystery. In previous articles of the present series it has been shown how certain hospitals receive regular awards, while others of apparently equal standing and possessing equal claims are sent empty away to labour under the unmerited slur of being ignored by the Funds in question. In this way two ancient and honourable institutions, the City Orthopædic and the Western Skin Hospitals, with a long and absolutely untarnished history, have been refused grants. In the case of the City Orthopædic, the reason given is that it refuses to amalgamate with the National Orthopædic. The City Orthopædic naturally objects to sell its freehold site and become swallowed up by the National, however much the Chairman of that institution may wish to swell the coffers of that charity, as he has already done by the purchase-money arising from the sale of the Royal Orthopædic

Hospital, a transaction that from a business point of view we regard as a scandal and a disaster. The Chairman of the National, (a) Mr. J. R. Cooper, we understand, is in a position to urge his views on the Sunday Fund, inasmuch as he occupies a position on the Council of that body. There is not the slightest evidence that he has ever used his influence with the Fund in order to secure any advantages accruing to the particular hospital of which he is chairman from the accumulation and absorption of other institutions. At the same time we think his dual capacity unfortunate in view of the serious and unanswered criticisms that have been laid for several years before the public by the Governors of the Royal, who opposed the sale of the site and were supported by the *Lancet* and by THE MEDICAL PRESS AND CIRCULAR. There are two members of the Council and of the Distribution Committee of the Sunday Fund, who act as its Honorary Secretaries, namely, Mr. Martin, of the St. Mark's Hospital for Fistula, and Mr. Gilliatt, of the Royal Chest Hospital. Again we think the dual position unfortunate. Both the hospitals named represent specialties that are, in the view of most medical men, superfluous and unnecessary. Both of them, however, receive liberal grants. We have not heard, moreover, of any pressure having been brought upon Mr. Gilliatt to amalgamate his chest hospital with one of the other special institutions of the kind in London. Why should the Funds fix on orthopædic hospitals to carry out their policy of amalgamation, regardless of the exchange of good freehold endowment for terminable bricks and mortar, and for the unjust dismissal of surgeons holding Scotch qualifications and other little items of injustice or disaster that may be entailed by amalgamation? There are many eye hospitals in London—why should they not amalgamate? So far from suggesting that, both the Funds we are criticising pour huge sums of money yearly into the coffers of the Royal City Ophthalmic Hospital (formerly Moorfields), which has been rendered bankrupt by the sale of an enormously valuable city site and its removal to another district. Why should the money of the public be bestowed upon this foolish virgin? The process is like pouring water into a sieve. If amalgamation were wanted anywhere, surely the Funds should begin with the City Ophthalmic. It is quite true, as pointed out by Sir Henry Burdett, that the King's Fund was not in existence when the Moorfields site was sold. The King's Fund, nevertheless, is helping the hospital to keep its head above water by grants that seem to us to be economically indefensible. From a consideration of the facts of the small hospitals that receive or do not receive grants from the Hospital Sunday and the King Edward's Funds, it is impossible to arrive at any general principles. Neither bankruptcy nor financial stability, neither a long and untarnished history nor years of un-

answered exposure in the columns of *Truth*, neither unceasing economy nor reckless extravagance, neither the desirability nor the superfluity of the particular kind of practice dealt with, none of these things appear to move the Funds one way or the other. The word has apparently gone round that orthopædic hospitals must amalgamate, that skin hospitals must be banned (except St. John's, which is no longer a hospital, but a limited company), that the Royal London Ophthalmic must be kept going at all costs, that certain specialties such as fistula and chest diseases deserve powerful support. It seems clear, moreover, although we have not enough facts to arrive at a firm conclusion, that one not unfavourable condition as affecting grants is to have friends at court; otherwise, on the Councils of the two Funds. In fact, it is to the non-representative nature of the Councils of the two Funds that much of the chaos to which it has been our duty to draw attention may be traced. We would respectfully urge that view both upon his Majesty the King and upon the Prince of Wales, who have hitherto shown a wise interest and wisdom in the guidance of the two great distributing charitable agencies with which they are so closely identified. The defects we have indicated are perhaps not in themselves of great magnitude, but they are none the less real to many persons whose interests, professional and otherwise, are involved. We suggest that the constitution of both the King Edward and the Hospital Sunday Funds would be greatly broadened and strengthened by the inclusion in future of representatives of the smaller hospitals, and by the publication of reasons for the withholding of grants from particular hospitals.

ARTERIO-SCLEROSIS.

No single condition in medicine is perhaps of greater moment than arterio-sclerosis, and yet so insidious is its onset and so indefinite are its early symptoms that it attracts far less attention to its study than its importance deserves. The subject formed the topic of some interesting papers at the Congress of Internal Medicine at Leipsic last year, and it was handled from different standpoints by several observers working in different fields of medicine. The old saying that a man is as old as his arteries was never truer than it is to-day. The conditions under which civilised man at present lives conduce not a little to early degenerations from fatigue and chronic intoxications. The wide-reaching significance of arterio-sclerosis was brought out by Bahrdt upon a study of the mortality-experience of life insurances, a study which led him to the conclusion that this condition, or its complications, caused the death of 22 per cent. of the insured. This heavy mortality-figure contrasts strikingly with a death-rate for the same offices of 7 per cent. from tuberculosis. Now, all life-assuring corporations are wide awake to the danger of tuberculosis as a cause of death, but arterio-

(a) By an inadvertence in our last issue the name of the chairman of the Amalgamated Orthopædic Hospital was given as Mr. Martin instead of Mr. Cooper.

sclerosis, probably because its mortality falls at a late period of existence and is generally returned under some other heading, is almost ignored. The diagnosis of early arterio-sclerosis is attended by the greatest difficulty, and much work is needed to elucidate the clinical symptoms that indicate its onset. Fortunately, instruments for measuring the calibre of the arteries and for estimating the height of the blood-pressure in them are becoming more trustworthy, though they have hardly yet attained a degree of exactitude that warrants their general application by those who are not fully accustomed to their complexities or vagaries, and it is only by studies on actual patients extending over many years, accompanied by observations by such instruments, that helpful information is to be obtained. The first symptoms apparent will probably be a distinct and constant rise in blood-pressure, a rise which may be due either to some thickening and want of elasticity in the vessel-walls, or to the operation of some general cause which, if continued long enough, would lead to such thickening. The *role* that mere increase in blood-pressure, apart from any other condition, plays in the etiology of arterio-sclerosis was shown by some experiments made by Erb, junior, and related at the same Congress. Erb injected daily into the vein of a rabbit's ear three drops of a 1-1,000 solution of adrenalin, and after six weeks of this treatment he found that the arteries showed diffused nodular thickening with calcification. Another animal, similarly treated for two months, showed even more striking vascular changes, namely, aneurysmal dilatation of the aorta and an apoplectic focus in the brain, together with general thickening of the arteries. Although no fatty degeneration was found in this case there was some calcification of the arteries and proliferation of the inner coat. Without holding these experiments to be conclusive, it may safely be said that they are highly suggestive of what may be termed a mechanical origin for arterio-sclerosis, in some cases at any rate, and thus it may be that a set of circumstances that throws a prolonged strain on the tissues and necessitates the maintainance of the blood-pressure at a high level for some time may, in the end, be found to have led to a permanent increase in the blood-pressure from the establishment of chronic arterio-sclerosis. This is all the more likely to be the case when the general nutrition is gravely affected by mal-nutrition or toxic influences, or when there is hereditary predisposition to early degenerative processes. The over-distension of the elastic and musculo-elastic coats of the arteries leads to a gradual replacement of the elastic layers by more lowly organised tissue, a change that is accompanied by compensatory hypertrophy of the other coats, and leads to diffuse or nodular thickening of the walls of the arteries. Atheroma, calcification and aneurysmal bulgings follow. Once established, arterio-sclerosis has effects of far-reaching

importance on every organ, due to chronic insufficiency of their blood supply, and these effects on the heart itself, through the calcification of the coronary arteries, on the brain and cord, on the kidney and other tissues, are well known. The treatment of arterio-sclerosis in its early stages was dealt with by Romberg and Gröbel, and they both agreed that though no drug known could alter anatomical lesions in the arteries, the iodides in small doses and the nitrates are useful in lowering general blood-pressure, and they also concurred as to the benefit derivable from carbonated baths and exercises. After removing the causes that had led to the initiation of the condition, such as alcohol, over-work and continued excitement, much benefit may be gained and life may be prolonged by judicious change of climate, rest, and much sleep. The bowels should receive special attention, and a good daily evacuation ensured, whilst a simple diet, rich in vegetables, is best. There is no doubt that arterio-sclerosis is a condition at once complex and little understood, and there is equally little doubt about its immense importance in view of modern conditions of urban existence. We should like to see more attention paid to its early recognition and treatment, for, once well established, nothing can prevent gradual decay and disintegration of the whole organism.

Notes on Current Topics.

New Navy Medical Regulations.

WE understand from semi-official sources that most important new regulations will shortly come into force with regard to the Navy Medical Department. The existing competitive system, if our information be correct, will be forthwith abandoned. In future, civilians with medical qualifications will be invited to take service for a short term of years. Pay is foreshadowed at the not illiberal rate of £1 per day, with, it is to be presumed, an extra grant for uniform. On retiring after a longer period than five years a gratuity of £500 will be awarded. By this means the Admiralty hope to secure a stage procession of surgeons who have not fallen into the almost inevitable rut of professional lethargy engendered by a prolonged experience of routine medical life at sea. On the other hand, they can hardly expect to command the services of highly skilled and experienced men at the rates of pay mentioned. Conversely, the five or six years' life at sea would be likely to injure the prospects of the young civilian surgeon to no small degree. At the outset of his career every day has an incalculable educational value to the embryo practitioner. A single voyage is often of value to the young qualified man, as it enables him to rest after the severe brain-fag entailed by passing his examinations, and at the same time enables him to see something of the world. A longer experience of the sea, however, is a snare and a delusion, so far as the formation of sound habits of professional study and observation are concerned.

Mr. Troutbeck's Mandate.

THE Westminster Coroner, Mr. Troutbeck, seems determined to "run amuck" among the medical practitioners of his district. On such an occasion as the death of an infant through overlaying he is not content to accept the evidence of the ordinary medical practitioner, but his thirst for scientific enlightenment compels him to call in Dr. Freyberger, the so-called County Council pathologist, to inform the Coroner and his jury with more precise, exact, and absolutely superfluous detail what was the state of the body of the suffocated child. Surely the point is the suffocation, which could be testified to by non-medical evidence and by the skilled testimony of the nearest medical man founded on external inspection of the body. Then Mr. Troutbeck, called upon to examine into the cause of death of a child who died under an operation for cleft palate, called in his faithful henchman, Dr. Freyberger, although what light the latter could throw on the case of more value than that obtainable from a house surgeon one cannot divine. The ratepayers have to pay an extra two-guinea fee—we understand that is the scale of pay—every time Dr. Freyberger appears on the scene. That is a matter, however, for the ratepayers to settle with Mr. Troutbeck. Truth to say, signs are not wanting that some of those concerned are getting a little restless under Mr. Troutbeck's autocratic and costly *regime*. A few weeks ago, Dr. Freyberger was called to give evidence in another overlaying case. One of the jury asked why that second opinion was necessary. Mr. Troutbeck is said to have made the feebly forcible reply, "Because I choose." The foreman of the jury, however, drove his bolt home by the following sentence addressed to the Coroner: "No doubt some cases you have to deal with require special skill, but this was a perfectly straightforward case, and in this, as in other cases, I think the doctors who devote their lives to the service of the people should be called." The attention of the Lord Chancellor should be drawn once again to the mediæval methods of the Coroner for Westminster. His high-handed action is becoming a public scandal.

The Increase of Insanity.

AN intelligent and well-instructed article on the increase of insanity appears in the *Westminster Review* from the pen of Mr. W. J. Corbet, for many years member of Parliament for Wicklow. He sets himself to combat the comfortable doctrine held by the Lunacy Commissioners of Great Britain and Ireland that there is only an apparent increase of lunacy in the Kingdom. We have ourselves criticised the doctrine at various times, and shown that while the apparent increase is greater than the real increase, it is only the policy of the traditional ostrich that forbids the recognition of the latter. Mr. Corbet points out that no talk of proportional increase of population or of more accurate enumeration of lunatics is

sufficient to account for the fact that during the past forty years the count of lunatics in the Kingdom has increased nearly threefold. If one takes the case of Ireland, one finds that the number of insane persons in 1862 was counted as 8,055, in 1903 it was 22,794. Yet during that time the population fell from five and three-quarter millions to less than four and a half. Nevertheless, the Lunacy Commissioners who are appointed by the nation for the special purpose of furnishing expert advice on matters relating to insanity deny that there is any problem to be solved. Mr. Corbet goes on to criticise the lack of progress in our dealings with insanity. "Measures for the prevention or alleviation of all manner of bodily diseases, from bubonic plague to phthisis and variola, constantly engage the attention of eminent scientists. The discovery of means to overcome or mitigate the fogs of London have quite recently been under discussion. Surely such matters are less important than the safeguarding of the sane from the contamination of the taint of insanity by inheritance." It is true that as yet we only touch the fringe of this great problem.

Recent Criticisms of Bart.'s.

EVER since the authorities controlling the ancient and noble charity of St. Bartholomew's decided to rebuild their hospital, they have been in hot water, and they must look back with regret to the piping times when they used to administer its vast resources secure from the breath of criticism. The re-building scheme, with its gigantic expenditure of money, has several times been the subject of articles in the pages of this journal, and we still adhere to our opinion that the wrong course was decided upon. Nor do we think that the attitude taken by the governing body has been free from blame; they have shown throughout their transactions a certain resentment at their policy being impugned by outsiders, and they are reaping the consequences in the shape of a pitifully feeble response to their appeal for funds. In Mr. Andrew Motion, chairman of the Cannon Brewery Company, has arisen a forcible critic from the Governors' own ranks, and he has taken them pretty severely to task on matters of internal administration. Mr. Motion promised, on behalf of the Cannon Brewery, a sum of £1,000 for every £100,000 that was raised toward the £500,000 required for the fund for re-building and carrying out the various alterations now on foot with regard to the charity, and he seems to have assumed that the company in due course would have become entitled to nominate a Governor for each £50 they subscribed. The Governors were glad enough of the cheques—of which only one has so far been paid, as the first £100,000 has not yet been subscribed—but they were rather taken aback by his expectation that the brewery company should nominate Governors, for, as they point out in their reply, this would give Mr. Motion substantial support in the management of affairs. It would seem

to the outsider a simple matter of tit-for-tat that a large subscriber should wish for proportionate representation in the administration of the money he subscribed, but to the Governors the idea seems a novel one, and therefore worthy of opposition. Mr. Motion referred to the large sum, £900 a year, that the Governors propose to pay their retiring clerk as a pension, and also to the fact that the son of this officer has been put into a position carrying with it a salary of £400 a year. The pension strikes one certainly as not erring on the side of niggardliness, and doubtless the Governors thought Mr. Cross' son capable of carrying out the work of his office; we are glad to see that they are prepared to defend their action in both instances. Many medical men who are giving a great deal of their time and energies to the hospital must, we should think, be rather sorry that they are not clerks; snug pensions of £900 must make their mouths water. At any rate, this sum formed the culminating point of the ambitions of Dr. Pangloss.

The Farnborough Libel Action.

THE slander and libel action which was tried last week in the King's Bench Division must have caused keen regret to all medical men. The action was brought by Mr. J. H. Peet, a practitioner at Farnborough, against Mr. T. G. Lithgow, of the same place, for certain defamatory statements the latter was said to have made with regard to Mr. Peet's conduct. Mr. Lithgow, in his capacity of Poor-law Medical Officer, was attending an old man who was very ill, and after performing a slight operation for his relief, he seems to have concluded that it was inadvisable to repeat it on account of the grave state of the general health. The Vicar of the parish, on a parochial visit, finding the man in much suffering, took the unusual course of consulting his own doctor, Mr. Peet, and sending him without Dr. Lithgow's knowledge to see the patient medically. Mr. Peet decided on his own account to perform the operation again, and a little later he did the same once more. On both occasions when the operation was performed the patient is said to have suffered much pain. Shortly afterwards the man died, and Mr. Lithgow was applied to for a certificate, and he then learned for the first time that Mr. Peet had been attending. Mr. Lithgow, after interviewing Mr. Peet and the Vicar, wrote a letter to the *Guardians*, couched in strong terms, animadverting on the conduct of Mr. Peet and the Vicar, and it was this letter that formed the subject of the action. The jury eventually decided that the libel had been substantiated, in spite of the privilege which has generally been held to attach to reports made by officers to their Boards, and Mr. Peet was awarded £50 damages. It is a painful matter at the best of times to see two members of a learned and charitable profession fighting out their differences in a public court, and one could wish that this matter had been settled before the

trial came on. It is needless to say what opinion medical men are likely to hold with regard to a *confre* who attends a patient without the knowledge and consent of the patient's own medical man, and almost equally needless to say that an ordinary court cannot be made to see the matter in the same light. That Mr. Lithgow acted unwisely in letting his indignation carry him to the point it did is obvious from the verdict, but it is not surprising that he should have been angry when the truth came to his ears. There are, we fear, few, if any, medical men who have not suffered at one time or another from the ill-directed zeal of ministers of religion.

Peculiar People.

IT is so long now since we came across the report of an inquest on the child of any of the "Peculiar People" that we had begun to think that the members of that sect—which perhaps of all others best justifies its title—had all availed themselves of the special dispensation granted by their elders allowing them to call in a doctor when their relatives were ill. However, we were mistaken, as we see that an inquest has just been held at West Ham on a child named Chignell, who died without benefit of doctors. As the cause of death was ascertained at the *post-mortem* to be tuberculous meningitis, the surgeon called at the inquest was unable to say positively that medical skill or attention could have relieved the patient, and as there was no other evidence of neglect, a verdict of "death from natural causes" was returned. The jury added their opinion that the parents should be cautioned, but the Coroner replied that he did not think it was much good doing so, as he had warned them so often before without result. The poor child had received the visits of elders on three occasions, and the usual anointing ceremony had been enacted, with much the same effect as these visits might be supposed to have. To argue or seek to convince these simple-minded folk of the folly of their ways would be to waste as much time as to argue with anti-vaccinationists on the protective value of vaccination. The relentless logic of facts stirs them as little as an earthquake in the Antipodes. Their attitude of mind reminds us forcibly of Huxley's old lady, to whom he had pointed out the error of Ussher's chronology, when viewed in the light of palæontological remains, and from whom he could only elicit the argument that fossils must by some Providential interposition have been put into the earth "to try our faith." The faith of the Peculiar People is as irreproachable as their integrity; it is only regrettable that it should conflict with the welfare of their offspring.

Erythema Infectiosum.

UNDER the above title a new symptom-complex was described by Stricker, of Giessen, and Escherich, of Graz, in 1899. Both of these observers claimed that it was a separate disease from

rötheln. The erythemata, as a class, are difficult to arrange in anything like scientific order, since the pathology of the different groups varies so widely. A great stir was made when Dukes described his "Fourth Disease" in 1900, but Ker, of Edinburgh, did not consider that the new affection answered the requirements of a malady liable to be confounded with rubella. The transient character of many erythematous eruptions often renders their diagnosis difficult or impossible, and when they are seen by artificial light they are notoriously deceptive. Dr. H. L. Keith Shaw, (a) of Albany, summarises the literature upon the subject and gives at the same time a good clinical account of the malady. It is a feebly contagious disease, occurring chiefly among children between the ages of four and twelve years. It is more prevalent in the spring and summer months. There appears to be an incubation-period of from six to fourteen days, at the end of which the characteristic maculo-papular, rose-red eruption shows itself upon the face. It is most pronounced upon the cheeks, the legs, and the outer surfaces of the arms. The rash fades upon pressure, and resembles both erysipelas and measles, but the subjective symptoms are extremely slight, there being no coryza nor desquamation. The glands are not enlarged, and there is no sore throat nor any elevation of temperature to speak of. The urine is normal throughout, and Koplik's spots are absent. The disease occurs in epidemics. Dr. Shaw suggests the term "erythema infectiosum morbilliforme," but he strongly repudiates the idea that it is an abortive form of measles. The absence of glandular enlargement and the intensification of the rash distinguish this complaint from rötheln.

Pulmonary Congestion and Sudden Death.

ATTENTION has been drawn from time to time to the occurrence of sudden death in patients whose bodies, *post-mortem*, show no definite lesion other than marked congestion of the lungs. Though some writers of authority, such as Brouardel, are sceptical in assigning congestion as the cause of death in such cases, yet as the number of these cases is multiplying it seems fair to regard it as the cause unless some more important lesion is discovered. Dr. Mince, who has recently published three cases of sudden death apparently due to congestion of the lungs (b) draws attention to a similar event as occurring in horses and other animals. In horses, fatal congestion, due in most cases to overdriving, is often accompanied by capillary hæmorrhage, and is then known as "pulmonary apoplexy." In other respects it presents marked resemblance to the appearance of the human lung after sudden death of this sort. It can hardly be said that the pathology of the condition is very clear, but it is to be hoped that all who have the opportunity of examining the body after sudden death of obscure origin will pay particular attention to the condition of the lungs.

Liability for a Nurse's Negligence.

OUR readers will remember the action for negligence taken against a London surgeon last year on account of the accident of leaving a foreign body in an operation wound. A somewhat similar case has just occurred in Canada, and as the points involved are not peculiar to Canadian law, it is worthy of mention. An operation for strangulated hernia was about to be performed by Dr. Bence, who brought with him a rubber water-bag for the operation-table. This he handed to the nurse, directing her to fill it "like an ordinary hot-water bottle." She, misinterpreting his instructions, filled it with boiling water, whereby the patient suffered painful but not severe burns. The nurse had not been employed by the operator, but by the ordinary attending physician of the patient. An action for damages by negligence followed. The judgment given decided that Dr. Bence was justified in expecting that a nurse would understand the filling of a hot-water pad, and that it was not his duty to supervise such details of the nurse's work. There had been, in consequence, no negligence on the part of the defendant. It is of interest that the case was decided by a judge sitting alone; if it had been tried by a jury it is not unlikely that the result would have been different.

Wounds in the Russian Army.

As all surgeons who served in South Africa are aware, the experience in that war has made a revolution in the treatment of bullet wounds. At the beginning of that war it was the custom to treat perforating wounds as if they were septic, and to operate in nearly every case, but a short experience showed that those cases did best which were left alone, and, on the whole, the mortality of bullet wounds proved unexpectedly low. From a letter of Professor von Manteuffel, who was attached to General Kuropatkin's army, it will be found that a similar state of things is observed among the wounded Russians in the Far East. The Japanese use a bullet of unusually small bore, which produces wounds of but little gravity. Perforating wounds of the abdomen, thorax, and cranium in most cases heal readily, unless where immediately fatal. Indeed, very often the bullet has but little "stopping power." It was not uncommon to apply a bit of plaster to a perforating wound before and behind, and allow the wounded man to continue on duty. Officers, too, continued to command, after suffering bullet wounds in the leg, abdomen, thorax or neck. The lack of "stopping power" of the Japanese bullets is to be attributed not only to their small size, but to their extreme hardness, which prevents "spreading." Professor von Manteuffel mentions an interesting point with regard to the shells in common use by the Japanese. They are filled with an explosive of such high power that when they explode they are reduced to fragments of mere powder, and are therefore comparatively harmless. In fact, the only

(a) *Amer. Journ. Med. Sci.*, January, 1905.

(b) *Boston Med. and Surg. Journ.*, December 22nd, 1904.

injuries from such explosions are rupture of the tympanic membrane and irritation of the mucous membrane of the nose.

Going the Round.

THE sincerest form of flattery is reputed to be imitation, but in all humility we would venture to suggest that an even more hearty compliment is transcription. This compliment is daily paid by one journal to another, and we are always duly grateful when each week we see the opinions and *obiter dicta* of the MEDICAL PRESS AND CIRCULAR transcribed and acknowledged by contemporaries in this country and America. To some journals, however, apt transcription's artful aid would seem to be the very breath of their nostrils, and we are amused at times to see the ingenuity that is exercised in the gentle art of dressing and pruning to fit the expressions of one journal for the consumption of the *clientele* of another. Amusement, too, may be gained by trying to pursue an article from one paper to another, and in tracking it to its source. We have been much puzzled of late to trace the origin of an article entitled "Some of Mr. Jonathan Hutchinson's Opinions." The bashful originator of this modest little production has evidently spent a profitable half hour with "Archives of Surgery," and extracted therefrom some of Mr. Hutchinson's ideas with regard to syphilis, leprosy, and skin diseases. Whether it be a tribute to the writer's gift of literary expression or to the renown of Mr. Hutchinson's name it might be invidious to inquire, but already this article has appeared in the *Pacific Medical Journal*, the *Journal of the American Medical Association*, the *Berlin klinische Wochenschrift*, and a medical publication in this country which finds its way unasked to the breakfast-table of most medical men in the Metropolis. This is as far as we have been able to trace it, but there may be yet other journals that have availed themselves of its services. It would be interesting to find the originator of this popular production. If he can write so well as to achieve quotation over half a hemisphere, he should have a brilliant literary career before him.

The Harmless, Necessary Bacillus.

A GOOD deal of entertainment was afforded to the officials and the public at the Southwark Police Court the other day by the hearing of an application by the Sanitary Inspector of Bermondsey for an order to destroy sixty tons of coffee, part of the cargo of a vessel which had been submerged in the Thames. The coffee was said to be "wet and moist and sodden," and one is somewhat surprised, therefore, that it should have formed part of the property of the Desiccated Grains Company; however, the latter fought the case to a successful issue, and as a sum of £50,000 was involved, it is not unnatural that they should have done their best. The prosecution called expert witnesses to show that

the coffee, after its sojourn in its watery grave, was permeated by *bacillus coli communis*, and that it was therefore unfit for use as human food. The defence admitted the presence of the bacillus, but contended that the organisms would all be killed in the process of roasting, a position that the sanitary authorities would not allow, as they held that even if the bacilli were all killed the products of their activity might still remain, and cause gastro-intestinal disturbance in the consumers of the coffee. Mr. Chapman, the magistrate, pursued the Solomon-like course of having a cup of coffee prepared from the impugned berries, and declared it looked and smelt like good coffee. He appears not to have ventured on tasting it. The defendants, however, produced a trump card in the shape of a medical man, who had had the courage of his opinions, and had drunk some of the coffee for two days beforehand without suffering any ill-effect. Mr. Chapman eventually decided that the evidence was not sufficient to enable him to order the destruction of the coffee—a decision which we think will be concurred in by most medical men reading the evidence. It is unfortunate that science is not able to speak unequivocally on these matters yet, but while bacteriology is in its infancy it is dangerous for its exponents to go into court and make dogmatic statements. The practical experiment of drinking the coffee would carry far more weight than any number of scientific theories.

The Pulse-Rate after Counting Aloud.

OF all the vital functions, that of the heart is most easily influenced by external conditions. The control exercised upon the circulation by the vaso-motor nerves is not always absolute, but is itself liable to be upset by the same causes. Variations in the rate of the heart-beat are continually being produced in accordance with the physiological need of an organ or tissue, but an increased frequency of the cardiac contractions is quite as often caused by psychic factors. Some years ago Professor Bernheim, of Nancy, observed that if the pulse-rate be taken while an individual is counting in a loud voice more quickly than the pulse, the speed of the latter is itself accelerated. In other words, the pulse tends to follow the counting. The difficulties of estimating the correct rate of the pulse while a person is counting loudly at a slightly higher speed are considerable, for there is an irresistible tendency on the part of the observer to count the spoken words rather than the pulse-rate. It is practically impossible for the subject himself to count both. In a recent communication upon the subject, Professor Bernheim (a) states that this difficulty can be overcome by the use of a Marey's sphygmograph, to which a recording cylinder is connected, and he has reported a series of thirteen cases in which the pulse-tracings were taken in this manner, the time in seconds being marked

(a) *Revue de Médecine*, December 10th, 1904.

in the usual way. The results varied according to the degree of arterial tension present. Thus it was found that in cases of normal tension an average acceleration of 9.5 beats per minute was observed in the pulse-rate after counting quickly in a loud voice, whereas, if the arterial tension was at all increased, this acceleration only amounted to an average of 6 per minute. A further series of cases is also recorded in which the counting was performed at a lower rate than that of the pulse, and it was noticed that a corresponding retardation of the pulse-rate was produced. In some cases, the mere suggestion of acceleration was sufficient to cause a quickening of the pulse-rate.

The "Nineteenth Century and After"—on Appendicitis.

ALTHOUGH that most excellent and classic review "The Nineteenth Century and After" may justly claim to be an authority on literature, art, and the ethics and the philosophy of life generally, it is none the less apt to go sadly astray when dealing with medical matters. Surely the Editor has enough ground of his own to cover without wandering into half-explored medical country in his eager quest for copy. Take the case of appendicitis, concerning which an article appeared in the last number of the "Nineteenth" from the pen of a writer better known in homœopathic than in orthodox medical practice. With an abrupt directness worthy of a Royal Duke of Russian origin, he traces all appendicitis to three causes, namely, chill, hurried eating, and aperient mineral waters. Of these three so-called causes, it is hard to say which is the most unlikely and absurd. "Chill" is the time-worn refuge of the incompetent physician, the thin and threadbare cloak of mediæval ignorance; hurried eating, well, if that were a cause of appendicitis, three-quarters of our citizens and nine-tenths of our schoolboys would be attacked offhand; while as to aperient waters—well, more of that anon. The whole trend of modern medical opinion points to bacterial action as the cause—the chief, well-nigh sole and invariable cause—of appendicitis. The bacterial mischief, in nine cases out of ten, follows constipation. Yet the sapient writer of the "Nineteenth" article is ready to throw overboard aperients—the sheet anchor of practical physic, past, present, and future. Clearly, he can have had little experience of the unspeakable value of natural mineral water in the treatment of constipation. Nature is a good physician, but a glassful of Hungarian water is often a better. In spite of all our admiration for the "Nineteenth Century" we would prefer trusting to orthodox medical sources for information as to how to prevent appendicitis. The article quoted reads like an echo of the Middle Ages. There are plenty of medical journals in London willing and able to deal competently with such a topic as aperient waters and appendicitis. There is really no need to trouble Fleet Street in the matter.

PERSONAL.

PROF. GILBERT BARLING, M.B., F.R.C.S., Professor of Surgery in the University of Birmingham, has been appointed Dean of the Faculty of Medicine in succession to Dr. Bertram Windle.

THE British Child-Study Association will meet at the Parkes Museum, Margaret Street, W., on Thursday, February 9th, at 8 p.m., when Dr. G. Shuttleworth will read a paper on some physiological problems in education. Sir Frederick Treves will preside at one of the meetings during the session.

PROF. PERRONCITO, now Director of the Veterinary School and Professor of Parasitology in the University of Turin, who discovered the presence of ankylostoma duodenale in the small intestine of the miner, has been permitted on the twenty-fifth anniversary of his discovery with an honorary degree from the University of Manchester.

THE Milroy Lectures before the Royal College of Physicians of London in 1906 will be delivered by Dr. W. H. Hamer, Medical Officer (General Purposes) to the London County Council.

SURGEON-LIEUT.-COL. EDGAR FLINN, V.D., who has recently resigned his commission in the Army Medical Reserve and Volunteer Medical Staff, has been granted the honorary rank of Surgeon-Colonel, with permission to retain his rank and uniform. He is one of the Inspectors on the Local Government Board (Ireland).

DR. HENRY O'NEILL, who has been nominated as High Sheriff for Belfast, is a keen advocate of city hygiene and has visited foreign capitals for the purpose of studying sanitary reform.

COLONEL W. A. MAY, C.B., Principal Medical Officer in Egypt, has been selected to succeed Surgeon-General W. Donovan, C.B., as Principal Medical Officer, Salisbury Plain District.

SURGEON-GENERAL W. J. FAWCETT, M.B., C.B., Army Medical Staff, is appointed Deputy Director-General, vice Surgeon-General A. Keogh, M.D., C.B., appointed Director-General, January 20th.

DR. KEENE, Surgeon to the British Steamer Ajax, of Liverpool, has been presented by the Czar with a gold cigarette case in recognition of his services to the Russian officers and men who were wounded at the naval battle off Chemulpo in February of last year, when the *Variag* was sunk. Dr. Keene is a graduate of Dublin University.

THE Inaugural Dinner of the Association of Medical Diplomates of Scotland will take place at the Trocadero, London, on February 14th. Tickets can be obtained from the Hon. Secretary, Dr. David Walsh, 18A, Hanover Street, London, W.

DR. GEORGE CHARLTON, of Montreal, has been appointed by the Government of the North-West Territories of Canada to establish a bacteriological and pathological laboratory at the capital of the Territories, Regina.

ON the nomination of the Council of the Royal College of Physicians, London, Dr. Thomas Buzzard, Dr. Watt Black, Dr. Clifford Allbutt, and Dr. Hale White were elected Councillors in the room of Dr. Gee, Sir Thomas Stevenson, Dr. Champneys, and Dr. Sharkey, who retired by rotation, and Dr. Percy Smith and Dr. de Havilland Hall were elected a fifth Councillor for one year and a member of the Finance Committee respectively in the place of Sir Isambard Owen, who has resigned these offices.

Special Correspondence.

[FROM OUR OWN CORRESPONDENTS.]

SCOTLAND.

MILK SUPPLY.—An interesting table of the results of nearly 800 analyses of milk, representing the ordinary public supply in the eastern counties of Scotland, has just been published by Mr. G. D. Macdougall, F.I.C., City Analyst, Dundee. The average of the whole series gives 3.72 per cent. of fat and 8.81 per cent. of non-fatty solids. The highest figures were got in Earlsferry (Fife) with 4.20 fat and 9.09 solids; the lowest from Buckhaven, with 3.18 and 8.87, and Monkeithing, with 3.57 and 7.91 respectively. From data available, it is estimated that a difference of .1 per cent. in the amount of fat represents for each thousand inhabitants a money value of £8 per annum. Thus in Dundee the percentage of fat is approximately .45 per cent. below the average, representing a loss for the whole city of nearly £6,000 per annum.

SMALL-POX IN SCOTLAND.—The following was the number and distribution of cases of small-pox from January 16th to 31st, inclusive:—Haddington, 2; Lanark, 1; Flemingston, 1; West Marystone, 1; Airdrie, 1; Linlithgow, 1; Stirling, 1; Larbert, 4; Laurieston, 2; Stenhousemuir, 1; West Carron, 1; Falkirk, 5; Grangemonth, 1—22 in all. In the majority of these places no cases had been intimated in the month prior to the period of this report.

MORISON LECTURES.—The second course of these lectures on "Variation in its Relation to the Origin of Insanity and the Allied Neuroses," was delivered before the Royal College of Physicians by Dr. John Macpherson during the week ending February 4th. In the previous course various neuroses were dealt with, and now the lecturer dealt entirely with insanity. Insanity, as popularly understood, was not a simple disease but a complex of different affections, only related by the fact that they all had as a result or accompaniment a disturbance of normal mental processes. Pathology not being sufficiently advanced for the purpose, a clinical classification was the best to adopt, and etiological or symptomatological subdivisions could never be more than adjuncts to this. By far the most important of the main divisions into which insanity fell was the confusional or toxic group and the group of recurrent insanities. The type of the confusional group was the delirium of fever, the main symptoms being delirium, confusion, and stupor; the chief clinical forms were alcoholism, dementia præcox, and general paralysis. Their chief and only cause was poisoning by bacterial or metabolic toxins which destroyed the delicate cells of the brain cortex, and as in most cases this destruction was very rapid, the prospect of recovery was not good. About 40 per cent. of admissions to asylums belonged to the group. The presence of toxins in these cases might be inferred from the general course and pathological changes in these maladies; it was also recognisable clinically by the high blood pressure, pyrexia, and polymorphous leucocytosis. The lecturer showed by means of microscopic slides the intense destruction of the cortical cells in this form of insanity. The recurrent type of insanity presented a clinical picture entirely different from the confusional variety; there was no mental confusion, and the chance of recovery from any individual attack was good. There was, however, the unfortunate tendency to relapse, which was one of the points in which these resembled the neuroses. Neither mania, melancholia, nor paranoia ever resulted from an infection; to speak of delirium as mania because it was attended by excitement, or confusional insanity as melancholia because it was attended by depression, or to talk of typhoid causing melancholia, or alcoholism mania, was an error. Various slides were exhibited showing that the cortical cells remained intact after repeated attacks of recurrent insanity. Though insanity implied a susceptibility of the nervous system to yield to adverse influences, it was not wholly a disease of the brain, but the functions of many of the

body glands, as well as the immunity of the tissues in their resistance to invasion by toxins, had to be taken into account. It is an error to suppose that barbarous races have less insanity than civilised peoples; on the contrary, probably civilisation brings with it a tendency to decrease in insanity. The forms of insanity differ considerably according to the type of the race; thus Kraepelin's researches among the Javanese prove that among this people the prevalent type is an acute mania, of short duration, not unlike the Malayan lath. Similar forms occur among the Soudanese and the natives of Central Africa. A sharp distinction must be drawn between civilised communities which register their insane and those whose scientific appreciation of disease is so rudimentary that no provision of this kind is made. The amount of statistical insanity is therefore an index of their civilisation, and not of the relative amount of insanity. The statistics of insanity in Scotland fifty years ago were manifestly under-estimates of the amount of mental disease existing, and even now, with diminished prejudice and a much higher standard of diagnosis, it was impossible to estimate exactly the amount of mental unsoundness. Until such an estimate could be arrived at it was absurd to speak of insanity as increasing. The census returns for 1901 showed a much higher proportion of insane persons in the Northern and North-Western counties than in the Midland and Southern districts, and a similar difference exists between rural and urban districts. Grouping the populations of Argyll, Caithness, and Inverness on the one hand, and Glasgow, Edinburgh, and Dundee on the other, and correcting for age and sex distribution, it is found that in the former the proportion of pauper lunatics is 4.86 per thousand as against 3.06 in the cities named. Even in the counties themselves the same differences are found; parishes with industries, immigration, and an increasing population show a lower lunacy rate than those which are stagnating and have a dwindling population. The latter have an age distribution among their population peculiarly favourable to a high lunacy rate, the proportion of persons alive over fifty being higher than in the more prosperous parishes. It thus appears that a stagnant or dwindling population is at a disadvantage as regards statistical insanity—(1) because the age distribution of the population is abnormal; (2) because emigration removes chiefly strong, healthy adults, at an age at which they are not liable to insanity, and leaves behind the weak, diseased, and imbecile; (3) because, if insanity be present in such a depleted population, it tends to become inbred, there being no inducement for the return of young, healthy adults to introduce a new strain.

BELFAST.

PUBLIC HEALTH MATTERS.—The Belfast Corporation is showing some signs of interest in matters relating to public health, which it is earnestly to be hoped will continue. The medical officer of health has reported that a number of areas in the city are so bad as to be beyond the possibility of improvement, and the only thing to be done is to close the houses in these slums and destroy them. Of course, this fact has long been known to the public, but it is satisfactory to find it officially recognised. The matter has been referred to the surveyor and executive sanitary officer for further reports. Another thing which has long been known, but has only now been officially recognised, is that the expensive destructor erected some years ago is a failure, and, as one of the members of the Corporation said, might as well be pitched bodily into the Lagan. The reticence of the Public Health officials regarding the destructor has been mentioned in this column on several occasions, when the annual report of the Medical Officer of Health was under criticism. It appears that the affair has now stopped work, owing to some dispute between the Corporation and the contractor. During the five weeks ending last week, 210 cases of zymotic disease had been notified, including 60 scarlatina, 39 erysipelas, 36 typhoid, 28 simple continued fever, and 24 small-pox. One of these last cases proved fatal, the patient being a man who had never been vaccinated.

A scheme of prizes for house cleanliness has been submitted to the Public Health Committee, and has been approved by them. The competition is open to all occupiers of houses in Belfast at a rent of less than 4s. per week, and three prizes are offered entitling the winners to 52, 26, and 13 weeks' free occupation of their houses. The prizes will be awarded to those who keep their houses in the most sanitary condition from March to December of this year. The idea seems an excellent one, and it is to be hoped that the number of prizes will be largely increased.

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

CAUSES OF APPENDICITIS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The general reader would be glad to have some light thrown upon these frequent cases of appendicitis occurring now and then in all classes of society. We have not been furnished yet with a sketch of the physiological functions of the appendix vermiformis in the bodily economy, why it is an isolated tube, why it is attached always to the same place, and why its extremity is always loose. It has been surmised that appendicitis is connected with some errors of diet, but some hesitation may be felt to accept this in general as it arises in various classes of society under different regimens of food.

It is more probable that its cause lies in a similar category as those of hernia, and is more connected with perverted or misdirected muscular action of the body.

This idea may suggest attention to the abuse of cycling or motoring as a probable contributory cause, as the new disease seems contemporaneous with this modern form of locomotion. As the rolling and pitching of a ship in rough weather will bring on sea sickness by disturbing the natural pose of the bowels, so may the exercise of rapid cycling misdirect the localisation of the bowels, and cause motion to parts usually in a state of repose.

It would be of some interest, then, to direct inquiry to patients thus affected if they were in the habit of cycling or motoring frequently, and if the motion gave rise to any pain in the abdomen or disturbance of the functions of the bowels. I dare say a predisposition to hernia may be incompatible with horse exercise in the male, but the same cannot be alleged in the case of the female, as the seat on the saddle is flat, and puts no strain on the inguinal structures.

As appendicitis is a modern affection, so it may not be alleged that it is due to horse riding by either sex, a form of exercise of very ancient usage.

I am, Sir, yours truly,

W. V. BLACK, F.R.C.S.E.

Southport, February, 1905.

REVIVALISM AND MENTAL DISEASE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your issue of January 18th, you call attention to what I may be allowed to style an epidemic of religious excitement, and as there appears to be a desire on the part of well-meaning and disposed teachers of religion to encourage this ecstatic condition of mind, it becomes a question how far it may be considered conducive to the public health.

There can be no doubt, I submit, that a *mens sana in corpore sano* affords one of the best securities for social order and morality, and it is questionable whether violent efforts to arouse the public mind to steer in the path of rectitude, however well intended, will prove in the long run conducive to a robust state of health.

Now, Sir, although unanimity of opinion exists among the officials presiding over our asylums as to alcoholic excitement being a powerful factor as a cause of insanity, notwithstanding their statistics may be formulated on different methods of calculation, and

hence at variance, it is by no means obvious, at least to my way of thinking, after all said, taking into consideration the number of cases in our asylums suffering from religious delusions, and also the circumstance that so few drift in the path of religious excitement compared to the many who suffer from alcoholism, I say it is questionable whether religious fervour, if allowed to run to its height, would not be as powerful a factor in producing insanity as drink. However this may be, it is certain and obvious to any common observer, if he only review the development of the human mind throughout all ages and the consequences of religious excitement and fanaticism, culminating in religious wars and other excesses, that it is no groundless fear to suggest the policy of "moderation in all things."

I am, Sir, yours truly,

CLEMENT H. SERS,

Brighton, February 4th, 1905.

REVIVALLENZA.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Does it not rather look as if we are liable to epidemics of mental disorder, like those that disturb our health? It matters not what the religion of a country may be; all are liable to these disturbances.

The interesting question, of course, is, What is the cause of them? and as there is no doubt that they are evidence of a morbid mental state of a people, it might be well, as we have to deal with questions of insanity, if we gave some little attention to this recent malady—Revivalenza.

I am, Sir, your truly,

R. L.

MR. STEPHEN COLERIDGE AND THE HOSPITALS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Mr. Sydney Holland expresses a doubt that he ever taunted me with not being a subscriber to the London Hospital.

On January 20th, 1903, a letter of his appeared in the *Morning Post*, in which he said it was impertinent of me to want to see the accounts of the Medical College, and assigned as a reason that I was "not only not a subscriber to the hospital, &c., &c."

He asserts also that I have "preached to everyone: 'Don't subscribe to the London, don't subscribe to Guy's.'"

I should like to see any publication of mine justifying that assertion.

I am, Sir, yours truly,

STEPHEN COLERIDGE.

London, January 11th, 1905.

NATIONAL PHYSIQUE AND NATIONAL DEFENCE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—May I ask you to be good enough to allow me to draw the attention of your readers to an important address, on the "Physical Advantages of Universal Naval and Military Training," which was given by Lieut.-Colonel O. T. Duke, until lately Hon. Secretary of the Lads' Drill Association, at the Caxton Hall, Westminster, at 5.30 p.m. on Tuesday, February 7th, Sir William Church being in the Chair?

In urging the adoption of a moderate form of universal naval or military training for national defence, the National Service League looks to wider issues than those involved in questions of defence alone, important as they are. We believe that a truly national system of training, which would reach the boy at school and the youth as he attains manhood, could not fail to have a profound effect on the physical condition of the people, not only by the direct improvement involved, but by drawing the attention of the nation to the many causes which, in a highly industrial country like ours, are at work to undermine the health of the community.

The intimate relationship between the two great questions of national defence and national physique leads me to express the hope that many of your readers,

to whom one at least of these questions appeals in a special manner, will peruse Colonel Duke's lecture,

I remain, Sir, yours truly,

GEORGE F. SHEE,

Secretary, The National Service League,

Dacre House, Victoria Street, S.W.,

January 27th, 1905.

CENTRAL MIDWIVES BOARD.

Most of our readers will be interested in the scheme of examinations approved by the Privy Council, January 17th, 1905, and laid before the Board at their meeting on January 26th.

EXAMINATIONS.

(1) Every examination shall be partly oral and practical, and partly written, and shall be conducted by not fewer than two examiners. (2) The first examination shall be held in June, 1905. (3) Thereafter the examination shall be held three times a year, or oftener if necessary, in London and the Provinces, simultaneously, on the same papers. "The Board reserves to itself the right to appoint one or more qualified medical practitioners as visitors of the examinations, both London and provincial." (4) The first provincial centres shall be (a) Bristol, (b) Manchester, (c) Newcastle-on-Tyne.

EXAMINERS.

(1) A list of examiners, both for London and the provinces, shall be prepared by the Central Midwives Board from those who are willing to serve and act, when required, by the Board. This list shall be subject to annual revision by the Board. Before such a list is formed applications for the post of Examiner shall be invited by advertisement. (2) All examiners shall be men or women who are duly qualified medical practitioners. The examiners may, when they see fit, with the consent of the Board, employ for certain parts of the examinations properly qualified women who are not medical practitioners; their remuneration being provided out of the sums payable to the examiners for the conduct of examinations. (3) No examiner shall examine his own pupils. (4) A paper of directions to examiners shall be drawn up and issued to each examiner on his appointment. (5) The remuneration of an examiner shall be at the rate of seven shillings for each candidate examined, with a minimum fee of two guineas for each examination. (6) The examiners, both London and provincial, shall be invited to meet at the offices of the Central Midwives Board as often as may be necessary.

LONDON EXAMINERS.

(1) The arrangements for the London examinations shall be made by the Secretary of the Central Midwives Board, with such extra assistance as may be necessary. (2) The duties of the London examiners shall be: (a) To consider examination questions suggested by provincial examiners. (b) To set all the papers of examination questions both for London and the provinces. Two of the examiners, with the assistance of one of the medical members of the Central Midwives Board, to be appointed for the purpose, shall undertake this duty in rotation. The remuneration of the examiners in respect of this duty shall be two guineas each. (c) To conduct the examination, written and oral, of all candidates presenting themselves for examination in London. (d) To report to the Central Midwives Board the result of each examination held in London as soon after the examination as possible.

PROVINCIAL EXAMINERS.

(1) The examiners appointed by the Central Midwives Board to conduct the Board's examinations in a provincial centre shall assist the secretary of the Board in making the necessary arrangements for the examinations. (2) The duties of the examiners in each provincial centre shall be:—(a) To conduct the examination, written or oral, of all candidates presenting themselves for examination at the centre. (b) To report to the Central Midwives Board the result of each examination held at that centre, as soon after the examination as possible.

DIRECTIONS TO EXAMINERS.

(1) The paper shall consist of not fewer than six questions, and the time allowed for answering shall be three hours. (2) Notes should be taken, either by the examiner himself or by a colleague, of the subjects upon which the candidate is questioned in the oral examination. (3) Fifteen minutes should be considered an average period for the oral examination of each candidate. (4) Examiners should avoid questioning candidates as to where and by whom they were trained, so as to avoid any suspicion of bias.

INTERNATIONAL MEDICAL CONGRESS, LISBON, 1906.

A MEETING of the National Committee for Great Britain and Ireland of the Fifteenth International Congress, to be held at Lisbon April 19th to 26th, 1906, was held at the rooms of the Medical Society of London on February 3rd, 1905. There were present, among others, Dr. Pavy, F.R.S., President of the National Committee, Sir William S. Church, Bart., K.C.B., Sir Dyce Duckworth, M.D., Dr. Ferrier, F.R.S., and others; and the Hon. Secretaries, Dr. Clive Rivière and Mr. D'Arcy Power. It was announced that the following gentlemen had undertaken to act as "Rapporteurs" at the forthcoming Congress, as it was the wish of the Lisbon Committee to make the "Rapports" a special feature of the meeting. Dr. Stanley B. Atkinson, Hon. Sec. of the Medico-Legal Society and barrister at law, "Spontaneous and Criminal Abortion from its Medico-legal Aspect." Dr. Chalmers, Medical Officer of Health for the City of Glasgow, "The Administrative Control and the Technique of Public Disinfection." Mr. Treacher Collins, "Ocular Tuberculosis." Prof. Ferrier, "The Nature and Pathological Physiology of Tabes." Mr. Goadby, Lecturer on Bacteriology at the Dental Hospital, "The Treatment of Pyorrhœa Alveolaris." Dr. Gulland, "The Classification, Origin, and Probable Role of Leucocytes, Mastzellen and Plasma Cells." Sir Patrick Manson will open a discussion on Tropical Medicine. Dr. Mott, "Cerebral Lesions in Psychoses of Toxic Origin." Mr. D'Arcy Power, "Recent Advances in the Surgery of the Arteries and Veins." Dr. Still, "The Spastic Affections of Childhood, their Classification and Pathogeny." Dr. Sutherland, Deputy Commissioner in Lunacy for Scotland, "The Prophylaxis and Treatment of Habitual Criminals." Mr. C. E. West, Chief Assistant in the Aural Department at St. Bartholomew's Hospital, "Study of the Elephantine Action of Foreign Bodies in the Ear and of Post-Nasal Growths." The subjects for the "Rapports" were selected in every case by the Executive Committee at Lisbon.

A letter was read from Messrs. Cook, containing a proposition to charter a first-class passenger ship to convey visitors to and from Lisbon, calling at Oporto, Vigo, and Corunna, and acting as a floating hotel during the Congress week. The suggestion was approved by the Committee, but Messrs. Cook were desired to ascertain the exact position of the anchorage in the Tagus, that inquiries might be made locally as to its suitability, both from the point of view of the hygienic surroundings and of distance from the seat of the meetings of the Congress. Letters were read from Dr. Ogilvy Will and from Dr. J. F. Sutherland giving the results of certain inquiries which they had made in regard to the housing of those who did not wish to go by sea and remain on the boat. It appeared from these inquiries that rooms could now be obtained at a moderate price at Cintra, about 40 minutes by train from Lisbon. The hotel is well spoken of and the proprietor says that, at present, he has 16 bedrooms, most of which can be used by two persons. It appears imperative, therefore, that those who intend to go to the Congress and do not wish to depend on the efforts of the local Committee to obtain lodgings should at once take the opportunity of reserving rooms. Delay is likely to lead to the same disastrous consequences as at Madrid.

Obituary.

JOHN MARRIOTT, M.B.LOND.

WE regret to announce the death of Dr. John Marriott, at the age of forty-four, while on a visit to Harrogate. Deceased was to have been married last Wednesday to Miss Bertha Wilson, of Harehills, Leeds, but at midnight before the wedding day he was discovered lying unconscious underneath his bed-room window, and died soon afterwards. He had taken tickets from Leeds to London for himself and his prospective bride. Dr. Marriott was settled in practice at Northampton, and was at one time House Surgeon at Charing Cross Hospital. He graduated M.B. of London University in 1885 and M.R.C.S.E. in 1881.

GEOFFREY HETT, M.D.EDIN., M.R.C.S.ENG.

WE regret to announce the death of Dr. Geoffrey Hett, of 41, Westbourne Park Road, on January 25th, aged 61. Deceased was educated at Merchant Taylors School, then at King's College and the University of Edinburgh. After serving as house surgeon successively to the Lincoln dispensary and hospital, he settled in London and spent most of his life as a Bayswater practitioner. At one time he was honorary secretary of the Royal Medical Benevolent College. He was a busy worker in literature as well as in medical practice, and made numerous contributions to the *Saturday Review* and other journals. He was for very many years one of the honorary medical staff of the Westbourne Provident Dispensary. His death from heart failure will be felt by a large circle of friends.

New Appliances.

THE GLASEPTIC NEBULISER.

MESSRS. PARKE, DAVIS AND Co. have sent us a sample of a very workmanlike nebuliser suited for atomising fluids of any density. From a practical test we are enabled to say that it admirably fulfils the essential requirements of such an apparatus, which have been kept steadily in view by the makers. The points in question are that the working parts should be made entirely of glass, and thus be free from all possibility of oxidation or corrosion; that the instrument should be easily cleansed, and thus rendered perfectly aseptic; that it should be effective for nebulising or atomising liquids of practically any density or viscosity; that it should be capable of being used with a few drops of liquid; and, lastly, that it could be corded up to prevent evaporation or oxidation, or spilling of the liquid in the event of the apparatus being carried in the pocket. This little appliance is certainly one of the most perfect things of the kind that have hitherto come under our notice.

Medical News.

Influenza in Brussels.

THE special correspondent of the *Globe* reports that for the first time in the memory of Brussels opera-goers, the Monnaie was last night obliged to close its doors unexpectedly, owing to the illness of a number of its artistes. For some weeks the management of the opera has been fighting against the disabilities caused by the spread of influenza among the operatic staff, but, last night, the inevitable had to be conceded to on the principal tenor being struck down.

Centenary of the Royal Medical and Chirurgical Society.

It is announced that the centenary of the Royal Medical and Chirurgical Society will take place on May 22nd, 23rd, and 24th. There will be a reception by the President, together with an exhibition relating to medical matters of one hundred years ago, a festival dinner, and a *conversazione* at the Royal College of

Surgeons. It is expected that the exhibition will be of special interest, and any members of the profession or others who are able to lend anything of medical interest belonging to that period will be forwarding the success of the celebration. The exhibits will be strictly limited to what was in actual medical and surgical use in 1805; even medicine bottles, pharmaceutical apparatus, and old prescriptions of or about that date would find a place. The following distinguished scientific men have been nominated for the Honorary Fellowship of the Society:—Professor Nothnagel, of Vienna; Professor Welch, of Baltimore, Professor Marchiafava, of Rome; Dr. Ramon y Cajal, of Madrid; Professor Pavloff, of St. Petersburg; Professor Kitasato, of Tokio; Professor Bohr, of Copenhagen; Lord Rayleigh, Sir Samuel Wilks, Sir William Ramsay, Sir William Gairdner, Lord Lister, Dr. Gaskell, and Dr. Robert Barnes.

Medical Sickness and Accident Society.

THE usual monthly meeting of the Executive Committee of the Medical Sickness Annuity and Life Assurance Society was held on 27th ult. at 429, Strand, London, W.C. There were present Dr. de Havilland Hall, in the chair; Dr. G. A. Heron, Dr. J. Brindley James, Dr. M. Greenwood, Dr. J. W. Hirst, Dr. St. Clair B. Shadwell, Dr. Fred. S. Palmer, Dr. W. Knowsley Sibley, and Dr. J. B. Ball. The accounts presented showed that a considerable number of sickness claims arising from influenza had been received during the last few weeks, but they had for the most part been of short duration, and the list is now very little longer than is expected at this season of the year. The time of the committee was principally occupied in examining the special reports which in every January are furnished on what are called chronic cases. There are now nearly twenty-nine of these cases on the books and the reports received show that in all of them the members will probably draw their allowances, usually one hundred guineas a year, as long as their membership lasts. This practically permanent provision for those who can no longer work is considered one of the most important features of the Society's operations. Prospectuses and all other particulars, on application to Mr. F. Addiscott, Sec., Medical Sickness and Accident Society, 33, Chancery Lane, London, W.C.

Cure of Consumption.

SOME years ago the Poor-law authorities in Liverpool and district combined in the erection of a consumption sanatorium at Hesswall on the River Dee. At a meeting of the Liverpool Select Vestry on the 31st ult., a report was presented showing that the cost of maintaining the hospital was high and the results disappointing. Liverpool had ten beds in the hospital, and if they were occupied all the year round the cost would be £3 a week per patient, or a total of £1,560. In the two years' work of the hospital, of thirty-eight Liverpool patients discharged in three cases the disease was arrested, nine had died, sixteen had been re-admitted, two were in failing health outside, and eight had not reported. A member said that the Hesswall institution would soon be closed, and possibly that the building could be used for epileptics. Consideration of the recommendation was deferred.

THE Royal Maternity Charity of London, under the patronage of H.M. the Queen, has published its medical report for 1904. The total number of cases treated was 3,290, and there were 1,774 boys born as against 1,571 girls. The mortality was remarkably low, being only 1'51 per 1,000 in the case of the women, and 6'40 in the case of the children. The causes of death in the cases of the mothers were placenta prævia, pulmonary embolism, infective enteritis and collapse, enteric fever, exhaustion, following prolonged labour, in a poorly nourished patient.

Notices to Correspondents, Short Letters, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a distinctive *Signature or Initial*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in re-forwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

DIMINISHING BIRTH-RATE (Birmingham).—The correct name of the Society is The American Mother's Birth Insurance, Massachusetts, constituted for the purpose of paying a sick or disability benefit upon the birth of a living child.—Its Officers serve without compensation and it enables parents to provide in advance for a coming family.

SCOTCH DIPLOMATE.—We think you are wise in joining the A.M.D.S. Such medical societies constitute the chief element of strength in the organisation of the profession and are useful for the cultivation of fellowship, the exchange of professional experiences and acquiring much useful knowledge.

CIVITAS (K.S.).—We agree that the appointment of a Minister of Public Health is very desirable. In Belgium, Canada, and the U.S.A. the control of Public Health is vested in the Depts. of Agriculture and Navy, in France and Austria, in that of the Interior; in Germany in Police and Education, Sweden alone vesting it in a medical Council.

M.S.—The superheated air baths, followed by skilled massage ought to do good in the case you mention of muscular rheumatism in chronic Bright's Disease.

J. K. ROBERTSON.—Quite so, too strong a solution of perchloride of mercury may defeat its own object and set up an intense conjunctivitis neovascularium.

POST-MORTEM (Sunderland).—In the case of special liberties the appointment of Coroner is often made by the crown. In large towns the salary varies from £800 to £1,500 per annum. In all the cases it is usually small being calculated on the number of inquests held annually.

X. Y. Z.—Shingles may occur in chronic patients after arsenic, it is not necessarily always due to the drug, but may depend upon some trophic influence of the affected nervous system.

CLEAN SHAVEN MEN.

An ingenious advertisement has been issued by the proprietors of Wrigth's Coal Tar Soap in the shape of any person sending the nearest estimate of the number of clean shaven men there are in 10,000. It will be interesting to learn how the standard test number is arrived at, for it must be exceedingly difficult to get precise statistics of the kind. A fair proportion of medical men are clean shaven.

"COUNTRY SURGEON" writes about the prescribing of opium in appendicitis and other acute abdominal conditions. He rightly insists that the practice is a survival of the dark period when little was known about the maladies of the kind, and the only thing left to be done was to provide an euthanasia for the patient. Nowadays the skilled medical attendant approaches such cases, so to say, with a scalpel in his hand.

SHIP SURGEON.—Many lines make the marine insurance compulsory. We think the practice unfair in the case of a ship surgeon, who as a rule simply joins for a few voyages. It is advisable for him to see that the insurance covers *partial* as well as *total* loss. Otherwise if he escapes shipwreck with even a pocket case, he may forfeit all claim for compensation.—*Verbum Sap.*

An ordinary meeting of the Central Midwives Board, followed by a special meeting, will be held on Thursday, Feb. 9th. The Press are invited to attend at 4 p.m.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, FEBRUARY 8th.

SOUTH-WEST LONDON MEDICAL SOCIETY (Bollingbroke Hospital, Wandsworth Common). 8.45 p.m. Paper.—Mr. G. H. Makins: Some Remarks on the Indications for Gastro-jejunostomy and its Results.

DERMATOLOGICAL SOCIETY OF LONDON (11 Chandos Street, Cavendish Square, W.).—5.15 p.m.—Demonstration of Cases of Interest.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m. Mr. H. L. Barnard: Clinique. (Surgical.) 5.15 p.m. Dr. G. H. Savage: The Relationship between Suicide and Insanity.

THURSDAY, FEBRUARY 9th.

BRITISH GYNÆCOLOGICAL SOCIETY (20 Hanover Square, W.).—8 p.m. Specimens will be shown by Dr. Macnaughton-Jones. The President (Dr. W. Alexander): Inaugural Address.

HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne Street, Edgware Road, W.). 8.30 p.m. Dr. G. A. Sutherland: Clinical Observations on Lobar Pneumonia in Children.—Mr. E. L. Evans: Anterior Metatarsalgia with Notes on Seven Cases.

CHILDHOOD SOCIETY AND THE BRITISH CHILD-STUDY ASSOCIATION (Parkes Museum, Margaret Street, W.).—8 p.m. Lecture.—Dr. G. E. Shuttleworth: Some Physiological Problems in Education. (Arranged by the British Child-Study Association.)

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM (11 Chandos Street, Cavendish Square, W.).—8.30 p.m. Papers.—Mr. E. Stevenson: Notes on a Case of Large Orbital Exostosis removed by Operation (with specimen).—Mr. C. Wray: The Treatment of Tobacco Amblyopia.—Mr. E. T. Collins and Mr. R. Batten: Membranous Fibroma of the Eyeball and its Appendages.—Mr. A. Ogilvie: Exostosis of Orbit.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m. Mr. Hutchingson: Clinique. (Surgical.) 5.15 p.m. Mr. A. H. Tubby: Orthopedic Surgery.

MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (7 Fitzroy Square, W.).—5 p.m. Lecture: Mr. H. Barwell: Laryngeal Paralysis and their Value for Diagnosis. (Post Graduate Course.)

FRIDAY, FEBRUARY 10th.

CLINICAL SOCIETY OF LONDON (20 Hanover Square, W.).—8.30 p.m. Papers.—Dr. W. Ewart: A Case of "Soft Valve" Mitral Stenosis in which no murmur was heard.—Mr. E. P. Paton: A Case of Accessory Thyroid laterally placed in the Floor of the Mouth.—Mr. H. B. Robinson: Extraperitoneal Uterero-lithotomy in a Child aged three years.—Mr. D. Drew: Calculous Anuria in a Child.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m. Dr. W. J. Horne: Clinique. (Throat.)

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—4.30 p.m. Mr. R. P. Brooks: Myopia.

MONDAY, FEBRUARY 13th.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—4.30 p.m. Dr. A. G. Whiting: Electro-Diagnosis.

Vacancies.

Somerset and Bath Lunatic Asylum, Wells, Somerset.—Medical Superintendent. Salary £800 per annum, with furnished house and allowances. Applications to John Coates, Clerk to the Visiting Committee.

Craig-Leith Poorhouse and Hospital, Edinburgh.—Medical Officer. Salary £100 per annum, with board and apartments. Applications to And. Ferrier, Clerk, Parish Council Chambers, Castle Terrace, Edinburgh.

Brompton Hospital for Consumption and Diseases of the Chest.—Assistant Resident Medical Officer. Salary £100 per annum, with board and residence. Applications to the Secretary.

South Devon and East Cornwall Hospital, Plymouth.—House Surgeon. Salary £100 per annum, with board, residence, and washing. Applications to P. J. Langdon, Secretary.

Egyptian Government—Ministry of Public Instruction.—Professor of Pathology and Bacteriology at the School of Medicine, Cairo. Salary £800 per annum. Applications to the Director, Government School of Medicine, Cairo, Egypt.

Royal London Ophthalmic Hospital (Moorfields Eye Hospital), City Road, E.C.—Curator and Librarian. Salary £120 a year. Applications to the Secretary.

St. Helens.—Surgeon to the Works Sick Club. Salary £200 per annum, with furnished residence, light, heating, and attendance. Applications to P. B., Box 38, Post Office, St. Helens.

Beckett Hospital, Barnsley, Yorkshire.—Resident House Surgeon. Salary £100 per annum, with board, lodging and washing. Applications to Ralph F. Pawsey, Hon. Secretary, Barnsley.

Grove Hall Asylum, Bow, London, E.—Assistant Medical Officer (Male). Salary £150 per annum, with board, furnished apartments. Applications at the above address.

County Council of Middlesex.—Napsbury Asylum, near St. Albans, Herts.—First Assistant Medical Officer. Salary £200 per annum, with board and lodgings. Applications to Walter Geo. Austin, Clerk of the Committee, Guildhall, Westminster, S.W.

County Council of Middlesex.—Napsbury Asylum, near St. Albans, Herts.—Third Assistant Medical Officer. Salary £100 per annum, with board and lodgings. Applications to Walter Geo. Austin, Clerk of the Committee, Guildhall, Westminster, S.W.

Cancer Hospital (Free), Fulham Road, London, S.W.—Assistant House Surgeon. Salary £70 per annum, with board and residence. Applications to the Secretary. (See Advt.)

Richmond District Asylum.—Two Clinical Assistants. Salary £80 per annum, with furnished apartments, &c. Immediate Application to C. Norman, Medical Superintendent. (See Advt.)

Patrick Stead Hospital, Halesworth.—Surgeon. Salary £32 10s. per annum. Applications to Harold A. Mullens, Secretary to the Trustees, Halesworth. (See Advt.)

Appointments.

BIRMINGHAM, C. L. M.D.R.U.I., Certifying Surgeon under the Factory and Workshop Act for the Westport District of the county of Mayo.

BONNOMAN, PHILIP, M.D. Edin., a Medical Referee under the Workmen's Compensation Acts 1897 and 1900, and to act for the Central District of the Sheriffdom of Perth.

Births.

KELYNACK.—At Northwood, Middlesex, on February 1st, Violet Kelynnack (nee Violet McLaren, M.B., Ch.B. Edin.), wife of T. N. Kelynnack, M.D., M.B.C.P., of 120 Harley Street, Cavendish Square, of a daughter.

Marriages.

MAURICE—BURDETT.—On Feb. 1st, at St. Stephen's Church, Westbourne Park, Captain George Thelwall, Kinderley Maurice, R. M.C., eldest son of J. Blake Maurice, M.D., J.P., of Lyons House, Marlborough, to Olive, younger daughter of Sir Henry Burdett, K.C.B., of The Lodge, Forchester Square, W.

Original Communications.

THE TREATMENT OF POST-NASAL ADENOIDS.

By JOHN WARD COUSINS, F.R.C.S., M.D.
Lond.,

Senior Surgeon to the Royal Portsmouth Hospital and the Portsmouth and South Hants Eye and Ear Infirmary.

POST-NASAL adenoids occur very frequently in children. They are variable in size and soft, and they readily bleed on pressure. They develop on all the walls of the naso-pharynx, blocking the orifices of the Eustachian tubes and the posterior nasal apertures, causing habitual mouth-breathing, repeated attacks of chronic nasal catarrh, deafness from disturbance of the middle ear, and also mental and physical depression. The indications for operative interference can generally be recognised more by the persistency and urgency of the symptoms than by the examination of the nose and throat. The removal of these growths can be undertaken without any risk, provided there is no active disorder or any impairment of the health. After an attack of tonsillitis or catarrhal inflammation of the naso-pharynx, it is always desirable to defer the operation for a few days.

FIG. I.

Now, with reference to the mode of operating, some surgeons use curettes of many forms, while others prefer a steel finger-nail, or post-nasal forceps. In children the best instrument is the sterilised finger-nail, as it can be safely employed both to define and remove the growths in the obscure recesses of the naso-pharynx, guided by the sense of touch. I very seldom use a curette, although it is sometimes necessary in the removal of the firmer adenoids which are found in older patients.

In my operations upon children I use only the simple contrivance represented in Fig. I, and with these I have cleared the naso-pharynx in hundreds of cases, and I have had very seldom, if ever, to repeat the treatment.

The mouth-gag is a short rod of hard wood, carrying a wooden ring to regulate its insertion between the teeth, and one end of it is larger than the other, to suit the capacity of different mouths. The metal rings are simple protectors of the forefingers of the operator, and the nasal probes are made of flexible metal, and are of great utility in clearing the posterior nasal apertures.

After preparing the patient by the frequent application of some deodorising mouthwash, I always carefully examine the teeth, and remove any loose tooth before the introduction of the gag. An anæsthetic is of great assistance in clearing the naso-pharynx, but it requires very careful administration. I prefer A.C.E. or chloroform; but whatever anæsthetic is employed it must only be continued to arrest corneal sensibility, and always short of suspending the reflex actions of coughing and swallowing. As soon as the patient is ready, the head is brought well over the edge of the table, and is there supported by the hands of a nurse or the arm of a surgeon, at the same time the shoulders are raised on a pillow. The nasal probes are passed through the inferior meatuses into the pharynx; the gag is fixed in the right angle of the mouth, and the left forefinger is introduced into the

FIG. II.

pharyngeal fossa, and with it the sides and roof, the Eustachian orifice, and the posterior nasal apertures are rapidly cleared. The gag is then shifted to the left angle of the mouth, and the operation is repeated on the right side with the right forefinger (see Fig. II). The probes are now freely applied around the posterior orifices, and rubbed over the inferior nasal passages. In many cases the hæmorrhage is free, and it is necessary to have some sterilised swabs at hand to wipe the blood out of the mouth and pharynx. After clearing away the adenoids I always excise the tonsils if they are unhealthy and enlarged.

Transient shock sometimes follows the operation, and cases of troublesome hæmorrhage have been reported caused by tearing the mucous surface with forceps.

After the patient has recovered from the anæsthetic, the improvement in the hearing power and breathing is often very marked. As a general rule, I order rest and light and soft food for a few days.

THE VALUE OF BLOOD EXAMINATION IN THE DIAGNOSIS OF MANY CASES.

By WHITEHALL STEVENS, M.D.Lond.,
M.R.C.P.Lond..

Fellow of University College, London; Assistant Physician and Pathologist to the Cardiff Infirmary.

It is only in comparatively recent years that the value of a systematic blood examination in many cases which come under our notice has been sufficiently realised, but I have no hesitation in saying that before many years have passed it will be incumbent upon every scientific practitioner to be trained in so-called "hemianalysis." The technique of blood examination is comparatively simple, the apparatus necessary being a hæmacytometer, a hæmoglobinometer, and the requisites for examination of a blood-film, and in some cases it may be necessary to examine for Widal's reaction, or for the parasite of malarial fever.

In the examination of a given specimen of blood the following points may have to be observed:

- (1) *Red Corpuscles*.—(a) Number per cubic mm.; (b) sizes; (c) shapes; (d) presence of nucleated red corpuscles; (e) amount of hæmoglobin.
- (2) *Leucocytes*.—(a) Number; (b) differential count of different varieties; (c) presence of myelocytes.

(3) *Widal's Reaction.*

In connection with the subject of blood examination, there are two main practical questions to be considered:

(A) *What is the diagnostic significance of certain alterations in the blood?*

(B) *In what classes of cases met with is a blood examination indicated?*

(1).—*Alterations in Connection with Red Corpuscles.*

(a) *Number*.—The average number of red cells per cubic mm. is about 5,000,000.

A diminution in number is spoken of as oligocythæmia, and this condition is met with under many circumstances:

(i) In chlorosis an average count is about 4,000,000, but it may be much lower. In this affection the "anæmia" present depends more upon a reduction in the hæmoglobin than in the number of red cells ("chlorotic type" of anæmia).

(ii) In pernicious anæmia one finds the lowest blood counts, and an average is about 1,500,000, though it may be considerably lower. In this affection the "anæmia" present depends more upon a reduction in the number of red cells than in the amount of hæmoglobin, and indeed the so-called "colour-index" is raised.

(iii) In secondary anæmia the blood counts vary very widely. Anæmia is, of course, a feature more or less marked of most diseases, but I will content myself with mentioning a few of the more important forms of secondary anæmia:

(A) In post-hæmorrhagic anæmia an average

count is about 2,500,000, and even after exceedingly severe bleeding the count is rarely below 1,500,000.

(B) In leukæmia an average count ranges from 2,500,000 to 3,500,000, and the same may be said of Hodgkin's disease.

(C) In splenic anæmia the average is over 3,000,000, and in many cases the count is little, if at all reduced.

(D) In malignant disease the count is usually lowered, an average being about 4,000,000, but in some cases, especially in cancer of the stomach, the count is often much lower, though it rarely falls below 2,000,000.

(E) In ankylostomiasis the count may be very much lowered.

(b) *Size of red cells*.—The average diameter of the red cell is 7.5 mm. (mm. = $\frac{1}{16000}$ inch). Under normal circumstances the diameter may range from 6 to 9 mm. Smaller cells than above are called microcytes. Larger cells than above are called macrocytes.

Very large cells (12 to 16 mm.) are called megalocytes. Both macrocytes and microcytes are found in the various forms of anæmia, and the more severe the anæmia the more abundant they are. The presence of megalocytes in large numbers is suggestive of pernicious anæmia.

(c) *Shape of red cells*.—In some cases the red cells show peculiar and abnormal shapes (ovoid, rod-like, flesh-shaped, &c.). Such changes are spoken of as poikilocytosis. Poikilocytosis indicates simply a high degree of anæmia, and it may be met with in anæmia from any cause; nevertheless, it is especially pronounced in pernicious anæmia and in severe cases of chlorosis.

(d) *Nucleated red cells*.—To demonstrate the presence of these cells it is necessary to have dried and stained blood preparations. Two varieties of nucleated red cells are recognised:

(i) *Normoblasts*. These are nucleated red cells of the size of ordinary red corpuscles. Normoblasts may be found in all forms of severe anæmia.

(ii) *Megaloblasts*. These are very large nucleated red cells (11 to 20 mm.).

When these cells are found in the blood in considerable numbers they point to pernicious anæmia. In small numbers they sometimes (though rarely) are found in other forms of severe anæmia.

(e) *Hæmoglobin*.—The so-called "colour-index" of the red cell is the relation of the percentage of hæmoglobin to the percentage number of red cells. Thus, with a hæmoglobin percentage of 60 and a red cell, and a red cell percentage of 80, the colour index is $\frac{60}{80} = \frac{3}{4} = .75$.

The percentage of hæmoglobin is diminished in all cases of anæmia (primary or secondary), though the colour-index may be normal, lowered or raised:

(i) In pernicious anæmia the colour-index is always raised, an average index being about 1.5, or, in other words, the diminution in hæmoglobin is not proportionate to the decrease in the count of the red cells (each individual corpuscle is richer in hæmoglobin).

(ii) In chlorosis the colour-index is always lowered, an average being about .7, or, in other words, the diminution in hæmoglobin is out of proportion to the decrease in the count of the red cells (each individual corpuscle is poorer in hæmoglobin):

(iii) In splenic anæmia the colour-index is lowered, an average being about .6 ("chlorotic type" of anæmia).

(iv) In other forms of anæmia the colour-index is either normal or, what is more common, slightly lowered.

(2).—*Alterations in Connection with the Leucocytes.*

(a) *Number.*—The number of leucocytes in normal blood is on an average 7,000 per cubic mm., though they may vary within physiological limits from 5,000 to 10,000.

(b) *Differential count.*—The following varieties of leucocytes are distinguished:

(i) *Polymorphonuclear neutrophiles.* These constitute the bulk of the leucocytes found in normal blood (60 to 75 per cent.).

(ii) *Eosinophiles.* These number 2 to 4 per cent.

(iii) *Small lymphocytes.* These number 20 to 30 per cent.

(iv) *Large lymphocytes.* These number about 5 per cent.

(v) *Myelocytes.* These are never found in normal blood.

An increase in the number of polymorphonuclear leucocytes is termed polymorphonuclear leucocytosis; an increase in the number of lymphocytes is termed lymphocytosis; an increase in the number of eosinophiles is termed eosinophilia; the presence of myelocytes is termed myelocytosis.

In regard to leucocytosis it is necessary to remember that this condition to a certain degree may be present in health under various circumstances, and we thus have to distinguish between physiological and pathological leucocytosis.

Physiological Leucocytosis.

This affects mainly the ordinary polymorphonuclear leucocytes, and it may be found under the following circumstances: In the new-born infant, in pregnancy, after exercise, after cold baths, and after the passing of food (the count rarely rises above 16,000).

Pathological Leucocytosis.

(a) *Polymorphonuclear leucocytosis.*—This is the ordinary form of leucocytosis. Its causes are as follows:

(i) In most acute infectious diseases except measles, typhoid fever, influenza, and tuberculous disease (unless suppuration be present).

(ii) In acute inflammatory affections, such as pleurisy, peritonitis, appendicitis, &c.

(iii) In suppuration from any cause.

(iv) In some cases of malignant disease.

(v) After hæmorrhage.

(vi) In various forms of "secondary" anæmia there is often a moderate leucocytosis.

(vii) In leukaemia (*see below*).

(b) *Lymphocytosis.*—In this the lymphocytes are present in increased numbers. Lymphocytosis may be "absolute" or "relative":

Absolute lymphocytosis.—In this the total number of leucocytes is increased, and the increase is most marked in connection with the lymphocytes. This condition is characteristic of lymphatic leukaemia.

Relative lymphocytosis.—In this the total number of leucocytes is not increased, but the relative percentage of lymphocytes is raised. This condition is found normally in infants, and

is also found in many diseases (pernicious anæmia, syphilis, &c.).

(c) *Eosinophilia.*—This condition may be met with under the following circumstances: (i) In association with intestinal parasites—trichinosis, ankylostomiasis, &c. (ii) In many skin diseases, e.g., pemphigus and eczema. (iii) In spleno-medullary leukaemia. (iv) Occasionally in other affections, such as asthma and phthisis.

(d) *Myelocytosis.*—The presence of myelocytes in the blood is always pathological. Myelocytes when found in large numbers, together with a great increase in the total leucocyte count, are characteristic of spleno-medullary leukaemia. In small numbers they may be found in severe cases of anæmia (pernicious anæmia, chlorosis and secondary anæmias).

Leukopenia (a decreased leucocyte count).—The conditions under which may be found an absence of leucocytosis, or an actual diminution, are splenic anæmia, typhoid fever, measles, influenza, malaria, miliary tuberculosis, and all tuberculous affections unattended by suppuration.

(3).—*What is the Clinical Value of Widal's Reaction?*

Since an examination for the presence of Widal's reaction has become an important factor in the diagnosis of typhoid fever, the question of its real clinical value is of much importance, and in this connection the following points must be remembered:

(a) The reaction is present in about 97 per cent. of all cases of typhoid fever, and is found in over 90 per cent. of cases tested before the ninth day.

(b) The reaction is usually obtained by the seventh day, and has been noted as early as the third or fourth day.

Although in most cases the reaction appears before the fourteenth day, it may be much delayed, and only make its appearance about the twentieth day, or later still.

(c) The reaction may disappear when the temperature becomes normal, or it may persist for weeks, months, or even for many years.

(d) The reaction is sometimes "intermittent." If, therefore, a negative reaction be obtained in a supposed case of typhoid fever on the eighth or ninth day, either the diagnosis is wrong or the reaction is delayed, or, perhaps, it is intermittent, or possibly it is one of those very rare cases of typhoid fever which do not give the reaction.

If a positive result be obtained, it may be concluded that the person either has typhoid fever, or that he has previously had the disease, and this point is important, as a patient may have the disease in a mild form or he may have had typhoid fever previously, with a persisting reaction. I may say in this connection that I have known of a case of appendicitis giving a well-marked Widal's reaction, and it is only reasonable to assume in such a case that the patient has had previous typhoid fever, a history of which is sometimes difficult to obtain, as he may have suffered from the disease in a mild form.

In What Classes of Cases met with is a Blood Examination Indicated?

Having discussed the clinical significance of the various alterations found in the blood it is now necessary to examine the above question.

(i) *There are certain diseases in which a*

correct diagnosis cannot, in many cases, be made without a blood examination. These are:

(i) Some cases of typhoid fever (Widal's reaction).

(ii) Some cases of malaria (malaria parasite).

(iii) Certain peculiar diseases such as pernicious anæmia, chlorosis, splenic anæmia, spleno-medullary leukæmia, and lymphatic leukæmia.

(2) In cases presenting obvious anæmia, and in which the diagnosis is doubtful, a blood examination is of the greatest value.

In practice one commonly meets with cases in which, after inquiry into the history, after a careful consideration of the symptoms present, and after minute physical examination directed to lungs, heart, stomach, spleen, liver, urine, fæces, glands, &c., nothing distinctive can be found, and in these cases a blood examination should never be omitted, and it is especially to be remembered that a case apparently one of chlorosis may really be "secondary" to some other affection, and that one of apparently pernicious anæmia is not uncommonly really "secondary" to some other cause. In these doubtful cases a blood examination may give the following information:

(a) It may point to pernicious anæmia. In this disease the following points may be noted:

(I) Red cells:

(i) Number. This is greatly diminished. An average count is about 1,500,000, though it may be much lower.

(ii) Shapes. Marked poikilocytosis is present.

(iii) Sizes. Variations in size are very common, and megalocytes may be abundant.

(iv) Nucleated red cells are always found, and megaloblasts are present.

(v) Hæmoglobin. The index is raised.

(II) Leucocytes. These are relatively increased in number, but absolutely normal or diminished. A few myelocytes are occasionally found.

In general it may be said that a blood count of below 2,000,000, in the absence of intestinal parasites and of recent profuse hæmorrhage, is most suggestive of pernicious anæmia, and that when in addition to this one finds a raised hæmoglobin index and the presence of both megalocytes and of numerous megaloblasts, the diagnosis is amply confirmed.

(b)—It may point to chlorosis.

In this disease the red cells are diminished in number (an average count being about 4,000,000, though it may be much lower), and the hæmoglobin index is lowered. A blood examination will therefore easily distinguish between chlorosis and pernicious anæmia, and also between chlorosis and those forms of anæmia associated with leucocytosis; but it will not serve to distinguish between chlorosis and some forms of "secondary anæmia."

(c) It may point to spleno-medullary leukæmia. In this there is myelocytosis associated with the anæmia.

(d) It may point to lymphatic leukæmia. In this there is lymphocytosis associated with the anæmia.

(e) It may point to anæmia associated with eosinophilia (intestinal parasites, &c.).

(f) It may point to a "secondary" anæmia.

The red corpuscles are diminished in numbers in all cases of secondary anæmia, but the decrease is often not great (average about 4,000,000, though it may be much lower after severe hæmorrhage).

In cases of cancer of the stomach, although the blood count is often low, it is very rarely under 2,000,000. In secondary anæmias, again, the hæmoglobin index is either normal or diminished, megaloblasts are absent and leucocytosis is sometimes present.

In summing up the chief points under this heading we may mention the following facts:

(i) In pernicious anæmia a careful blood examination will usually point to the nature of the affection.

(ii) In spleno-medullary leukæmia and in lymphatic leukæmia the blood is sufficiently distinctive.

(iii) In chlorosis there may be difficulties in separating the blood condition from that due to "secondary anæmia."

(iv) If leucocytosis be present chlorosis and pernicious anæmia can be excluded.

(v) The presence of eosinophilia may be very suggestive.

(3) In cases with splenic enlargement. It is necessary to remember that splenic enlargement, associated with anæmia, may be present under many conditions, such as malaria, cirrhosis of liver (especially "hypertrophic" cirrhosis, rickets, syphilis, albuminoid disease, tuberculosis, septic conditions, infectious diseases, leukæmia, Hodgkin's disease, and splenic anæmia).

How does a Blood Examination help us in Arriving at a Differential Diagnosis?

Leucocytosis will be present in leukæmia, in septic conditions, in infectious diseases, in albuminoid disease, in tuberculosis (if attended with suppuration elsewhere), and in some cases of Hodgkin's disease.

On the other hand, leucocytosis is absent in splenic anæmia and in malaria.

The association of a large spleen with more or less well-marked anæmia is a feature of splenic anæmia, and many cases of this disease are (without a blood examination) diagnosed as leukæmia. The blood condition in splenic anæmia shows a condition like that seen in secondary anæmia—the red cells are diminished in number, but often not markedly, and the count is sometimes normal. The hæmoglobin index is lowered and sometimes a few nucleated red cells are present and also poikilocytosis. In splenic anæmia the leucocytes are either normal in number or, what is more usual, diminished, sometimes to a marked degree (leukopenia).

(4) In cases with a history of residing abroad or presenting symptoms suggesting malaria such as rigors and sweatings.

It is to be remembered that so-called "ague symptoms" may be malarial in origin, or they may be dependent upon various other affections, such as septicæmia, pyæmia, malignant endocarditis, leukæmia, Hodgkin's disease, suppuration, cholangitis, &c.

In such cases there may also be enlargement of the spleen associated with anæmia.

A blood examination in these cases is of importance, for it may show the presence of the malarial parasite, and again a condition of leucocytosis would be present in all cases not due to malaria.

(5) In cases with pyrexia of doubtful origin. In this connection it is to be remembered that pyrexia may be due to many causes which can be more or less cleared up by a blood examination, e.g.,

typhoid fever, influenza, tuberculosis, septicæmia, malignant endocarditis, pyæmia, suppuration, leukæmia (spleno-medullary and lymphatic), Hodgkin's disease, pernicious anæmia, malignant disease, malaria.

(i) The presence of leucocytosis would be against typhoid fever, influenza, malaria, tuberculosis (without suppuration), and pernicious anæmia. Leucocytosis would be met with in all the other affections, including some cases of malignant disease.

(ii) Widal's reaction would discover typhoid fever.

(iii) Splenic blood conditions would discover malaria, pernicious anæmia, and leukæmia.

(6) In cases suggestive of intestinal parasites. In trichinosis and in ankylostomiasis marked eosinophilia is present. In ankylostomiasis (except for eosinophilia) the great reduction in the red cells may simulate pernicious anæmia.

(7) In cases with glandular enlargement. A blood examination may show at once the presence of lymphatic leukæmia. In Hodgkin's disease there is a reduction in the number of red cells (average about 2,500,000), but leucocytosis is usually absent, though there may be some increase in the number of the ordinary leucocytes in advanced cases.

(8) In certain abdominal conditions. A blood examination for leucocytosis may serve to distinguish between typhoid fever and appendicitis, and between the latter disease and tuberculosis. (In tuberculosis there is no leucocytosis in the absence of suppuration.)

(9) In the diagnosis of suppuration. In acute inflammatory conditions, such as pleurisy, cholecystitis, appendicitis, &c., there is always leucocytosis, but when suppuration has occurred the leucocytosis is much increased. In severe appendicitis without suppuration the count may be up to 20,000 or even 24,000, and thus a count of above that number would point to suppuration. No absolute line can be drawn, but, nevertheless, very marked leucocytosis is very suggestive.

In this connection one point may be mentioned *en passant*; in suppuration round about the diaphragm associated with leucocytosis, it has been stated that the presence of eosinophilia suggests that the suppuration is below the diaphragm rather than above it.

CYSTIC ENDOMETRITIS. (a)

By R. D. PUREFOY, M.D., F.R.C.S.I., &c.,
Late Master of the Rotunda Hospital.

ENDOMETRITIS, either alone or as an attendant on, or complication of, some other pathological condition, claims a large share of our attention in nearly every case of uterine disease; and those who have had the widest experience will be the most ready to acknowledge how often our hopes of speedy, or even steady, improvement are disappointed. Whenever we have regard to the complex structure of the endometrium, and the periodically recurrent variations in its blood supply, on which its functional activity may be said to depend, we shall feel no surprise in observing how often these variations go wrong in excess or deficiency, and thus induce obstinate structural changes. The precise nature of these changes, the

conditions, local, constitutional, and bactericidal, which are potential in causing them, have, as is fitting, engaged the attention of many acute observers with very satisfactory results; but with regard to some forms of endometritis, for instance, that to which I wish to direct your attention to-night, we must confess their etiology is still awaiting elucidation.

I propose to bring under your notice to-night two cases illustrating the history and course of what has been termed cystic endometritis.

CASE 1.—Mrs. F., æt. 45. In fairly good health at time of marriage six years ago; in about seven months afterwards had an early abortion. Some months later, after a long journey, suffered from distressing pruritus vulvæ, which, however, yielded to treatment. In October, 1902, after missing one menstruation, distressing dorsal and abdominal pain was felt, attended with slight intermittent bleeding. Later on the bleeding became continuous, sometimes profuse, and so continued till her admission to the Rotunda in January, 1903. At this time her general condition was such as to warrant the use of medicine, at least for a time, in the hope of arresting the bleeding, and accordingly she was given that most useful uterine hæmstatic, tincture of Indian hemp in 5 minim doses twice daily, with excellent effect. This was followed by the administration of the muriate tincture of iron, and in about a fortnight the bleeding had quite ceased. Examined under chloroform, the uterus was found in normal position, the cervix healthy, and the appendages likewise. The cavity measured $3\frac{1}{2}$ inches; viscid, glairy discharge poured from it in large quantity, and the curette brought away in abundance fragments of greatly thickened endometrium. Subsequently, at intervals of three or four days, she was treated on several occasions with iodine and phenol or pyroligneous acid, and in about three weeks from the date of curetting she was allowed home apparently in a very satisfactory condition. For some months menstruation was normal, but a return of the bleeding rendered a repetition of the treatment necessary twice in 1903, and once this year, 1904, in the month of September. The tissue removed on each occasion, though much lessened in amount, presented the same microscopic characters.

CASE 2.—K. C., æt. 28, married two years; one early miscarriage. Admitted August 8th, 1903, in a very feeble condition owing to repeated bleedings; indeed, her aspect made me apprehend the presence of malignant disease.

When some improvement in her general condition had been effected by rest, feeding and tonics, she was examined, and the uterus found to be retroverted and somewhat fixed by numerous adhesions; the appendages were not reached. When dilated and curetted the amount of pulpy tissue removed was so great that I thought my apprehensions as to malignant disease were only too well founded; but examination by my much lamented friend, the late Dr. Neville, showed only the characteristic appearances of cystic endometritis. This woman was re-admitted a few months later, when it was found necessary to repeat the treatment.

The main points in these two interesting cases may be thus summarised:—

1. Both women were married, not advanced in years, and free from other disease.

(a) A Paper read before the Obstetrical Section of the Royal Academy of Medicine in Ireland, February 3rd, 1905.

2. Both had been at least once pregnant before the development of this uncommon disease.

3. Bleeding without any considerable pain was the prominent sign in both cases.

[Having regard to the marked tendency to recurrence, and the severe bleeding which attends this disease, one feels inclined to describe it as a transitional stage between benign and malignant adenoma.]

4. Recurrence took place at an early date.

5. The microscopic appearances are not like those of malignant disease, especially as regards the epithelium.

It may be urged that more vigorous use of the curette in the first treatment would have prevented recurrence, but in my opinion it is better to err in removing too little than to run the risk of rendering the endometrium permanently incapable of fulfilling its highest function, by too extensive removal of its glands.

Though the experience of only two cases is inadequate to warrant positive statements on the matter, I incline to the view that curetting, repeated if necessary, and followed by the application of the caustics commonly in use, will effect a cure.

For the safe and effective use of the latter I think we are still in want of a safe apparatus. A syringe for intra-uterine injection should be so constructed that the fluid may be measured by drops, and I have not seen one which fulfils this indication. Many years ago Dr. Barnes suggested an apparatus for carrying medicated ointments into the uterine cavity, and recently Dr. Duke has constructed an ingenious appliance by which small quantities of any caustic fluid may be safely diffused in the uterine cavity. For us in Dublin, it is, I think, of much interest to recall the fact that a Master of the Rotunda Hospital, Dr. Evory Kennedy, was the first in Europe to devise a syringe for intra-uterine use.

In cystic as in every other form of endometritis, the first and perhaps the most important indication to be fulfilled in treatment is to secure a sufficiently patulous condition of the cervical canal to admit of free escape of healthy and unhealthy discharges.

As to the choice of caustics, opinions will be found to vary widely. With regard to phenol it is well to bear in mind the narrowing of the cervical canal which is very apt to follow its repeated use, unless well diluted. I think glycerine more suitable as a diluent than spirit or water. In my own practice I have discontinued the application of caustics immediately after curetting, unless in cases of undoubted malignancy.

NOTES ON THE OCCURRENCE OF SUDDEN DEATH. (a)

By A. COCHEZ, M.D.,

Professor of Clinical Medicine at the Faculty of Medicine of Algiers.

THE occurrence of sudden death opens up many obscure problems, but is nevertheless an extremely important department of medical investigation, interesting, as it does, the physician, the physiologist, and the medico-legalist. We are far from being able to explain every case of sudden death, even after the most carefully-performed autopsy, that is to say,

hypotheses based merely on the circumstances of the death and the examination of the corpse often leave us in the dark.

As a general rule, when a medical man is asked to formulate an opinion as to the cause of death in a given case of the kind, he usually invokes aneurysm of the aorta, cerebral congestion or embolism. Now, as Brouardel remarked, aneurysm is an extremely rare cause of sudden death, since he only met with it four times in a thousand instances, while cerebral congestion (not to be confused with hæmorrhage) never once caused it. Embolism is credited with causing sudden death far too lightly, in oblivion of the fact that its existence implies a source of origin, a local lesion, capable of determining the formation of the clot (thrombosis, cardiac and arterial lesions), that pulmonary and cardiac emboli are alone capable of determining sudden arrest of life, and that in such case the symptoms preceding the fatal attack present characteristic features.

Cerebral embolism is not a cause of sudden death. It causes a local lesion, accompanied or not by an apoplectic attack; but it does not entail the functional suppression of a large cerebral area, the circle of Willis forming a vast anastomosis between the arteries of the brain, which secures a certain circulatory intercommunication between the most important encephalic segments.

For many years we were accustomed to rely on Bichat's "vital tripod" to explain death, it being always attributed to changes in one of the three essential organs of life, *viz.*, brain, heart and lungs. Brouardel referred death to the brain, heart or kidney, and the functional importance of the last-named organ has been brought into prominence during the last few years, the part played by the renal filter in physiology and pathology, and the importance of auto-intoxication in nephritis being at present universally recognised.

In short, we may affirm that sudden death is due to a cause capable of suddenly arresting the respiratory or circulatory function, acting, it may be, either directly on the heart, or indirectly through the nervous centres. This sort of inhibition may be brought about by numerous diseases, the commonest being those of the heart, the brain (or rather, the encephalon), and especially of the kidneys, the latter acting by the mechanism of intoxication. Uræmia, then, is the principal factor in the causation of sudden death, hence the importance of diagnosing and averting this intoxication, the more so seeing that it often supervenes insidiously without any outward manifestation likely to give warning.

A case in point was admitted the other day into Dr. Sabadini's service. The patient was an agricultural labourer, æt. 33, suffering from a suppurating inguinal lymphatic gland, consequent upon numerous erosions of the skin of the thigh and leg. The abscess had burst spontaneously, and there was very little discharge, the neighbouring tissues were thickened, but not very tender, and his general health appeared satisfactory. There was no cardiac murmur, and the lungs revealed no lesion of any kind, and the urine was free from albumin and sugar. Things ran their course until twelve days after admission, when he was suddenly seized with stertorous breathing, accompanied by slight, fugitive, convulsive movements of the right arm. The left pupil was dilated, the right contracted. The heart rapidly failed, and in about two minutes he was dead. At the *post-mortem* examination the brain was the seat of diffuse congestion; there was no definite lesion, but the heart was enormously hypertrophied, weighing 700 grammes. The myocardium was yellow, hard and resistant. The valves were healthy, the aorta was not thickened, and the coronary arteries were healthy. The right kidney weighed 160 grammes, and the left 162 grammes. On section it was highly congested, the cortex was obviously thinned, it was hard on section, and the glomeruli, visible to the naked eye, stood out prominently as red points, while the pyramids of Malpighi were white and dense.

These cases of fulminating uræmia, though rare, are

well known. Professor Fournier published the first indisputable case seen by him a few years previously in England. An individual was seized with malaise in the street, he entered a chemist's shop, where he was given a draught and fell dead on the threshold. The passers-by jumped to the conclusion that the chemist had poisoned his customer, and wrecked the shop. The body was removed by the police, and the coroner ordered a *post-mortem* examination, when he was found to present signs of advanced Bright's disease.

We must now ask ourselves under what circumstances uræmia causes sudden death, in other words, what are the precipitating causes of sudden death in uræmia. It must be confessed that in many instances the proximal cause escapes us, but not infrequently we are enabled to incriminate some error of diet, some intoxication of external origin, excessive fatigue—all circumstances that tend to the accumulation of toxins in the organism.

I remember the case of a journalist who, after a hearty meal, adjourned to a brothel. Already more or less under the influence of alcohol, he paid for champagne all round, and finally went upstairs with one of the inmates. Later on he passed a motion in bed, and the girl, disgusted, ran off, leaving him alone. Next morning he was found dead at the foot of the bed, the left side of the body covered with ecchymoses. Naturally the police were called in, and the body was taken to the morgue, where he was discovered to have granular kidneys. The champagne he had drunk had poisoned him, because he was unable to eliminate it, and he had succumbed to a uræmic convulsion.

Years ago, when I was house surgeon in the Children's Hospital, I remember being called to one of the porters who had been seized with a severe attack of dyspnoea. After a cursory examination I took him to be suffering from ordinary asthma, and gave him a hypodermic injection of morphia (1-10 grain). Two hours later he was cyanosed, cold, and apparently *in articulo mortis*, and careful examination showed us that he had nephritis with toxic dyspnoea. The moral to be drawn from this case is the necessity for extreme caution in the administration of drugs to the subjects of Bright's disease, especially active drugs, such as salicylic acid, salts of mercury, salts of potash, opiates and all alkaloids. Consequently, it behoves us to examine the urine of all patients very carefully before venturing to prescribe for them. I may remind you, too, that the external application of certain drugs is not free from risk. Dressings containing carbolic acid, corrosive sublimate, iodoform, &c., have often caused serious disturbances even in non-renal patients, and for this reason, surgeons, preferring asepsis to antiseptics, tend more and more to employ nothing stronger than boiled water.

In Dr. Sabadini's case, death supervened with lightning-like rapidity without any apparent cause in an individual under treatment for suppurating adenitis, who was suffering from latent Bright's disease without albuminuria. We may ask ourselves whether the iodoform dressings, renewed daily, may not have provoked acute intoxication in this patient, especially as he was already suffering from auto-intoxication consequent upon the inadequate elimination of poisons *vid* the kidneys. This case, too, reinforces the lesson that methodical, careful medical examination of the patient, completed by urinary analysis several times repeated, is indispensable if we wish to diagnose and avert the consequences of latent nephritis, failure to recognise the existence whereof exposes our patients to unexpected and fatal accidents.

Trinity College, Dublin, Hilary Term, 1905.

Final Examination, Section A.—Gustav W. Thompson, William Hutchinson, Richard A. Connell, Malcolm K. Acheson, Archibald L. Robinson and Theodore C. Somerville (equal), Charles G. Sherlock, Henry D. Woodroffe, Wilfred L. Hogan, Langford V. Hunt, Herbert J. Wright, Francis O'B. Kennedy.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON. MEETING HELD FEBRUARY 10TH, 1905.

The President, DR. FREDERICK TAYLOR, in the Chair.

DR. WILLIAM EWART described a case of
SOFT-VALVE MITRAL STENOSIS IN WHICH NO MURMUR
WAS HEARD,

in a woman, æt. 45. The existence of mitral stenosis was not suspected until it was found in the heart, which was exhibited. The clinical value of the case lay in the undoubted character of the lesion, and in the independent testimony of various observers, during a long period of hospital treatment, as to the absence of murmurs, demonstrating the fact that the characteristic bruits may sometimes be in abeyance for prolonged periods at an advanced stage, though more often in abeyance for short intervals only at an early stage. The anatomical features of the lesion, of special interest in connection with this latency, were fairly described by the term "soft-valve stenosis," which might be of use in defining a separate type of lesion in which the early fibrous changes did not, as in the "hard-valve stenosis," develop into progressive thickenings and indurations. The action of a relatively soft stenosed mitral valve must be different from that of the rigid stenosis, particularly when, as in this instance, the chordæ tendinæ and the papillary muscles were quite free from stiffness, shortening, or fibrosis. The absence of murmur where this complication was also absent might, perhaps, if observed in other cases, be an argument in support of the prevailing view as to the auriculo-systolic mode of production of the presystolic mitral murmur, and as to the share of damaged chordæ in occasioning diastolic murmurs.

DR. SEYMOUR F. TAYLOR said that mitral stenosis was the most interesting of the cardiac lesions. Its murmur was the most difficult one to time; its mode of production was not yet settled; its frequency since Gardner's paper had been well recognised. It was known that the timbre, intensity and time of the murmur depended on the strength of the heart wall. It was possible that, in Dr. Ewart's case, the murmur had been present at a time prior to observation, so that its absence was due to the mural condition. In support of this was the dilatation of the left auricle and the fatty state of the wall. He suggested that the thinness of the valve was due to an acute inflammation softening the endothelium and subjacent tissues. Had there been any pyrexia to indicate endocarditis? He thought that rheumatism causing endocarditis before puberty produced stenosis, whereas in other people it produced regurgitation; in other words, that the size of the ring was fixed by early disease, and so led to stenosis late.

DR. PARKES WEBER referred to a case of undoubted calcified stenotic valves in which the stenotic murmur had been absent for some time.

DR. PASTEUR asked whether any alteration of rhythm that is so common in stenosis cases had been observed, and also whether the first sound at the apex was suggestive of stenosis. He speculated on the relation between the clinical signs and the condition of the chordæ tendinæ.

DR. WYNTER did not think that mitral stenosis could occur in children, certainly not before the age of seven. He held that stenosis in adults was the result of a persistence of the infantile size of the ring. Nearly half of the cases of mitral stenosis that he had seen gave no history of rheumatism, which emphasised the frequency with which rheumatism was overlooked. Thickening of the valve was due to the repeated attacks of rheumatism, and perhaps the thinness of the valve in Dr. Ewart's case was due to the absence of more than one such attack.

DR. HAWKINS referred to the case of a woman who was in hospital for a month with nervous symptoms, and who died suddenly from thrombosis of the

abdominal aorta. *Post-mortem* was mitral stenosis, which had during life revealed no evidence of its existence.

Dr. FREDERICK TAYLOR showed how the murmur varied according to the two factors, the driving force and the kind of obstruction. In Dr. Ewart's case there was indisputable obstruction, so that absence of murmur could only have been due to weakness in the driving force. Temporary disappearance of the murmur was a very familiar occurrence, and he could recall numerous instances of it. In these cases he had seen *post-mortem* both soft valves and stiff valves.

Dr. EWART, in reply, said that there had been no such pyrexia in his case as would indicate endocarditis. The first sound was short and weak, but not tapping, as is usual in mitral stenosis. A cantering rhythm had been present at times. He agreed that the driving force must have been deficient, but insisted that the softness of the valve was an important factor in causing the absence of murmur. He did not know whether any murmur had been present before the case came under his observation. He did not think that adult stenosis was due to a persistent infantile ring.

Mr. E. PERCY PATON described a case of

ACCESSORY THYROID IN A GIRL, ÆT. 16.

The patient had noticed a swelling on the side of her neck in the submaxillary region for some months before coming under observation. It gave her no pain, but she was certain that it was increasing in size. It was situated in the right submaxillary triangle and could be felt from inside as well as from outside the mouth. The diagnosis before operation was uncertain, but on microscopical examination after removal it was shown to consist of thyroid tissue. A microscopical section was shown. Some points were then referred to as to the usual seats of accessory thyroids.

Mr. WALTER SPENCER referred to the researches of the late Professor His on the development of the thyroid gland. In one of the diagrams, taken from His' monograph, which he showed, an explanation of the mouth origin of that form of accessory thyroid was indicated. It was clear that it must have originated from the central part of the thyroid, *i.e.*, the thyroglossal duct, because of its position above the mylohyoid muscle. It was important to remember, when the question of operation arose, that the accessory thyroid may be the only representative of the gland, so that its removal would mean myxœdema. This had several times been caused in this way, there being no lateral lobe present.

Mr. PATON also pointed out that a lingual thyroid might be the only part of the thyroid present. Removal of part of the mass, however, usually led to a recurrence.

Mr. HENRY BETHAM ROBINSON read a paper on
EXTRA-PERITONEAL URETERO-LITHOTOMY IN A CHILD,
ÆT. 3.

The child upon whom this operation was performed was admitted to the East London Hospital for Children on June 17th, 1904, with an impacted calculus in the urethra. On examination, after this stone had been extracted, there was felt bi-manually a small hard lump on the left side of the pelvis just below its brim, which was diagnosed as an impacted calculus in the ureter. The corresponding kidney did not appear to be enlarged. After waiting a few days for the urethral wound to heal, and to see if the stone was making its way to the bladder, which it did not do, ureterolithotomy was performed and a small oval calculus removed. A fine catgut stitch was put through the outer part of the ureter and a wick drain left in the wound. There was very slight leaking for three days; after that the wound healed rapidly. There was no blood in the urine after the operation. From an experience of three cases, two in the adult and this child's, Mr. Robinson considered this to be an easier operation in the child for the following reasons: the small quantity of fat in the abdominal wall and subperitoneal connective tissue, and the shallow pelvis with the abdominal position of the bladder; the latter enabled the finger in the rectum to push the ureter with the impacted stone well up into the wound.

Mr. DOUGLAS DREW described a case of
CALCULOUS ANURIA IN A CHILD.

A male child, æt. 4, was admitted into hospital with stone in the bladder and cystitis, for which suprapubic cystostomy was performed and the bladder drained. After the operation, the child did not make good progress; the pus persisted in the urine, and there were occasional rises of temperature, and the wound did not completely heal. The child occasionally complained of pain in the abdomen, but nothing definite was found after repeated examinations except slight tenderness over the left kidney. This symptom, together with the persistence of the pyuria and irregular attacks of pyrexia, led to the diagnosis of septic trouble in the left kidney. At the end of four months, the child was seized with severe pains and a stone was found impacted in the meatus and was removed. After this, marked improvement occurred; the sinus closed, the temperature kept normal, and the condition of urine greatly improved. A month later, the child began to be sick, pain recurred in the abdomen, the urine again became alkaline, and contained pus and blood, and the wound above the pubis again began to leak; so that the quantity of urine, which had been measured daily, diminished from 25 ozs. to from 7 to 19 ozs. Two radiographs taken at intervals of a few days about this date gave negative results. A few days later, the abdominal pain became more severe, and for the first time was referred to the left inguinal region. The vomiting had increased to several times daily. Examination under chloroform: The left kidney was enlarged, the right could be felt, but not enlarged, by the rectum. Stone of triangular shape felt in the left ureter high up just below the brim of the pelvis. The left kidney was at once exposed and opened, when a calculus was found and removed. The incision was extended forwards, and the calculus in the ureter manipulated up along it and removed by incising the ureter just below the pelvis. The right ureter could be distinctly felt through the wound, and was enlarged; this was the first positive sign of trouble on the right side as the stone which *post-mortem* was found in the lower end of the right ureter had been missed on palpation *per rectum*, and there had been entire absence of symptoms on the right side. The child's condition did not permit of exploring the right kidney at the same time as the stones were removed from the left side; and although the child lived six days after the operation, the condition did not permit of any further interference. The sickness persisted, drowsiness increased, and the quantity of urine *per urethram* gradually diminished until only 2½ ozs. were passed during the last three days. The chief point of interest in the case was the difficulty in diagnosis owing to the negative results of radiography and the very slight degree of pain occasioned by the stones, although from the condition of the ureters, as shown in the specimen, the stones must have been lodged in them a long time. The case is extraordinary in that calculi were removed from the bladder, urethra, left ureter, and kidney.

Mr. PATON referred to a case of a child he had seen in Great Ormond Street Hospital, which had died with anuria a couple of days after an operation for cleft palate. *Post-mortem*, a stone blocking one ureter was found, though during life there had been no evidence of this in the urine or elsewhere.

Mr. ROBINSON said that the experience of all operators was against closing the wound after ureterotomy without drainage.

OPHTHALMOLOGICAL SOCIETY OF THE
UNITED KINGDOM.

MEETING HELD THURSDAY, FEBRUARY 9TH, 1905.

JOHN TWEEDY, P.R.C.S., President, in the Chair.

Mr. EDGAR STEVENSON read a paper on "Exostosis of the Orbit." The patient was a girl, æt. 22, first seen on November 20th, with left proptosis, well marked downwards and outwards, first noticed six months previously; increase rather rapid. She had

no pain except an occasional neuralgic twinge; the eye movements were unimpaired, the vision normal, and no diplopia. Under chloroform a small, hard mass was felt lying under the outer and upper margin of the orbit. On December 10th the tumour was cut down upon and found much larger than was expected. It was attached to the inner angle of the orbit, with its base in the frontal sinus, and it extended right across the roof of the orbit. A dense shell of bone covered cancellous tissue, so that two drills were broken in an attempt to get into it; however, a small piece was removed with a chisel and showed its structure. It was found that the attached base was not very broad, and with a pair of bone-forceps it was wrenched away without difficulty. It is an irregular pear shape, weighing 351 grains, measuring $1\frac{1}{2}$ inches by $1\frac{1}{4}$ inches, by $\frac{1}{2}$ inch. The patient made an excellent recovery, and there is no eye affection whatever.

Mr. A. OGILVY related a case of large exostosis of the orbit. The patient was a healthy man, *æt.* 24, with a good personal and family history. He was first seen in November last complaining of epiphora. A large, hard mass was felt in the orbit on the right side, evidently attached to the nasal side. The tumour was causing myopia and some choroidal changes. On January 1st, 1905, the tumour was found to have two pedicles, and proved difficult to remove. The patient made an interrupted recovery, but diplopia was present; this, however, passed off in two weeks. The questions which this case raises are these: (1) What has to be done with his disorganised lachrymal apparatus? (2) Did the tumour cause the myopia, which has now disappeared, the vision being normal? (3) Are these due to hereditary syphilis, as stated by Charles Stedman Bull? It is curious that so large a tumour could exist in such a small space as the orbit without causing more damage and discomfort than it did.

Mr. WRAY read a paper on "The Treatment of Tobacco Amblyopia." He divided the cases into three groups: (1) Those with amblyopia only; (2) those with amblyopia and tachycardia; and (3) those with tachycardia only. In view of the tendency to cardiac failure, the pulse should always be examined. He had recently seen cases where the pulse ranged from 96 to 135, and patients suffering from tobacco poisoning should be warned that tachycardia might develop. The amblyopia usually disappears if taken early, but by all the recognised treatments recovery was a slow process. As regards the tachycardia, he had seen several cases where it had persisted even after tobacco had been given up for years. He alluded to the toxic breath which was always present with amblyopia, but never when tachycardia was the sole symptom. He ascribed the amblyopia as probably due to saturation of the blood with tobacco alkaloids, and the tachycardia as due to injury or destruction of the cardio-inhibitory neurons of the trachea and bronchi. He thought that bad teeth and a catarrhal condition of the alimentary and respiratory tracts aided the absorption of the poisons. Being much dissatisfied with the orthodox treatment with potassium iodide and strychnine, and considering that nicotine was freely soluble in water, he had seen great and rapid improvement follow from the following treatment:—The patients were directed to dress warmly and drink a pint of water at 7 a.m., and walk briskly for thirty minutes in the open air. Then to drink a second pint and go for a similar walk. Then rest for a few minutes and take breakfast. A third pint is to be taken in the middle of the morning, and a fourth in the middle of the afternoon. Some have even continued to smoke as much as a quarter of an ounce a day, and in three cases practically normal vision was restored in fourteen days. As regards the effect of the water treatment on the heart, the author had not had the opportunity of trying it on the new cases he had lately seen, for this had not been a marked symptom in them, but unquestionably the accelerated beat he had noticed had not disappeared in the same way as the amblyopia. There was considerable doubt as to the method in which nicotine was eliminated, but he thought that it

was mostly by the kidneys, though the lungs and skin probably bear a share. The water treatment had the advantage of utilising all three ways.

Messrs. E. TREACHER COLLINS and RAYNER D. BATTEN read a paper on

NEURO-FIBROMA OF THE EYEBALL AND ITS APPENDAGES.

The case which formed the basis of this case was a girl, *æt.* 14, who had been under Mr. Batten's observation for three years. The right eye was buphthalmic with vision of 1-60. There was also much hypertrophy of the upper lid. There was a doughy swelling over the right temporal fossa. The condition dated from birth. This unsightly eye was excised, together with a wedge-shaped piece of the upper lid. The microscopical condition of the lid showed it to be a case of congenital elephantiasis associated with plexiform neuroma. The chief interest centres in the eye, for it is the fourth case recorded in which neuro-fibroma of the eyelid has been associated with a buphthalmic eyeball. This condition, however, does not seem to be due to fibromatosis of the ciliary nerves, but to increase of tension due—as in another case recorded by Mr. Collins—to congenital adhesion of the root of the iris to the back of the cornea. The terminal nerves in the cornea were, however, thickened. The condition seen in the choroid has not before been noted. Throughout its structure was denser than normal, and in parts it was considerably thickened. It was chiefly composed of fibrous tissue, highly nucleated, with pigment cells present, and very few blood-vessels. Numerous small oval bodies presented the appearance of enlarged nerve endings. By comparison with the other cases recorded it was shown that all portions of the ciliary nerves supplying the eye may be affected with congenital fibromatosis; and that the uveal tract, like the skin, may be affected with a general hyperplasia of the fibrous tissue, though the extent of the affection varies. In some only the terminal filaments and end organs are involved, and in others the larger trunks are also affected.

HARVEIAN SOCIETY OF LONDON.

CLINICAL MEETING HELD AT THE STAFFORD ROOMS, JANUARY 26TH, 1905.

MR. JAFFREY in the Chair.

Dr. J. J. PERKINS showed a man suffering with Addison's Disease. There were pigmented spots on the skin and in the mouth. There had been faintness on micturition; no vomiting.

Dr. WINSLOW HALL remarked on the asymmetry of the thorax which he had observed in another case. This was thought to be only a coincidence.

Dr. J. J. PERKINS also showed a young man suffering from Bronchiectasis, who had been much improved by tracheal injection of creosote in oil. He had gained in weight. Dulness was extensive at the left base; the heart was displaced. Only a few *râles* were now heard. Clubbing of fingers.

Mr. JAFFREY remarked upon drainage in these cases.

Dr. PERKINS thought it was only of use where there existed a large basal cavity, and not in presence of several small cavities.

Dr. BATTY SHAW showed a patient with Recklinghausen's Disease associated with Dilated and Dropped Stomach. W. G., *æt.* 27, a French polisher, for the last three or four years has been troubled with some attacks of pain in the right loin, radiating round the back and down to the right testicle. In twelve months he had lost a stone in weight. When first seen at University College Hospital in February, 1904, he had bad appetite, pain, and vomiting; a slight increase of the stomach noted in the left axilla and a slight splash in the left hypochondrium; the skin was somewhat pigmented and some small flat moles were noticed on the abdomen and near the axilla. The patient was admitted under the care of Dr. Sidney Martin. The pains continued, requiring morphia; the radiographic examination for renal calculus was negative; the urine

was quite normal; examination under an anæsthetic revealed nothing. Mr. Godlee then saw the patient and discovered on the body and head twenty to thirty small subcutaneous masses which caused pain on pressure; two were excised and found to be fibromata lying in close relation to nerves. A few days ago the patient was again examined. The pigmentation and flat warts had increased. In addition the stomach was found to be lying in the suprapubic region; it was greatly distended and when in peristalsis caused severe colicky pain. No tumour could be felt.

Case was discussed by Mr. JAFFREY, and Dr. SUTHERLAND inquired as regards treatment of the condition. It was proposed to hand the case over to the surgeon.

Mr. LAMING EVANS showed a case of severe multiple deformity in a girl, æt. 14, following infantile paralysis at fourteen months, which had received no treatment. Besides a severe lateral deviation with rotation of the spine, a bulging of the anterior abdominal muscles, and a double calcaneo-cavus, all of paralytic origin, there was a contracture at the hip-joints of 135°. As a compensatory curve, the degree of lordosis was extreme. As the ileo-psoas on the right side was active, it was hoped that the child would be able to walk after the deformities had been corrected, and a suitable appliance fitted.

Dr. GUTHRIE thought this was the most severe case he had seen after infantile paralysis. He was not sanguine that any beneficial results would follow from the use of electricity.

Mr. LAMING EVANS showed a case of a man, æt. 60, with a rupture between the long head of the biceps cubiti and its tendon. The long tendon could not be felt, but that of the short was well defined, and by means of this tendon all the functions of the whole muscle were well carried on, but with somewhat diminished vigour. There was no displacement of the head of the humerus.

Mr. JAFFREY thought the short head was torn.

Mr. E. PERCY PATON related the case of an acrobat who had ruptured several muscles in succession through attempting various feats. In some cases of rupture of the short head of the biceps the patient was hardly conscious of the occurrence.

Dr. MAURICE SQUIRE showed a man, æt. 31, a dust-man. *History*: Right otorrhœa all his life; gonorrhœa and sores, but no secondary symptoms. Two weeks before Christmas, 1904, he commenced vomiting, which has continued intermittently ever since, with headache. He complains of frontal headache of variable intensity. Vomiting is occasional, and with a little preceding nausea. Mentally rather dull. No alteration of sensation or movement. No inco-ordination. No localised tenderness. Doubtful flattening of left face. Eyes—normal movements, but marked right optic neuritis. Ears—an old dry perforation in left ear and a large polypus removed from right ear, where there is a slight discharge. A few days ago he had some retraction of the head. The case has rather improved since the removal of the polypus, but the symptoms and physical signs suggest the question of cerebral or cerebellar abscess. As there was no localising symptom he proposed to wait and watch events.

Mr. JAFFREY had found a cerebral abscess on the opposite side to that on which he trephined in two cases, also in a case of cerebral tumour the same thing happened.

Dr. SCOTT thought the headache was not typical in this case. Optic neuritis was certain. There was a possibility of antral mischief being the cause of trouble, and he advised its exploration.

Mr. PERCY PATON showed a man, æt. 55, who noticed a swelling on the right side of his neck nine months ago. This steadily increased in size. The main mass lies under the sterno-mastoid muscle to which it is fixed, and it also has firm deep connections. Its outline is irregularly rounded, its consistency firm. There are several outlying masses similar in nature. One or two can be felt in front of the left sterno-mastoid. The man has lost some flesh and has a good deal of pain. There is no growth to be found in the pharynx,

larynx, or mouth, nor is there any other abnormality. There is no history, nor is there any evidence of syphilis, and the man has had a good deal of potassium iodide without any improvement. He thought there could be no doubt that the masses are malignant and inoperable, and also that the growth is primary in the neck, either being sarcomatous and commencing in the glands or carotid body, or possibly epitheliomatous in connection with the remains of one of the branchial clefts. His impression was that it is an endothelioma beginning in the lymphatic glands or the carotid body.

Mr. LOCKHART MUMMERY remarked on the possibility of the tumour being in connection with the branchial cleft.

Mr. E. PERCY PATON showed the case of a boy, æt. 16, who first came under his care in August, 1903, with the history that for several years he had been troubled with some increased frequency of micturition and pain, which had recently given him greater trouble. On examination he was found to have a large quantity of urine in his bladder which, through a full-sized catheter, he was unable voluntarily to pass, the amount just being under four pints. The bladder wall had practically no contractile power, but no other defect could be found. His urine was a little low in specific gravity, but otherwise normal. He was put under an anæsthetic, but careful examination of the rectum and abdomen revealed nothing, and sounding gave a negative result. He was then treated by tying in a catheter for some weeks, but without doing him any good. It was then thought that possibly the more thorough drainage which could be got by a suprapubic opening might allow the bladder to return to its normal size, and a suprapubic opening was therefore made, and the interior of the bladder as far as it could be reached examined. It seemed in every way normal, except for its great size. A tube was then tied in and the cavity drained for from three to four weeks. The tube was then removed and the opening allowed to heal, which it did very slowly. It remained closed for five months, but has since reopened and leaks a certain amount; the dilatation of the bladder, however, has not been at all relieved, but he is kept very fairly comfortable by the passage of a soft catheter, which he uses twice a day. A careful investigation of his history throws no light on the cause of his trouble. He has had no injury to his back of which he has any knowledge, nor has he at any time so far as he knows ever distended the bladder. His reflexes are normal and no evidence can be obtained of past diphtheria or other disease likely to interfere with the nervous mechanism of the bladder.

Mr. JAFFREY mentioned the case of a boy pushed into a bath; admitted with a large bladder. The urine had to be drained off. It recovered its tone in time.

Mr. PARDOE mentioned three cases bearing somewhat on this. All had inability to empty the bladder. There was a variable flow according to pressure. In the first case a pouch with stones in it was discovered after suprapubic operation. In the second case, a man, æt. about 40, had dilated bladder and a pouch also was found. He advocated in Mr. Paton's case tying in a catheter and allowing to heal. If not, to remove the scar of the wall of the abdomen and of the bladder.

Dr. LEONARD GUTHRIE showed a man, æt. 52, who had for seven or eight years complained of increasing difficulty in walking. The pupils were equal and the reaction normal. There were defective upward movements of both eyes, imperfect convergence and nystagmus on all ocular excursions. The optic discs were excavated, the cribriform plates exposed. Vision was only slightly impaired. His gait was typically cerebellar with a strong tendency to swerve or fall to the left. The knee-jerks were exaggerated. Ankle-clonus absent. Sensation was normal and there were no lightning pains. He had never suffered from headache or vomiting. Speech and hearing were normal, also heart, vessels, and urine. There was no history of syphilis. The condition was probably one of steady progressive degeneration in the neighbourhood of the

Corpora quadrigemina and perhaps of the left cerebellum or its peduncles. It would probably result in paralytic dementia or tabetic general paralysis.

Dr. ALEXANDER MORISON showed a case of *Bilharzia hæmatobia* in a man, æt. about 30, who had been a cavalry soldier in the South African war. Hæmaturia was first noticed after bathing in the Blood River in the Transvaal. The act of urination began by the evacuation of a comparatively clear urine and terminated with the escape of deeply blood-stained urine. The final phase of micturition was painful. Some bleeding in defæcation. From the duration of his symptoms the patient was anæmic and the microscope revealed blood-cells and the ova of *bilharzia hæmatobia*. Treatment was of little avail.

Mr. JAFFREY remarked on the duration of these cases, and Mr. PATON had seen the ova in a tumour of the skin—a rare occurrence.

Mr. PARDOE remarked on the unusual occurrence of complications of this disease in England as compared with Egypt. The cystoscopic appearance of the bladder was interesting in this disease. He made no suggestions as to treatment.

Dr. ALEXANDER MORISON showed a case of Regurgitation through the Aortic Valves, in a man, æt. 49, associated with cardiac pains commencing in the præcordium and radiating into the left arm. The patient had suffered from rheumatic fever when a child, æt. 9, had had small-pox when æt. 22, and had worked hard as a builder's labourer. He was not aware that he had disease of the heart until two years ago, when he began to suffer from cardiac pains. Dr. Morison ascribed the aortic lesion to the early rheumatism, and considered the case of some interest from a prognostic point of view.

Dr. SUTHERLAND doubted whether the aortic lesion dated from childhood. He thought it more probably was to be attributed to atheroma.

Mr. LOCKHART MUMMERY showed a Sigmoidoscope—a modification of Strauss'; it was to be passed in the genupectoral or in the Sims' position. The instrument was 30 c.m. long. The instrument need not touch the bowel-wall on introduction, but should be guided by sight. It could reach to the middle of the sigmoid flexure. It was a useful substitute to exploratory laparotomy where the finger could not reach the site of the disease. [Drawings to illustrate cases diagnosed by its means (papilloma, &c.) were shown.]

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD FEBRUARY 1ST, 1905.

PROFESSOR CHIENE, President, in the Chair.

MR. J. W. DOWDEN read a paper on

RECURRENT TORSION OF THE SPERMATIC CORD.

Torsion of the cord occurred with greater frequency than was generally supposed, but the condition was apt to be overlooked, as it was but scantily referred to in most text-books. Two varieties occurred—(1) A sudden and acute degree of torsion, leading to atrophy of the testicle; (2) more or less frequent recurrence, with or without the eventual onset of an acute degree of twisting. A good deal had been written about the first of these, but not on the second, and this paper, based as it was on five cases of recurrent torsion personally observed, was devoted chiefly to the latter. *Predisposing causes*: The main cause seemed to be a "floating" condition of the testicle (present in all five cases), the testicle, epididymis, and cord being completely surrounded by the visceral tunica vaginalis and hanging free like a fruit on its stalk. Another cause, also found in all the writer's cases, was a broad, flattened arrangement of the cord with separation of its constituents, so that while the vas went to the globus minor the vessels entered the globus major—so-called inter-mesorchial separation of the cord. Either

testicle seems equally liable, and torsion may occur in undescended or descended testicles. Most cases occur at or after puberty, but torsion may take place in infancy, and if so it is almost always incorrectly diagnosed as acute orchitis. Acute torsion often occurs in an undescended testicle. The *exciting causes* of torsion are uncertain. It may come on at night, after strains, coughing, &c., or after crossing one leg over the other. Sudden action of the cremaster muscle has been supposed to produce it. Patients usually came under observation either on account of a more severe attack than usual, or after such an attack had just been passed through, or to avoid the annoyance of repeated recurrence. In these there was a history of sudden sickening, pain in the testicle, a variable amount of collapse, tenderness of the testicle and epididymis, involuntary flexion of the thigh, scrotal swelling developing in a few hours from the onset, and great prostration until relief was obtained. This took place suddenly, the scrotal swelling subsiding twenty-four hours later. These attacks occurred at intervals of weeks or months, sometimes for many years together. On examination during an attack the above points could be made out. Fluid collected in the tunica vaginalis in an hour or two, a tender knot could be felt in the cord, the epididymis might be found to be placed anteriorly, and there was a little rise of temperature. On examination during the intervals the testicle was raised and somewhat horizontal. Rotation round a vertical axis was painful, and the organ was smaller than normal. The *diagnosis* had chiefly to be made from orchitis and hernia. In the former the sudden onset with collapse, the early and intense local symptoms, the knot in the cord, and the altered position of the organ, as well as the absence of urethritis or mumps, were the chief guides. Strangulated hernia was sometimes simulated either by a descended or an undescended testicle in which torsion had occurred. In the former case the pain was followed by swelling (not *vice versa*, as in hernia), the inguinal canal was free. If the testicle were undescended, its absence from the scrotum, along with the presence of a lump in the inguinal canal, preceded by pain, was suggestive. In cases of doubt it was best to operate. In all probability the alleged frequency with which undescended testes became inflamed was really explicable by their liability to torsion. Twisting usually took place from without upwards, and might be through an arc of from 180° to two complete turns. In an acute case venous obstruction resulted; the cord and epididymis became engorged, the testicle doubled its size, and the hernia contained blood-stained fluid. The veins of the cord were flattened, but the artery was pervious. The testicle was completely destroyed by a hæmorrhagic infarct; there was no necrosis, only atrophy. In recurrent cases the repeated attacks of congestion resulted in fibrosis and atrophy. *Prognosis*: The condition is never fatal; attacks will continue to take place and probably there will ultimately be one so severe as to lead to atrophy. *Treatment*: During an attack detorsion should be attempted, the testicle being twisted from within outwards, so as to undo the most common variety of twist; if this caused pain or if there was resistance the reverse direction should be tried. If detorsion failed, operation should be had recourse to at once. In the intervals the treatment consisted in operative fixation of the testicle. The steps were to open the tunica vaginalis, clip away part of the visceral layer, and scrape the testicle, and then suture it below to the dependent part of the scrotum, taking care that there was no twisting of the cord. This operation Mr. Dowden had performed on several occasions, with good results. His first case had been so treated three years ago, and there had been no recurrence.

Mr. DAVID WALLACE congratulated Mr. Dowden on having had so many instances of a comparatively rare malady. He had only seen one case of torsion of the cord in many years.

Mr. MILES described a case of atrophy of the testicle

which followed torsion of the cord caused by falling from a branch of a tree. He thought that the action of the cremaster might readily bring about twisting.

Dr. FLEMING read a paper on

MASSAGE, PASSIVE MOVEMENTS, AND MODIFIED RESISTED EXERCISES IN THE TREATMENT OF ADVANCED CARDIAC DILATATION.

After mentioning the comparatively disappointing results of the Nauheim treatment, the speaker said that during the past few years he had tried the plan of treating cardiac dilatation, with and without valvular defect, by successive periods of massage, followed by passive movement, and then by resisted exercises, with astonishing benefit in cases in which rest and cardiac tonics had failed. Among the various theories promulgated to explain the benefits of such modes of treatment, he mentioned Schott's view that by periodical stimulation the nutrition of the heart muscle is improved, that its contraction becomes more complete, and exercise first raises, then lowers, the blood pressure. Sir Douglas Powell believed that in addition to the general action of massage the heart was stimulated to fuller systole, while Broadbent ascribed the good effects of massage to dilatation of the peripheral vessels and consequent relief to the left ventricle. Lauder Brunton thought that exercises might dilate the splanchnic vessels and thus relieve the right heart. Dr. Fleming believed that massage and exercises braced up the muscle of both sides of the heart; the method was of value as an adjunct to other lines of treatment in many cases of cardiac dilatation, particularly in extreme degrees of that condition. Notwithstanding all that had been said as to the impossibility of accurately gauging the size of the heart by percussion, he also thought that careful observations, taken along with the position of the apex-beat, gave sufficiently definite data, if records were taken from time to time. The method he employed was quite simple. The entire series of exercises prescribed by Schott was not carried out, but they were limited to such movements of the arms and legs as the patient could easily make in bed, and no particular movements were ordered. The duration of the exercises was based on these effects, fatigue never being allowed. When the period of resisted exercise was over, the patient was allowed up, and a few minutes' slow walking was enjoined. Among the cases quoted were the following:—*Case I.*: Female, æt. 47, great dilatation of the heart as compared with previous measurements, the apex-beat being under the seventh rib on the anterior axillary line, and the right border $2\frac{1}{2}$ ins. outside the lateral sternal line. There were systolic, mitral, and tricuspid murmurs, venous engorgement, and irregular pulse. The patient had been confined to bed for six months, and notwithstanding cardiac tonics, she was constantly on the verge of total failure of compensation. After ten days' massage, and a similar period of passive and then resisted exercises, the patient so far improved as to be able to rise on the twenty-first day, and take walking exercise, at first for five minutes, then increasing. The pulse-rate fell to normal, and the irregularity diminished; the apex crept into its old place in the mid-clavicular line under the sixth rib, and the right border contracted to $\frac{1}{2}$ in. to the right of the sternum; in fact, compensation was sufficiently established to allow the patient to take moderate exercise and undertake light work. *Case II.*: Female, æt. 73, with dilatation of the heart and mitral disease. Apex-beat in the seventh space, 8 ins. from midsternum. Dyspnoea, epigastric pulsation, irregular pulse; right border 3 ins. to right of sternum, œdema of lungs, and diminished urine. Very little improvement after seven months' treatment in bed with cardiac tonics. Massage was begun on August 2nd, passive movements on the 9th, and resisted exercises on the 16th. A week later the patient was allowed up for two hours and the exercises were replaced by a short walk. At the same time the size of the heart diminished, and the pulse slowed. Of other eight cases, three were men and five women. Two had aortic and mitral incompetence, and in them the treatment failed; six had mitral and

tricuspid incompetence, and in them it succeeded. Even eight successes out of ten cases seemed to warrant further trial; aortic cases, apparently, were not suitable. As to the permanence of the results: In four cases considerable periods (two years to six months) have elapsed without any failure of compensation; only one case is known to have relapsed.

Dr. G. A. Gelson and Dr. W. Russel discussed the paper.

Dr. GIBSON read a paper on

BRADYCARDIA,

with a lantern demonstration. He considered only true bradycardia, and not that false form in which the slowing of the pulse was due to beats not reaching the periphery. After a brief historical introduction, the nature of the symptom-complex was referred to—slowness of pulse, paroxysmal or permanent, and accompanied in some cases with apoplectiform or epileptiform seizures. The etiology of bradycardia was next considered. Causes were either *exoteric* or *esoteric*, and among the former he named idiosyncrasy (as in cases in which bradycardia was a family affection), nervous factors, toxic agencies, and structural changes in the heart and vessels. Of nervous factors we had such causes as intra-cerebral pressure, cerebral syphilis, meningitis, and tumour of the base of the brain; and, again, reflex causes, such as hepatic or renal lesions, causing paroxysmal bradycardia. Examples of bradycardia from functional nervous causes were to be found in the cases of Colonel Townsend, who had the power of slowing his heart at will, and of fakirs, who are credibly reported to maintain a very infrequent cardiac beat for long periods through vagus inhibition. Among toxic agencies producing bradycardia he enumerated lead poisoning, digitalis, tobacco, and the poisons of diphtheria and typhoid, as well as uræmia and the puerperal state. Most important of all the exoteric causes were structural changes—arterial and cardiac degenerative lesions, and the condition described as hypertonus. The esoteric, or intrinsic, influences producing bradycardia act by interfering with the auricular and ventricular rhythm. In some cases it seems as though the whole heart is slowed; sometimes there seems to be a very feeble ventricular beat which does not reach the periphery, and sometimes the ventricle does not beat at all, though the auricles do. There was no doubt whatever that the auricles gave both audible and tangible evidence of their activity; tracings were shown in which three or four auricular pulsations took place for every one beat of the ventricles. Probably in many cases the conductivity of the auricular impulse was interfered with, and the ventricles did not respond to the stimulus conveyed to them by that band of muscular fibres reaching from the right auricle to the left ventricle, known as Gaskell's bridge. The alterations in cases of bradycardia due to esoteric causes could be analysed under four heads: (1) Modifications of stimulus to the ventricles; (2) modification of productivity of impulse; (3) modifications of excitability; and (4) modifications of conductivity. A number of cardiograms were shown illustrating various alterations in the cardiac rhythm, and the way in which they ought to be interpreted was pointed out. In some cases, where the heart was acting slowly, one or more sounds could be detected between the first and second sound; these were regarded as auricular in origin. They were especially present in cases of senile bradycardia with systolic murmurs. The chief types of the condition were: (1) Permanent bradycardia; (2) permanent bradycardia with syncope or other seizures; and (3) paroxysmal bradycardia with similar attacks. There was often also glycosuria or albuminuria. In his view the Stokes-Adams syndrome was of the nature of an intermittent claudication of the arteries of the base of the brain. The cardiac slowing depended on inhibition; the inhibition was brought about by the apoplectic or epileptic explosion, and this in its turn was due to some change in the vascular current in the brain.

Dr. Mackenzie and Dr. Russell discussed the paper.

LIVERPOOL MEDICAL INSTITUTION.
MEETING HELD FEBRUARY 2ND.

DR. JAMES BARR, the President, in the Chair.

MR. F. T. PAUL exhibited a patient suffering from Popliteal Aneurysmal Varix, which had resulted from a bullet wound.

DR. M. LOEWENTHAL demonstrated a specimen of *Bothriocephalus Latus* and mentioned the treatment he had adopted in the case from which it was obtained.

MR. F. T. PAUL read a note on Enterectomy for Cancer of the Colon. Three recent cases were mentioned, and the portions of the bowel removed were exhibited. Especial attention was directed to the importance and difficulty of making an early diagnosis, many cases of cancer of the cæcum being confounded with appendicitis. As regarding malignancy, these cases gave the best permanent results in the surgical treatment of cancer, and as regarding the dangers of the operation he had not lost a single case, except when intestinal obstruction was present, since he had brought the ends of the bowel outside at the time of the operation. He would very much like to know what the real mortality was after primary end-to-end anastomosis of the large bowel. As a palliative operation he advised short-circuiting whenever it was possible, rather than performing colotomy.

MR. THELWALL THOMAS had taken advantage of the method of operating described by Mr. Paul, in several cases of colectomy, and considered it a valuable advance. Cases being so often seen when marked obstruction had supervened, he had found it impossible to unite the dilated proximal end of the divided gut to the atrophied and collapsed peripheral portion.

DR. E. M. STOCKDALE, MR. P. P. NEWBOLT, DR. J. HILL ABRAHAM, DR. G. C. WALKER, DR. W. BLAIR BELL, DR. W. CARTER, DR. R. HUMPHREYS and the President also took part in the discussion.

MR. T. C. LITLER JONES related a case of Acute Hæmorrhagic Pancreatitis. The patient was a healthy woman, æt. 26, subject to constipation. She was suddenly seized with severe abdominal pain and vomiting forty-six hours before admission to hospital. Laparotomy was performed and there was found to be fat necrosis and about three pints of blood and serum in the peritoneal cavity. This fluid was removed and the pancreas incised in its long axis, with a view to prevent further tissue necrosis due to the action of the ferment. The incision in the pancreas was packed with gauze, which was removed thirty-six hours later. Except for some trouble with the abdominal incision owing to the digestive action of the pancreatic discharge, the patient made an uninterrupted recovery.

DR. W. B. WARRINGTON read a paper on Compression Paraplegia with especial reference to Tumour of the Spinal Cord, and an account of a case of endothelioma removed from the cauda equina. He pointed out that in any case of paraplegia the possibility of compression of the cord was to be considered. Tumours of the spinal cord were about ten times less frequent than cerebral tumours, but about half could be successfully removed, as against 4 per cent. of cases of cerebral tumour. The symptoms were progressive pain, motor paralysis and sensory paralysis. The clinical picture of total block of conduction between the cord and the brain was described, and reference was made to the splanchnic and somatic symptoms in these cases. Cases were then quoted to show that this "block" might be physiological and remediable, calling in selected cases for operative interference. In the case of the patient with a tumour of the cauda equina, there were symptoms of symmetrical affection of the sacral roots—pain, paralysis of the muscles moving the feet, loss of sensation in all the sacral and last lumbar area, disturbance of bladder and rectum and loss of the bulbocavernosus reflex. The tumour which was removed by Mr. R. W. Murray proved to be a malignant endothelioma, and though marked relief occurred for some months, the symptoms then reappeared and the case could only end fatally. The importance of differ-

ential diagnosis between lesions of the last part of the cord (conus medullaris) and the cauda equina was emphasised, as in the latter case the surgeon could often satisfactorily operate. A brief account of the diagnostic features of the different lesions, and their distinction from each other, was given. In many cases of nervous disease the co-operation of physician and surgeon was most desirable.

The President, Professor Sherrington, Mr. Damer Harrison, Dr. Nathan Raw, Mr. R. W. Murray, and Dr. Hill Abram took part in the discussion.

PARIS, February 12th, 1905.

EARLY TREATMENT OF CONSUMPTION.

Is it possible to cure consumption? asks Professor Renon. It is possible, and even very probable in the majority of cases, as it has been said that tuberculosis of the lung was the most curable of chronic diseases. This malady can be almost always cured in the incipient stage. Yet there are some, by reason of hereditary taint or some other unfavourable condition, who are not amenable to any treatment, however active.

The therapeutic arsenal for the treatment of pulmonary tuberculosis is well stocked, and even overstocked, remarks Prof. Renon. If we possessed the specific remedy for tuberculosis as we do that of diphtheria, the question would be very simple. Unfortunately, such is not the case. Neither the tuberculin of Koch nor the new tuberculin T.R. have given decisive results. The same may be said of the series of serums recommended by men of good faith and of undeniable scientific standing.

One of the best remedies to be utilised in phthisis is arsenic. It may be given in very small doses:

Arseniate of soda, 1 gr.;
Water, 10 oz.

A tablespoonful twice a day at meals, and continued twenty days a month for three or four months. There are other preparations of arsenic, such as cacodylate of soda and arrhenal. The former is employed by the mouth, the rectum, or subcutaneously. M. Renon prefers the latter mode. He injects one grain dissolved in twenty drops of sterilised water every two days, or eight injections in sixteen days. He then suspends them for eight days and recommences the series. Arrhenal may be employed in the place of cacodylate of soda, but M. Renon thinks it inferior. The *raison d'être* of the arsenical treatment is to keep the patient in good condition and increase his weight if possible, but it should be used with prudence.

Creosote was considered a kind of specific for phthisis for many years, but it frequently aggravates the condition of the patient by fatiguing the stomach, and, on the other hand, it has frequently provoked hæmoptysis. In certain torpid forms of phthisis, however, creosote might be given by the rectum in twenty to thirty drop doses. Synthetic preparations, such as guaiaicol or thiocol, may replace creosote. Thiocol given in 10-grain wafers three times a day has much benefited some patients.

Besides creosote, and acting in a different manner, is urea, utilised first by Harper in England, which has a favourable action in all forms of tuberculosis. It can be employed in subcutaneous injections and by the mouth. Prof. Renon gives it in wafers containing 12 grains each, two to four daily. Tannin is also an excellent preparation, but, unfortunately, this is ill tolerated by the stomach. It has been given in wafers:

Tannin, 5 grs.;
Phosphate of lime, 10 grs.

For one wafer; five daily.

Tannigen is a good substitute in the dose of 4 grains three times a day. The glycerophosphates have a good action on the general nutrition. Two or three 5-grain doses daily before meals. Lately M. Renon has been employing with much benefit a new phosphated

substance called phyline, described by Posternak, which is a phospho-organic principle of vegetal grains. It is well tolerated, improves the appetite, and favours sleep. He gives 10 grains of it before the two principal repasts.

One of the complications of pulmonary consumption is fever. For this rest in bed will frequently be sufficient. Otherwise antithermics must be given. Of these there are a host, but those which have given the best results are aspirin and cryogenin, discovered by Lumière, of Lyons. Either of these agents may be given in four grain doses twice a day, at three o'clock in the afternoon and at six o'clock.

Two other symptoms frequently require attention—hæmoptysis and diarrhoea. The former will be treated by the classical remedies, needless to mention. The diarrhoea is best treated with:

Cotoin, 2 grs.;

For one wafer; two daily. Or—
Methylene blue, 2 grs.;

Lactose, 4 grs.

For one wafer; two daily.

For the cough M. Renon recommends a half-grain of opium two or three times a day.

Germany.

BERLIN, February 12th, 1905.

At the Medical Society the discussion on Lesser's paper on the

FINSEN LIGHT TREATMENT OF LUPUS was continued.

Hr. Levy-Dorn said that the violet and ultra-violet rays did not work sufficiently on the deeper structures; they were aided by the heat-rays. Even if the cooling apparatus prevented the warmth being felt, the heat rays still passed through. It could not be doubted that cures actually took place under the treatment. If the treatment did not answer in all cases, it was still very unirritating. Photocautic, which was perhaps too little employed, was an active supporting agent. It was to be wished that the apparatus should be made more perfect and simplified. It appeared as if that introduced from Paris by Marie might be considered an improvement.

Hr. Holländer complained of a something wanting, in that the treatment was not suitable for lupus of the mucous membranes. On the other hand, any particular spot could be reached with hot air. The speaker had obtained the best results when he had thoroughly cauterised first with hot air, and had continued the treatment with the Finsen light, or by placing over the parts a radio-active substance. An advantage of the newer methods over the old was that they acted without actual contact. As regarded cosmetic effect alone, where the lupus was not too extensive the Finsen treatment was most advantageous. The treatment, however, must follow the nature of the case. In any case it was desirable that lupus patients should be treated at special establishments, where all means of treatment were at hand.

Hr. Blaschko observed that chemical agents also acted electively—caustic potash, hydrochloric acid and also the slower acting pyrogallic acid. If any individual lupus nodules remained behind they might heal up as foreign bodies without reaction; in any case extension was slower. In order to destroy such individual nodules the Finsen light treatment was suitable, or perhaps the application of a radio-active substance. Sufficient value had not been placed on tuberculin in the treatment of lupus; he had often employed it with good results.

Hr. Kromeyer disputed the statement that the action of the light was a caustic one. Rather, a serous saturation of the nodules took place after illumination, new connective tissue developed, and the tubercle died. The value of the light treatment and its excellent cosmetic results depended on the fact that the treatment initiated this physiological process.

Hr. Senator mentioned a very extensive lupus treated by tuberculin by himself in 1896; two years ago, when the patient was last seen, there had been no return.

Hr. Guttman pointed out the good results that had been obtained by tuberculin in tuberculosis of the eyes.

Hr. F. Lesser was of opinion that any remnants of disease would be recognised by injection of tuberculin, and believed that the long continuance of treatment and the expense attending it were not sufficiently balanced by the good cosmetic results.

Hr. E. Lesser, after replying to the different objections, said that it was of importance that the treatment should suffer no interruption.

The *Therap. Monatsch.*, December, 1904, contains an article by Dr. H. Ulrici on

THE NIGHT-SWEATS OF TUBERCULOSIS AND THEIR CURE, ESPECIALLY BY VERONAL.

It was most plausible to take Cornet's view as to the cause of night-sweats, that they were to be looked upon as a symptom of the action of tuberculous toxins. Hr. v. Schrötter properly distinguished between sweats in the initial stage and in severe cases. In cases with fever, there was mostly a connection between fall of temperature and the outbreak of perspiration. In contrast to pneumonic cases, in which the outbreak of sweat brings relief, in feverish phthisical patients it caused extreme discomfort and weakened them to complete exhaustion.

Most medical men were in favour of endeavouring to overcome night-sweats. Salter, however, was an exception; he was of opinion that they should not be suppressed as they excreted tuberculous toxins.

The patient should get accustomed to sleep in a cool room, lightly covered, and with open windows; regular and not too warm baths, or luke-warm or cold rubbings night or morning, or both. Salicyl powder, tannofom dustings, and painting with a 50 per cent. formalin solution. Brehma recommended a quarter of a litre of milk, with seven spoonfuls of cognac.

Of internal medicine the antipyretics did not do much. Atropine was in the front rank: it often did good, but it sometimes failed altogether. After atropine came agaricine in the form of a pill. It also relieves cough, but patients got accustomed to it. Camphoric acid also did good and guaiac-camphol, also camphorate of pyramidon. Of other remedies he only mentions veronal, which in reduced doses is a very active remedy for night-sweats. It was given before bedtime, either dry or in tea, in doses of 0.3 grm. The first dose acted scarcely at all, with the second the night-sweat was generally less; after the third it usually ceased altogether. Sometimes one had to wait longer for the effect. In a few cases the dose had to be raised to 0.6 grm.

When the sweats had ceased the medicine was stopped. Sometimes they did not return, and if they did in some weeks' time the veronal was given again. It was often well to continue the medicine for a while in half doses. It only failed in one case, one of high fever, for which pyramidon had been given in the morning. The profuse sweating was scarcely influenced by the veronal.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, February 12th, 1905.

THE CURE OF CANCER.

SEVERAL years ago, it may be remembered, Professor Adamkiewicz caused a great sensation in Austria by publishing his method of curing cancer. For some time this announcement was received by the profession with a considerable amount of scepticism, but Adamkiewicz was strong in his own opinion that he had made a discovery, and convinced others of his power to heal this irresistible morbid condition. Divisions arose in the profession, and challenges were thrown about till Adamkiewicz was offered a ward in the

Allgemeine Krankenhans to prove to the profession that his method of treatment was a success.

The conditions at first were that the neoplasms were to be selected by other professors of the Faculty, and examined from time to time during the treatment, according to arrangement. It is now over ten years since this arrangement was inaugurated, and still he is groping for a cure. During this period, however, he has given to the world different opinions as to the origin and cause of carcinoma, but little hope of a specific. His ten years' experiments may be condensed into a few of his own assertions that cancer cells have nothing to do with epithelium, but are probably parasitic in origin, and in the form of coccidia, as fresh cancerous tissue contains a very characteristic toxin differing in nature from other neoplasms, sarcoma, &c.

He considers this toxin analogous to that found in the dead body, which was probably produced by the parasite and the cause of death. His presumption is that the parasite is killed by this toxin before death ensues, and suggests that the toxin might be used as an antidote. So far he has been unable to isolate the toxin for specific use, but chemically has declared that it is a salt, trimethyl-oxy-ethyl-ammonium-oxyhydrate. According to his own experiments on carcinoma, this toxin has not proved so efficacious as he at first anticipated, but in its use he obtained another derivative which he considers the specific base—trimethyl-vingtammonium-oxyhydrate. This new derivative he terms "cancroin," which may be cited as the theoretical base of Adamkiewicz's method of treating cancer. The hypothesis is somewhat fantastic, and not yet supported by real facts; indeed, it is challenged by general opinion and long since relegated to oblivion that the parasitic origin is not the correct one. His experiment of implanting carcinoma in the brain of animals has not been supported by any other investigators; besides, the hypothesis of a toxin being similar to that found in the dead body and then extracting a derivative is so unscientific that few will hazard an opinion of its correctness.

One proof which he gives is the reaction with this "cancroin," but Albert and Billroth have both left testimony that this is not uncommon in the history of carcinoma. Again other experiments are related where this "cancroin" has checked the progress of the disease, but in this testimony also we have many records to prove that cancer has its intermissions of pause and improvement, as well as local healing in some cases. Virchow affirmed that local cancer often heals spontaneously, while other observers maintain that months and often years elapse without any visible signs of retrogression. This favoured the "Condurango" cure, which was in great demand some time ago. Again, secondary conditions, such as glands and swellings, have often been found to act favourably on carcinoma by setting up inflammation in its surroundings. He gives examples of injecting "cancroin" into subclavicular glands, after which they softened and disappeared. He has other examples in the axilla and mamma, which, he says, kill the cancer cells and eliminate the mortifying matter after having killed the coccidia. He offers another theory for "cancroin," that it acts as a disinfectant, cleansing the tissues and preventing metastasis.

The Operating Theatres.

GREAT NORTHERN HOSPITAL.

CEREBRAL ABSCESS.—MR. PEYTON BEALE operated on a girl, æt. about 25, who had been admitted under the following circumstances:—She was brought to the hospital by the police, who stated that she had fallen off an omnibus when coming down the steps. She was conscious when picked up, and semi-conscious when admitted, but at the same time unable to give any concise account of the fall. There was no paralysis, the face was flushed, and the right pupil dilated; the pulse became slower and the breathing stertorous.

There was a stellate scalp wound on the left parietal region, but on probing this no fracture or injury to the bone could be detected. As the symptoms of cerebral compression were becoming more and more pronounced, she was trephined at the seat of the scalp wound. On raising the bone the dura mater was found to be normal, but there was no visible pulsation. On incising the dura mater, some clear fluid escaped, coming from the frontal region, and some pieces of blood-clot coming from the temporal region. It was assumed that she had a fractured base, and this was apparently verified by the fact that on the next day she had some blood-stained discharge from the nose. The compression symptoms were relieved by the operation, but three days after it they appeared again with increasing severity, so she was trephined again about two inches in front of the seat of the former operation. From beneath the dura mater there was evacuated about two ounces of pus; the cortical brain substance was semi-fluid, and a great deal of it was washed away by irrigation. After this operation she was again relieved, but the right arm was paralysed, and she was unable to speak—that is to say, to express adequately her thoughts and desires. Mr. Beale said that the case was of interest because it was obvious at the second operation that the girl had a cerebral abscess, which was the result of a suppurating frontal sinus; this, of course, accounted for the discharge from the nose, but no previous history of it could be obtained from the patient's friends. Everything, he said, pointed to a fractured skull as a result of the fall, the symptoms of compression being caused by blood-clot, and it was only when the second operation was performed that it was apparent that the fall was the result of giddiness brought on by a commencing cerebral abscess. The improvement after the first operation was, he considered, merely due to the relief of the tension, the latter being brought about by exudation of fluid prior to the formation of pus. The circumstances of the injury were such that there was no eye-witness to state exactly how it was produced. No doubt, he remarked, the unconsciousness at first was simply due to severe concussion; he did not see how under the circumstances the diagnosis of the actual state of affairs could have been arrived at. He pointed out that the paralysis of the arm and loss of speech were probably due to the destruction of cerebral cortex by the accumulating pus on its surface. The small blood-clots which came from the temporal region at the first trephining might possibly, he thought, have been the result of a small fracture in the temporal bone or possibly to slight laceration of the cerebral cortex in this region as a direct result of the fall, but there was no bleeding from the ear, nor could the injury in any way have produced the abscess which was subsequently found.

ST. PETER'S HOSPITAL.

CASE OF PAPILOMA OF THE BLADDER REMOVED BY SUPRAPUBIC CYSTOTOMY.—MR. SWINFORD EDWARDS operated on a man, æt. about 50, who was very obese, and who had had hæmaturia at times over a space of the last six years. For the last month the urine had been always coloured. Cystoscopy a fortnight previously had revealed a papilloma apparently the size of a walnut growing from the left side of the bladder not far from the left ureteral orifice. Before operating, Mr. Edwards performed cystoscopy with a view of confirming the diagnosis; this he was able to do, and he

demonstrated the growth to several surgeons present. Suprapubic cystotomy was then undertaken, the bladder having been previously washed out and distended with about ten ounces of boracic acid solution. Mr. Edwards drew attention to the enormous amount of fat which he had to cut through before reaching the linea alba. The bladder having been opened the finger was passed down to locate the growth, and Thompson's bladder forceps were applied to the pedicle, which was short and about the size of the little finger. Some difficulty was experienced in this owing to the depth of the growth from the surface caused by the fat parietes. Here manipulation was facilitated by irrigating the bladder through the inlying catheter. This floated up the growth between the jaws of the forceps. The growth was partly wrenched and partly twisted off, and came away whole. The finger could discover no pedicle left, but to make sure that it had been taken off flush with the bladder-wall, a caisson tube was passed in and the operative area explored with electric light from a head lamp. By this means the place whence the tumour had been removed was easily seen. A small piece of jagged mucous membrane was cut away, and to the wound was applied a 20-grain to the ounce solution of nitrate of silver. By this time all hæmorrhage had practically ceased and the operation was completed by the insertion of a large suprapubic drain and a further irrigation through the inlying catheter, which was then, of course, removed. Mr. Edwards said that this appeared a very favourable case, and he thought after the complete operation which had taken place a recurrence would be unlikely, though the surgeon must not forget that papillomata in elderly people were liable to become infiltrated at their bases, which was practically the commencement of a carcinomatous condition; indeed, he said, the next patient he was about to operate on, a man, æt. 60, was a case of a like nature, but which had recurred in the space of six months. It had been a much larger growth than the one he had just removed; like it, it was pedunculated, but the pedicle, which was as large round as a man's thumb, was tough and hardish; indeed, it looked at present, he thought, as if carcinomatous infiltration had then already taken place. The great thing to ensure success in these operations, he considered, was first to get the cases early enough; secondly, to be sure, by taking plenty of time over the operation, that all the papillomatous tissue was removed, and this could best be decided by electric illumination through a caisson tube. The risk of this operation, he pointed out, is but slight if free bladder drainage be assured. He proposed to keep the tube in for three days at the outside, and he anticipated that the patient would leave the hospital with the wound soundly healed within the month.

Society of Apothecaries of London.

CANDIDATES competing for the Gillson Scholarship in Pathology are required to send in their names, with testimonials, by February 28th, to the Secretary.

University of Durham.

The Senate of the University of Durham has decided that German may be offered as an alternative subject for Greek in the Preliminary Examination for medical degrees. This concession will come into force in September, 1906.

REGISTERED FOR TRANSMISSION ABROAD.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, FEBRUARY 15, 1905.

THE METROPOLITAN SUNDAY AND KING EDWARD'S HOSPITAL FUNDS AND THE SMALL HOSPITALS.

In concluding the present series of articles we propose offering a short summary of our main points. The omission of a certain number of the small hospitals from the grants of the Sunday and the King Edwards' Funds conveys to the public an unfavourable impression as to the worthiness and good character of the particular institutions thus omitted. Our discussion has been directed mainly to the analysis of facts, which are admittedly not easy in all instances to obtain but we believe that we have in the main secured substantial accuracy as to principles and to broader features. We mention this because Sir Henry Burdett, who came forward to answer some of our earlier strictures in the columns of the *Hospital*, triumphantly exposed some inaccuracies of detail, while he carefully avoided answering vital questions of principle. Latterly, Sir Henry has ceased to offer even these wavering defensive replies, and in default of his championship it would almost appear as if our criticisms were unanswerable. In any case they have been offered with a sincere belief in the past, present, and future sincerity and whole-heartedness of the two Funds mentioned. The interest taken in them by King Edward and by the Prince of Wales guarantees that their policy will sooner or later be reduced to one of absolute justice and fairness. Meanwhile we venture to suggest, on the evidence that we have been offering to our readers during the past six or eight weeks, that there is much room for improvement in the administration of the Funds with regard to the smaller hospitals. We suggest various reforms as worthy of consideration. First, the constitution of the Council of the Funds, which should, in our opinion, be so broadened as to include representatives of all the small hospitals. Second, a clear statement of reasons for not making a grant to any particular hospital. Third, a right of public

appeal against the decision of the Council in refusing an award. Fourth, a clear statement of principles on which grants are made. Fifth, that a public inquiry be made into the sale of the Royal Orthopædic Hospital and the attitude of the Funds in relation thereto. As things go, chaos reigns in the administration of the Funds. Skin hospitals, as we have shown, are tabooed, except in the case of St. John's Hospital, which is a limited liability company, and strictly speaking not a hospital at all. Eye hospitals are all recognised, especially the Royal City Ophthalmic (formerly Moorfields), which, being bankrupt, receives enormous subsidies of the money of the charitable public for some occult reason best known to the Funds. There is no suggestion that eye hospitals should amalgamate, but the policy of amalgamation is enforced to the bitter end in the case of orthopædic hospitals. The chairman of the Royal Orthopædic Hospital, being a prominent official of the Hospital Sunday Fund, is placed in a false position with regard to amalgamation in that particular instance, inasmuch as the sale of the Royal Orthopædic site has brought an enormous sum to the "National." Another prominent official of the Sunday Fund is chairman of a small hospital for fistula, a specialty that is absolutely superfluous and grotesque, but which nevertheless receives substantial yearly awards. Then, again, the fact that *Truth* has for years together mercilessly exposed the undesirable and questionable practices of any particular institution does not prevent the Funds giving them public money in spite of many grave charges unanswered in the law courts. The relentless rigour of the Funds, indeed, seems to be reserved for a few hospitals that are poor and humble, and do not happen to have powerful friends at court. In this respect they share to some extent the position of the poor population for whom this vast wealth of charity is subscribed, but who find themselves to a great extent shouldered out of their birthright by the competition of well-to-do middle-class persons who can perfectly well afford to pay a private medical attendant. The result is that the average general practitioner is forced into a harder and harder struggle to gain a living. In the long run this means an inferior race of medical men available for the service of the nation. There is a great and legitimate field open to the Funds in the regulation of hospital relief. Instead of pouring money for ever into a bottomless pit of indiscriminate alms-giving, let them watch the outgoings, and thereby preserve both the self-respect of the average citizen of moderate means and the welfare of a noble and humane profession. There are enormous material disbursements involved in the administration of the medical charities of the United Kingdom. Contractors, landlords, merchants, lawyers, officials and tradesmen grow rich from being connected with them, whilst philanthropists gain social eminence and titles from the same source: even hospital journalists extract fortunes therefrom. The only persons to suffer

are the general practitioners, who are deprived of an immeasurable amount of legitimate income by the unfair competition of the medical charities. We commend these things to the consideration of the King and the Prince of Wales as matters vital to the future successful constitution and policy of the King Edward's and the Sunday Metropolitan Hospital Funds.

TRYPANOSOMIASIS.

BOTH to the man of science and to the practical student of clinical medicine, the subject of trypanosomiasis is at present one of much interest. Our knowledge of the condition is altogether modern, and has increased so rapidly within the last few years that it is impossible at present to judge to what lengths it may go in the future. The trypanosome is closely allied to the malarial organism in its life history and nature, and the clinical condition to which it gives rise presents many similarities to malaria. This condition, speaking quite generally, as regards both man and the lower animals, includes irregular paroxysms of fever, adenoid enlargements, anæmia, and very often œdema, erythema, and other indications of the presence of toxins in the blood. Up to the present, several different types of trypanosomes have been discovered in relation to different morbid processes. Of these the earliest to be discovered was that which is parasitic in the rat. It is said to be very widely diffused, and to be practically harmless, as no definite pathology has been associated with it. It is believed to be transmitted from animal to animal by the flea. Much more important is the tsetse disease, which has been long known as endemic in parts of Central Africa; its connection with trypanosomal infection, however, has only been recently discovered. Unlike trypanosomiasis of rats, the tsetse disease does not confine itself to one species of animals, but affects all the domestic animals with impartiality—the horse, ass, ox, sheep, goat, and dog. There is no authentic record of the infection of man. There are other diseases of animals occurring in different parts of the world, each due to a different type of trypanosome, as, for instance, *surra*, first noticed in India, *mal de cadava*, endemic in South America, and a widespread disease of cattle in the Transvaal. It is only within the last two or three years that the trypanosome has been discovered in human blood. It had been observed by Dutton, Baker, Manson, and others as occurring in various parts of the tropical regions of Africa, but real importance has only accrued to it by reason of its connection with sleeping sickness. Although Castellani observed the trypanosome in a few cases of sleeping sickness, it is to Bruce that we are indebted for any real knowledge of the facts. It is not to be supposed that sleeping sickness is the immediate result of the presence of the parasite in the blood, for it may be present in the blood for many years without the development of sleeping sickness. It is most probable that the group of symptoms known

under that name only appears when the parasite has established itself in the cerebro-spinal fluid. All the varieties of trypanosomiasis which have been described, with the exception of the disease in rats, probably owe their transmission to some fly of the genus *Glossina*. It is probable that the reason why the disease does not spread outside the tropics is that the necessary vehicle for transmission is not to be found.

SOCIETY FOR PROMOTION OF TRAINING OF NURSES.

A NEW and interesting turn has been given to the affairs of the nursing profession by an application just made to the Board of Trade to incorporate a Society for Promoting the Higher Education and Training of Nurses. Baffled in their attempt to obtain statutory powers for the control of qualified nurses, those who were directing the movement to that end have taken this fresh step with a view to getting together an organisation which will be able, by moral pressure, to accomplish what Parliament practically refused them legal right to do. We think ourselves, and we said so at the time, that the State registration of nurses would, if adequately hedged about with safeguards against abuse, have worked for the good of nurses, patients, and doctors. But the project was not well engineered, and as it made its appearance in two Bills introduced last session, there is no doubt that the bulk of the medical profession was opposed to it, and that opposition was strong enough to scotch it for the time being. The promoters of this legislation were wise to recognise the inevitable, and to decide not to pursue an object which was clearly not to be obtained by a *coup de main*; in face of the hostility of a large section of the medical profession it would have been mere waste of time and money to have brought forward similar Bills this session. They have, therefore, been well advised to desist from their efforts, and to direct their energies to reform of the nursing world from within. Whether the inauguration of the present Society is the best way of accomplishing this it is yet too early to say, but it may be remarked that, as a rule, precipitancy is generally the surest way of delaying a project for which a strong and unanimous demand does not exist among the parties chiefly concerned. The objects of the Society as set forth in their memorandum of association are to promote the higher education and training of nurses, to promote unity of curriculum in the training of persons intended for the nursing profession, to recognise approved nursing schools, to grant certificates of proficiency to persons who pass prescribed examinations, to establish a register of nurses, and to have power to remove names from the same. It is obvious at once that this movement aims at gaining by a flank manœuvre what it failed to win by a frontal assault, for if the Society succeeds in obtaining these powers it will in time practically control the whole course of education and subsequent dis-

cipline of the nursing profession. It is, then, necessary to inquire very carefully into the *personnel* of the promoters and the methods by which they propose to work. Now, we say emphatically that any movement that seeks to emancipate the nursing profession from due subordination to the medical profession is working on radically vicious lines. This is no question of individual liberty, but one of the essence of the efficiency of nursing. However capable, intelligent and accomplished a nurse may be, she cannot act in a plane independently of the medical man; the prime test of her fitness is her power of taking for granted the fact of complete subordination to authority. It is no more possible to free nurses from the control of doctors than it is to free privates in the Army from the control of their officers; one class is trained to command and the other to obey, and no good will ever come of trying to confuse that plain fundamental issue. This being so, we turn to the constitution of the proposed council of management of the projected Society, and we notice that in a council of twelve three seats only are reserved for men, and of these only two are to be necessarily medical men. The remaining nine seats are to be filled by women nurses. In other words, the advice of medical men will be received and listened to, but the control of their own affairs will be entirely in the hands of the women nurses in virtue of their overpowering majority on the council. To our minds this alone vitiates the whole scheme, and unless the constitution be amended to give a complete reversal to these proportions, we can assure the promoters of the Society that they will find no less vigorous opposition from the medical profession than they encountered before the Select Committee last session. For be it remembered that the council of management is not only laying down the curriculum to be followed by nurses, but to prescribe and control the examinations that qualify them for registration, and if it be thought that medical men in their professional capacity will tamely submit to the direction of their subordinates, we can only say that a stupendous lack of the sense of proprieties must animate the framers of the scheme. It is much as if a coachman were compelled to take a couple of horses with him on the box to tell him how he was to drive the remainder of the team. But this proposal is so ridiculous as to be hardly worthy of serious consideration. To persist in it would be absolutely fatal to the whole scheme. Uniformity in curriculum and examination is a worthy object for nurses to seek, and a proportionate representation in the management of their internal affairs a legitimate aspiration; we believe that both these changes—together with the establishment of a register—would be beneficial in the long run to the nursing world. The steps by which they are to be obtained must, however, be clearly approved of by both medical and nursing professions, and agreed upon by their representatives. It will be highly detrimental to the interest of the

nurses if they allow themselves to be rushed or over-persuaded by any one clique or section of advisers. Ourselves, we should counsel them, in their own interest, to act only in conjunction with the medical profession.

Notes on Current Topics.

The Cause of Appendicitis.

At the present moment the public mind is all agog on the subject of appendicitis. Every medical practitioner in the United Kingdom is assailed many times a day with questions as to the cause of the malady. What, indeed? Certainly, in the majority of cases, not grape-stones, nor hurried eating, nor—ye gods!—Hungarian bitter aperient waters. The actual causes are probably complex, inasmuch as inflammation is a symptom that may be set up by a score of different conditions. Broadly speaking, anything that seriously disturbs the intestinal well-being predisposes to appendicitis—that is to say, to the inflammation of a portion of the bowel invaded by one or more harmful kinds of bacteria. In this light it is easy to understand the likelihood of influenza being now and then a cause of appendicitis, as suggested by Mr. A. T. Norton, the well-known surgeon, in our correspondence columns. It is a familiar fact that in some forms of influenza the brunt of the mischief falls upon the gastrointestinal tract. In any case, the theory is worthy of careful attention, even though it add one more to the list of probable causes of a fashionable but disastrous malady.

Mortality in the Profession in America.

OUR contemporary, the *Journal of the American Medical Association*, published lately a series of figures relating to the deaths occurring among practitioners of medicine in the United States and Canada during the year 1904. The figures are not based on precise statistics, but nevertheless present many points of interest. The average age at death among those recorded was over sixty years—not an unpromising outlook—while the average length of practice was over thirty years. Out of about twelve hundred deaths of which the causes were recorded, the disease responsible for the greatest number was heart disease, with 205. Cerebral hæmorrhage caused 179, pneumonia, 172; and nephritis, 91. Tuberculosis has a nearly equal mortality, 90; and of other diseases, cancer, typhoid, septicæmia, diabetes, gastritis, appendicitis, meningitis, bronchitis, insanity, hæmorrhage, peritonitis, asthma, influenza, tabes, paresis, rheumatism, gangrene, erysipelas, diphtheria, and scarlet fever follow in order. The low mortality from infective diseases, apart from tubercle, is very remarkable, considering the exposure to which medical men are subject. The high number of deaths due to pneumonia is, however, very striking. In addition to such natural causes, 143 physicians met violent deaths. Of these 95 deaths were accidental, 36 suicidal, and 12 due to murder. The number of suicides is remarkably

large, and probably much in excess of a corresponding figure in this country. In spite, however, of the dangers surrounding their path, we are glad to see that three physicians passed the age of one hundred.

Typhoid Epidemic at Lincoln.

AN epidemic of typhoid is raging at Lincoln and already has attained dimensions which give cause for grave alarm to the inhabitants of that city. The fever hospital is full and several public halls are being used for the accommodation of poor patients who cannot be properly looked after in their own homes. Fortunately a Local Government Board inspector is on the spot to inquire into the cause of the outbreak and advise, and a temporary medical officer is in charge of the arrangements in the absence of the medical officer of health through illness. It remains to be seen to what extent the epidemic will yet spread, but at the time of writing 345 cases have already been notified. Whatever the final results will be it is obvious that the prosperity of the city must be severely affected, the inhabitants burdened with much expense, and many lose their lives. For this lamentable state of affairs the residents in the cathedral city have only themselves and their elected representatives to thank. There seems to be little or no doubt that the outbreak was caused by pollution of the city water supply, which is derived from the Witham River and is under the control of the Waterworks Committee of the Corporation. Twenty years ago the medical officer of health reported to the Corporation that the Witham was a dangerous source whence to derive the domestic water supply of the town, and seven years ago the Lincoln Medical Society forwarded a resolution to the Council to the same effect. In the letter containing the resolution the Society's secretary (Dr. Carling) pointed out that not only was the water of the Witham open to pollution from many sources, but that it actually received the sewage effluent from the Bracebridge Asylum, in which institution cases of typhoid were then occurring. The clerk to the sanitary authority replied that in the opinion of his committee the word pollution was not one that could be justly used with reference to the Corporation's water, an opinion that was not affected by Dr. Carling's reply that the addition of a sewage effluent to drinking water was generally regarded as pollution. Retribution for their irresponsible folly has waited some time before falling on the heads of the authorities; it is only to be hoped that their obstinacy and ineptitude may serve as a warning to others who decline to take the advice of experts in matters affecting their own speciality.

Honour for a Dublin Physician.

WE learn that Sir Francis Cruise, one of the veterans of Dublin medical practice, has received an unusual honour in that he has been appointed by His Holiness Pope Pius X a Knight of the Order of St. Gregory the Great, and has received

through the hands of Dr. Walsh, Archbishop of Dublin, the Star of that Order. This unwonted honour is the recognition on the part of His Holiness of the life-long study Sir Francis Cruise has devoted to the life and works of Thomas à Kempis. Sir Francis' study of the authorship of the great classic, "The Imitation of Christ," has been translated into most modern languages, and is generally recognised as the most authoritative statement on the subject. It is an interesting fact that the municipality of Kempen, to show their appreciation of Sir Francis' devotion to their great townsman, have called one of their principal streets "Cruise Street." Quite recently, Sir Francis has published an English translation of the great work itself.

Kuropatkin's Illness.

CHARITY hardly covers so many sins as does sickness. Sickness is the only omnivalent excuse for everything—from not going to church to being beaten in a campaign—and very liberally some persons avail themselves of the privilege of pleading it as a pretext. The Sultan achieved an enviable notoriety for breaking down in health whenever it was particularly desirable that he should give a definite answer to representations made to him, and other equally and less distinguished persons have frequently had convenient seizures at uncomfortable junctures. Of Admiral Rojdestvensky we have not yet heard that he suffered from night-blindness or agoraphobia at the time of the Dogger Bank incident, but it would have made a more dignified defence than a plea of torpedo-boat hallucinations. The Pyrrhic victories of his military *confrère*, however, seem to demand an explanation in illness, and surely enough the St. Petersburg correspondent of the *Petit Journal* has risen to the occasion. "General Kuropatkin's return," he telegraphs, "is practically decided upon. He is suffering from cerebral anæmia." For euphemistic periphrases we venture to think that "cerebral anæmia" would be hard to beat. It deserves to rank in happiness of expression with the phrase of a contemporary which described an old lady as "expiring of emotion" on the return of a long-lost son. The brain, we know, like other organs, attains its maximum functional activity in the presence of a rich supply of blood; if that supply be withheld, we presume, it deteriorates. "Cerebral anæmia" thus would account for many strange vagaries and erratic perturbations in the conduct of the sufferer, and might therefore be accepted, we take it, as synonymous with the condition that the irreverent schoolboy would designate in his more homely language as "off his rocker" or "balmy on the crumpet."

Derma Rays.

A PAPER was read and a demonstration given at the Röntgen Society on the 2nd of this month of a new method of treatment of cutaneous diseases by light. The particular rays employed are called the "derma" rays, and they are said to have superseded Röntgen rays to a great extent in America

and on the Continent. It is claimed for these rays that they inflict far less damage on healthy tissues and cause more rapid nutritional changes in unhealthy tissues than X-rays do, and that malignant disease and chronic dermatitis never occur as the result of their action. The derma rays, however, do not seem to be able to give so good a photographic result in the case of injuries to bones. This and much other interesting information, embroidered with the usual reporter's epithets, we glean—not from the pages of a medical contemporary but from those of the *Weekly Dispatch*. We can hardly believe that the readers of this excellent journal are so far ahead of the medical profession in the power of forming a judgment on scientific matters that they should be thought worthy of having these tit-bits of therapeutic information served up for their delectation when the Röntgen Society itself decided to adjourn discussion on the paper presented them till they had had time to read it in print. But perhaps we are too much out of the world to understand the new order of affairs in medical matters—an order which seems to be the converse of what common sense would dictate.

Labour Observed in an Isolated Uterus.

A SERIES of experiments of great physiological and pharmacological importance are reported by Kurdinowsky, who has been studying the uterus of rabbits under varying conditions. He anaesthetised the animals forming the subject of his experiments, and having washed out all blood from the uterus by injecting Locke's fluid into the aorta, removed the organs to a chamber specially prepared and kept moist. The unimpregnated uterus was found to be capable of contracting in response to stimuli for three days after removal, and these contractions followed a definite course which could be recorded by the inscription of a curve. The most interesting of his experiments, however, were those carried out on pregnant uteri, for in these Kurdinowsky was able to follow the process of labour throughout. Contractions were seen to start in the cornua and continue till the fœtus in each cornua was completely separated from the walls, when they were each pushed through the uterine wall at the same moment. Once in the uterus the fœtus is acted on by ring-like contractions of the muscular walls, the Fallopian tube taking an active share in the contraction till the fœtus enters the vagina. Thus it was apparent that the whole act of labour is, or can be, carried out without reference to the central nervous system. Electrical stimulus affected the contractions but little, though chemical and thermic applications were capable of throwing the organ into tetanic spasms. Thus ergot acted well in producing muscular contraction without producing any effect on the vessels; alcohol and chloral, however, did not seem to make much difference. The remarkable feature was the potency of adrenalin, even in high dilutions, in bringing on

uterine action, and the suggestion is that in this drug we have an ecboic of more than ordinary value.

A Valuable Disease.

FORTUNATELY for medical men the majority of sufferers in this world wish to be rid of their diseases and (in many cases) are prepared to pay for means by which this consummation may be attained. An exception is of sufficient rarity to warrant notice. A case of ankylostomiasis was reported last week to the Lancashire County Council, and with commendable promptitude steps were taken to isolate and treat the case before the infection could spread. The Health Committee not having any legal power in the matter, resorted to bribery and offered the man £1 a week if he would remain in the Wigan Hospital for treatment, and later on even larger sums if he would undergo treatment in Manchester. The man, however, was not to be beguiled by filthy lucre to part with so rare a treasure, and his mother declared that if her son was suffering from such a valuable disease he had better keep it. So in this happy England an ignorant miner is allowed to rove freely spreading a noisome and foreign pest among his fellow-countrymen without let or hindrance. There are certain prices to pay for the privilege of wearing the Phrygian cap.

A New Cancer Serum.

WHILE Paris is still busy discussing Doyen's cancer serum, there comes news from America of the discovery of a quite different serum reputed to be a cure for cancer. It is stated that at the Gratwick Pathological Laboratory at Buffalo, as the result of experiments on mice, a serum has been prepared which has a curative effect on cancerous mice. Certain mice are said to have been inoculated with cancer, and, though some of them died, others recovered. It was suggested that the blood of the latter might possess certain antitoxic qualities, and experiment supported the suggestion. The experimenters claim that the injection of serum from the animals that had recovered into the circulation of animals still suffering was followed by arrest of growth of the tumours, or, in less advanced cases, by actual disappearance of the tumours. There is, so far, no report of any experiments on man, so that it is too soon to express any hope as to the result of the investigations at Buffalo. If a cure results, then the ancient proverb of the mountain's travail will have to be reversed. There is, however, another old saying regarding the plans of mice and men which it may be just as well to keep in mind where so baffling a malady as cancer is concerned.

A "Domicilium" or Air Chamber in 1677.

TOWARDS the end of the 17th century, Dr. Nathaniel Henshaw, realising the hardships of foreign travel for the invalid rich, and its impossibilities for the sick poor, sought to solve the difficulties by the construction of a *Domicilium* or Fresh-Air-at-Home apartment. Clearly the air would

not be fresh or pure everywhere, so the modern sanatorium system would not work. Therefore, an air-tight compartment, with door and windows closely fitting, was to be made, and "a very large pair of organ-bellows, the nose of them exactly joyined to a copper pipe must pass through the wall of the room and have a valve opening outward exactly fitted to it, which pipe must likewise have another valve to open inward, one valve at a time being used; . . . working gently with the bellows you may either charge or discharge the air-chamber," regulating the air by means of a weather glass, "and a person may have such air as were not otherwise found but on the Pike of Teneriff, or make it such as is not again to be found upon the face of the whole habitable world." Huge cupping-glasses are also advised to make "powerful revulsions so necessary in some diseases" and a "long sitting-swing, by the use of which the abdominal muscles are gently compressed and the chyle more nimbly protruded from the intestines forward to mingle with the blood." An "able physician," we read, is necessary to judge whether the patient should stay in the *domicilium* during the whole course of acute disease or only spend part of the day there. This little treatise was printed by command of the Royal Society in 1677. In various guises the pure air chamber has cropped up again and again in the treatment of consumption and other diseases. A contrivance of this kind was described in our own columns within the last twelve months.

School Hygiene.

THE increased interest taken by health authorities, and, indeed, by the public generally, is a conspicuous feature in the practical application of science to the things of everyday life. If the recent scare about the physical deterioration of the nation has done nothing more than to awaken school-boards and teachers throughout the land to a sense of their grave responsibility in connection with the health of their scholars, it will have accomplished its mission. The importance of the "gospel of the body" cannot be over-estimated when it is remembered that the building up of the national physique is begun in the class-room. If the cubic space of this be miserably cramped, the atmosphere foul, the ventilation and lighting arrangements inadequate, and physical exercises be conspicuous by their absence, how can young and growing bodies be expected to attain their fullest development? There is a danger, on the other hand, lest practical hygiene be narrowed in its application by too many conflicting theories or by too elaborate details. The recent conference upon the subject held at the University of London in connection with the Royal Sanitary Institute was essentially practical in character, only those questions being discussed which were of really vital interest to school-children as a class and as individuals. The idea that there should be no lessons after school hours in the case of younger scholars, put forward by Dr. Clement Dukes, is excellent,

for surely the tendency to acquire knowledge solely through the aid of books, with the consequent inducement to cramming, is already playing sufficient havoc among delicate and nervous children. The abolition of several of the examinations would also be a step in the right direction. The need for systematic inspection of school-children by medical men was one of the motions formally adopted by the conference.

Water-Drinking in Disease.

THE question as to whether pure water should be allowed in sickness, and if so, in what quantity, may be approached from two entirely different standpoints. In the first place, in many diseases the organs and tissues of the body seem to cry out, almost, for an abundant supply of water, especially when the processes of internal combustion are proceeding at a greater rate than the normal, as in the acute specific fevers. In the case of young children the natural water-seeking tendency is only too often needlessly checked, for, in moderation, it cannot but serve a good purpose. The craving for fluid of some kind in diabetic states is quite another matter, and limitation here is seldom wise. On the other hand, the treatment of diseases by the so-called "water-cure" has reached an extreme pitch in modern times. Aerated or mineral waters, of natural or artificial production, are recommended for the most varied disorders in order to "eliminate toxic materials from the system," while frequent ablutions in divers medicated baths must on no account be omitted if the prescription of the ardent hydro-therapist is to have good effect. Dr. Morris Manges, (a) of New York, considers that the abuse of water-drinking is most often seen in cases of chronic nephritis, and he believes that many a compensated heart is shattered at Carlsbad, or some other popular health resort! The researches of Baruch show that water in small quantities, at the ordinary temperature, has very little effect upon the blood-pressure. It is otherwise when arterial pressure is increased or when arterio-sclerosis prevails. Many authorities have observed nothing but good results from the restriction of fluids in cases of granular kidney. It is of the highest importance to ascertain the condition of the circulation first, before directing the patient to consume large quantities of water, pure or medicated.

Dr. Freyberger as Coroner's General Medical Expert.

THE Westminster Coroner, Mr. Troutbeck, appears to have resolved to place the evidence of his court pathologist, Dr. Freyberger, over that of the whole medical profession in his district, be the case of a general medical or of a purely pathological nature. An illustration of that gratuitously offensive position may be taken from an inquest held last week at Battersea on the body of a woman who died from puerperal septicæmia. Deceased was attended by midwives from a

maternity home under the direction of a lady doctor, whose qualification was stated to be of seven months standing. With the rashness sometimes associated with the newly-fledged diplomate, she appears to have rejected the advice of a consultant to notify the case to the medical officer of health as one of puerperal fever. The lady in question cannot expect much sympathy in her subsequent exposure to "severe censure" in a public court. Now, it will be well to ask the ratepayers and the Town Councils of the districts included within Mr. Coroner Troutbeck's jurisdiction how long this needless waste of public money and this injurious degradation of a humane and liberal profession is to go on in their midst. The evidence of the consultant medical man as to the condition of the deceased, which he diagnosed during life, was clearly enough to establish the cause of death beyond a doubt, in the above case. If necessary, he could have performed the *post-mortem* examination, and there was no more need for the "skilled" services of Dr. Freyberger at a fee of two guineas than there was of an official from the British Museum, or any other superfluous witness. Where is the Lord Chancellor and where the boasted enlightenment and economy of the London County Council?

Kitasato on Bovine Tuberculosis.

ONE of the most interesting contributions to the controversy roused by Koch in 1901 as to the relation between human and bovine tuberculosis is that made by the distinguished Japanese pathologist, Kitasato. His observations are specially important, since the conditions governing possible infection of man by the ox are quite different in Japan from what we are used to in this country. The native Japanese cattle are entirely free from tubercle, and even to experimental inoculation present a remarkable immunity. Imported or mixed breeds, however, show no such freedom from disease. Human tuberculosis, according to Kitasato, is quite as common in Japan as in these countries, and in this he is borne out by the experience of others. Infection by milk can, however, take but a small part in the production of the disease, since even were the cows affected, milk is hardly used at all as a beverage. The average daily consumption of milk in Japan is stated to be only three cubic centimetres—a small teaspoonful—per head. Kitasato's conclusions, therefore, while altogether negative, furnish a strong support to Koch's views, and are at variance with von Behring's doctrine that the starting-point of most tuberculous disease is an intestinal infection, suffered during childhood, from the ingestion of milk.

PERSONAL.

SIR THOMAS MILES, President-elect of the Leinster Branch of the British Medical Association, will deliver the Annual Address at the general meeting of the branch to be held on the 25th inst. at the Royal College of Physicians, Kildare Street.

THE ceremony of presenting the Honorary Fellowship

(a) *New York Medical Journal*, January 21st, 1905.

of the Royal College of Surgeons in Ireland to the Provosts of Trinity College, which was to have taken place on Saturday last, was unavoidably postponed owing to the indisposition of His Excellency, the Earl of Dudley, who was to have honoured the ceremony by his presence.

AN action in which £2,000 damages were claimed was brought during the past week by a farmer against Dr. Patrick Helion Fox, formerly a Major in the Royal Army Medical Corps, for the loss of his arm, occasioned by Dr. Fox firing at him and shooting him. Dr. Fox's evidence went to show that the plaintiff and others had assumed a threatening attitude in consequence of an agrarian dispute, and that he was compelled to fire in self-protection. The plaintiff stated that he had been as quiet on the occasion as he was that day in Court. The jury disagreed, and were discharged.

As a representative of science and higher education, Sir Michael Foster has consented to offer himself for re-election to the next Parliament as member for the University of London. If re-elected he will take his seat as a member of the Liberal party. A committee, with Sir Thomas Barlow as chairman, has been formed to promote his election.

DR. CLIVE RIVIERE, 19 Devonshire Street, W., and Dr. D'Arcy Power, 10A Chandos Street, W., are acting as hon. secretaries for the English branch of the Fifteenth International Medical Congress at Lisbon on April 19th.

SIR JOHN BATTY TUKE will deliver the Presidential Address at the annual general meeting of the Neurological Society of the United Kingdom, to be held at 11 Chandos Street, W., on February 16th, at 8.30 p.m. The subject of the address is the relation of the lunacy laws to the treatment of insanity.

PARIS next May will see her leading doctors gathered at a congress "for the repression of illegal medical practice," which is to be held under the presidency of Professor Brouardel. Maitre Bruno-Dubron, LL.D., will deal with the illegal practice of medicine by ministers of religion, teachers, benevolent associations, and so on.

A MEETING of the Pharmaceutical Society will be held at 17 Bloomsbury Square, W.C., on Tuesday next, when Mr. W. S. Glyn-Jones will open a discussion on a comparison of methods in the United States and in England to secure the purity of foods and drugs. The chair will be taken at 8 p.m., by the President.

THE German Balneological Society will hold its twenty-sixth meeting at Berlin on March 9th; Professor Liebreich will take the chair, and Professors Heuber, Ewald, Eulenberg, and others will read papers.

Special Correspondence.

[FROM OUR OWN CORRESPONDENTS.]

SCOTLAND.

The Monson Lectures.—The last of the series of lectures was delivered by Dr. John Macpherson in the Royal College of Physicians on February 3rd. First of all, considering the prognosis, the lecturer said that under the existing system it was not very favourable. Of eleven persons attacked by insanity, four die sooner or later during the attack, while of the six who recover not more than two remain well during the rest of their lives; the other four sustain subsequent attacks during which three of them die. A great deal more might be done, however, to promote recovery from the confusional insanities—the new and acute cases—than is done at present. These, being due to a complication by toxæmia, ought to be treated carefully from the very onset, the destruction of the delicate

cortical cells being so rapid that time was everything. The only way in which our knowledge of these diseases can be advanced is by their study and treatment by hospitalising patients exactly in the same way as if they were suffering from any other acute illness. At present a patient with any acute mental affliction must be certified and sent to an asylum (unless he can be treated at home), without there being any opportunity of examining, observing, and treating him at once in the same way as if he had pneumonia or a broken leg. Framed as they were to safeguard the liberty of the subject, the lunacy laws must in this particular be retained, but we have so far outgrown these laws in this respect, that they no longer secure the patient's liberty, but compel him to be certified before he can obtain relief. In every large city, therefore, hospital wards, and an out-patient department for the care of cases of acute insanity should be opened; these should be open to the public and to students, like any other wards. Such clinics already exist in Germany, Italy, Austria, and Switzerland, and some parts of America; their absence in this country is an instance of passive cruelty which is a blot on our civilisation. The lecturer then took up the need for disencumbering asylums of harmless chronic cases, and treating them in families or on the colony system. Next came the question of the best way of dealing with weak-minded offenders, epileptics, and inebriates. In 1903, 1,300 persons convicted of petty offences in Scotland had upwards of fifty previous convictions against them. This standard was taken as presumptive evidence of mental unsoundness, and Dr. Crawford Dunlop was engaged on the laborious task of examining individually into the mental condition of these frequent offenders. The lecturer gave illustrations of the mental state of these persons, and urged that punishment was useless and reform, in most cases, impossible. The comparative failure of the Inebriates Act was instanced as an example of a mistaken line of reform. In the interests of decency and order, as well as for the welfare of the subjects, inebriates ought to be judicially committed on indeterminate sentences to State institutions, as far as possible under medical management, and not in any way penal. They should be under the lunacy authorities, just as asylums are, the modern asylum of the "village" type being the most suitable institution for their detention, combining, as it does, the advantages of the hospital system and labour colony. He also appealed for the establishment of a national epileptic institution on the lines of the Bielefeld Colony, there being at present no provision in Scotland for the treatment of epileptics except ordinary asylums, which are in too many instances unsuitable for the purpose.

Edinburgh University Honorary Degrees.—Among those on whom the degree of LL.D. is to be conferred at the spring graduation ceremony are William Watson Cheyne, F.R.S., Sir Arthur Conan Doyle, M.D., John Hughlings Jackson, F.R.S., William Keen, M.D., Professor of Surgery, Jefferson Medical College, Philadelphia, and Augustus Walker, M.D., F.R.S.

Glasgow Medico-Chirurgical Society.—An unusually large attendance of members of this Society met in the Faculty Hall, 242 St. Vincent Street, on the evening of Friday, the 3rd inst., when a discussion took place on enteric fever. It was opened by Dr. A. R. Ferguson, on the pathogenesis of the disease, followed by Dr. R. M. Buchanan, City Bacteriologist, on the agglutination test. He preferred to call it by that name, rather than by that of Widal's test, as he thought undue credit had been given to Widal in connection with the serum test, others having a prior claim. In the city laboratory at first the dilution of the blood was one in ten, and the time allowed for the test was half an hour. Experience had now shown, however, that better results were obtained by a dilution of one in fifty, with a time limit of two hours. While some physicians were disposed to minimise the value of the test, he was quite sure it was a very important aid in assisting the medical man in arriving at a correct

diagnosis in many cases of enteric fever, where the other symptoms were not quite pronounced. He asked for complete sympathy between the physician in attendance upon cases of supposed typhoid fever and the bacteriologist in his examination of the blood. Dr. John Brownlee, of Belvidere Hospital, discussed the subject of abortive cases of enteric fever. He mentioned the fact that in the enteric wards of the hospital many of the nurses suffered from attacks of febricula, so in the scarlet fever wards they suffered from sore throats, and again in the measles wards the nurses sometimes were attacked with sore eyes. He urged the need for close attention to the milk supply where there were perhaps several cases in a family, one attacked with diarrhoea and another with a febricula, of two or three days' duration, as such cases in being overlooked were the cause often of enteric spreading not only through a family or tenement, but being more widespread, as the urine may be a means of conveying the infection. Dr. T. K. Dalziel discussed the surgical aspect of enteric fever. He stated that the operation for perforation of the bowel had been performed by himself and his colleague, Dr. MacRae, fifty-seven times in cases of enteric fever. He claimed that he was the first to perform the operation in Glasgow, and he believed he was also the first in Scotland. The perforation was found in the great majority of cases in the small intestine within a comparatively short distance of the ileo-cæcal valve. In only one case was perforation found in the colon. While in Glasgow the number of cases following the operation would not compare favourably with the American statistics, which were placed as high as 40 per cent., it must be remembered that the type of the disease in America was apparently of a much milder character; still the number of cases in the Glasgow hospitals were such as to warrant the operation in all cases of perforation, as then many lives would be saved, where without operation the inevitable result was rapid death. Dr. MacRae discussed the diagnosis of peritonitis in enteric fever, referring more particularly to the symptoms indicating perforation, the fall in temperature and pulse, with a quick rise in pulse, and more especially the facies, which was very characteristic in the great majority of cases, and was quite readily recognised by doctors and nurses alike.

BELFAST.

The Destruction of Rubbish.—Since last week's notes were written more information has come to light about the destructor, to which reference has several times been made in this column. The destructor is question was erected by the Belfast Corporation several years ago at a very considerable cost, though those who had gone into the question of the destruction of rubbish by heat predicted from the first that it could never do anything like what was promised of it. In spite of all efforts by independent members of the Corporation, the details of its working could not be discovered, but were kept a close secret. It was plain, however, to all who saw the resulting ashes being carted away from it that it did no more than toast the rubbish, and though it was said that it developed quite enough heat to destroy all germ life, it was doubtful if it did more than warm it into renewed activity. It has now transpired that there has been no work done by the destructor for some three months, a fact of which even the chairman of the Public Health Committee, Dr. King Kerr, seems to have been ignorant. The serious side of the business is that during all this time small-pox has been prevalent in the city, and all infectious material from houses where cases occurred was supposed to be destroyed at once in the destructor. What became of all this material has not yet transpired, but it is known that other infectious material carted off "to the destructor," as was said, was in reality dumped down on waste ground in the outskirts of the city for rag-men to pick over, and for children to play in! Clearly it is one of those cases where someone ought to be hanged.

ROYAL COLLEGE OF SURGEONS IN ENGLAND.

An ordinary meeting of the Council was held at the Royal College of Surgeons on Thursday, the 9th inst. Mr. John Tweedy, President, in the chair.

The death of Mr. Luther Holden, past President of the College, was reported, and a vote of condolence expressing sympathy with Mrs. Holden, and appreciation of Mr. Holden's services to the College, was adopted.

Diplomas of membership were issued to ninety nine candidates who, having passed the required examinations and conformed to the bye-laws, were admitted members of the College. Nine diplomas in dental surgery, and seventeen diplomas in public health (granted jointly with the Royal College of Physicians) were also issued.

Mr. W. H. A. Jacobson, M.Ch.Oxon, F.R.C.S., surgeon to Guy's Hospital, was re-elected and Mr. Bilton Pollard, M.B.Lond., F.R.C.S., was elected to the Court of Examiners.

Mr. Thomas Bryant, F.R.C.S., was re-elected the representative of the College on the Council of Queen Victoria's Jubilee Institute for Nurses.

The following motion, moved by Mr. Makins, and seconded by Mr. Bowlby, was carried: "That a committee be appointed to consider and report upon the practicability of the institution by the College of a school for the teaching of the early and intermediate subjects of the medical curriculum and of advanced pathology." A committee of eleven members of the Council was thereupon appointed.

Mr. J. Ward Cousins, F.R.C.S., was re-elected to represent the College on the Central Midwives Board.

A letter was read from the President of the Fifteenth International Medical Congress, to be held at Lisbon from April 19th to April 26th, 1906, asking the College to send a representative to the Congress. It was decided to reply that the Council would send a representative of the College.

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

IS INFLUENZA THE CAUSE OF APPENDICITIS?

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Appendicitis is now becoming a so serious and so constant disease, and is attended with such fatal results, that it behoves the profession to ascertain why this disease should have so recently come upon us, and if there be any means of preventing it. I say "recently come upon us" because, if we look back for, say, five-and-twenty or thirty years, a date before the Listerian method of operating was introduced, we then recognised cases of appendicitis and of pericolicitis—certainly very few in number compared with the present time—though we were cautious in operating on them. I am inclined to think that influenza may be the cause of this terrible increase. I used to point out to my students in the wards that influenza had certain characteristics resembling more of septicaemia, inasmuch as it so frequently resulted in indurations, and abscesses of connective tissue, of glands, &c. In the early times of influenza, cases came under my care of chronic indurations in the neck, with aching pain, and of such stony hardness that even malignant disease could with difficulty be excluded in the diagnosis. These indurations ultimately become absorbed under treatment or suppurated. They were unmistakably sequelæ of influenza.

I have recollections of very numerous cases of influenza followed for months by a septicaemic chart, say, 90° in the morning, and 101° at night, many without objective signs. In every one of these I was able to prognosticate later suppuration, thoracic or abdominal. Among them were cases of pericolicitis and indurations of the abdominal wall, which, of course, were readily diagnosed.

Now, I would suggest to surgeons that they should consider this question, and ascertain whether the numerous cases of appendicitis, &c., now presenting themselves are either immediately or remotely dependent on influenza, and should there be a consensus of opinion that such is the case, then surely influenza should be considered on a par with other infectious diseases, scarlet fever, &c. It should be notifiable, and precaution against its conveyance to others should be compulsory. I look upon influenza as a very terrible disease, the cause of a vast number of deaths altogether apart from the question of whether or not it is the cause of the "appendicitis epidemic." And yet what do we find? Business men in the City telling their clients plainly that they are so ill with the "flue" that they could scarcely come to business, quite careless of the fact that they are at the moment transferring their sufferings—even to death—to their unsuspecting clients. Even some medical men, who are aware of the fact that they have influenza, continue their work as long as their temperature will allow them.

These hotbeds of disease and death do not hesitate, in their ignorance, to use public conveyances; do not hesitate to mix with others or even to go to places of amusement. If it concerned themselves alone, perhaps no one could interfere, but as each case, though itself apparently insignificant, may quite possibly become the cause of death to others, I think it becomes the duty of public health officers to see that in future, so far as law is concerned, influenza shall be put on a par with scarlet fever.

I am, Sir, yours truly,
A. T. NORTON.

Ashampstead.

CAUSES OF APPENDICITIS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Mr. W. V. Black ends his interesting letter with the statement that "appendicitis is a modern affection," but does not give the evidence on which he bases this opinion. If he would kindly do so it would be very valuable. I am old enough to recollect the days before Lister, the days when the idea of operating for appendicitis was practically never entertained. All that could be done was to attempt to palliate the pain. The patients recovered or died as a rule in spite of treatment, perhaps not rarely because of it. In private practice *post-mortem* examinations to verify the exact nature of the malady were never made; the deaths were invariably certified as due to enteritis, or peritonitis, or such-like causes. With regard to hospital practice, I cannot speak so confidently. It would be valuable if the records of some of our great hospitals where the causes of death were most systematically sought for could be examined with a view to elucidating the question Mr. Black's letter suggests.

I am, Sir, your truly,

SENEX.

February 9th, 1905.

PROFESSIONAL ETIQUETTE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—At the top of the second column, page 144, of this week's MEDICAL PRESS AND CIRCULAR (Feb. 8), I read the following words:—"It is needless to say what opinion medical men are likely to hold with regard to a *confre* who attends a patient without the *knowledge and consent* of the patient's own medical man, and almost needless to say that an ordinary Court cannot be made to see the matter in the same light." I have italicised the words "knowledge and consent" for I think that if a patient wishes to have the opinion of another doctor upon his case it is one thing, but that if he must not do so without the "consent" of his own doctor it is another.

If a jury would take one view, and the profession a very different one on such a matter as this, it would be well if the profession and the public came to some understanding upon it.

It seems to me that the liberty of the individual,

and the good of the patient, ought to come before the doctor and his interests in the practice of our profession. The public will lose confidence in and respect for doctors if this great principle is not observed and practised.

I am, Sir, yours truly,

R. L.

Obituary.

DR. ALLEN FENNINGS.

WE regret to announce the death of Dr Allen Fenning at St. Leonards from double pneumonia, after four day's illness, at the age of sixty years. He had resided at St. Leonards for twelve years, and had previously practised for thirty years at Notting Hill. He was formerly house surgeon at Charing Cross Hospital, where he received his medical education. In 1864 he took the diploma of the English College of Surgeons, and in 1866 that of the Edinburgh College, and the degree M.D. of St. Andrews in 1885.

FREDERICK ROBINSON, L.R.C.P., L.R.C.S.I., OF BLACKBURN.

THE death is announced of Dr. Frederick Robinson, the police surgeon of Blackburn, on the 9th inst., after a very brief illness. A native of County Wexford, his father, a Yorkshireman, was lieutenant on board the "Investigator" when that vessel sailed to the Arctic regions in search of Sir John Franklin. Dr. Robinson, who was fifty-seven years of age, had practised in Blackburn nearly twenty-five years, and was appointed police surgeon about three years ago. His loss will be mourned by a large circle of acquaintances and friends.

SURGEON-GENERAL THOMAS WALSH.

WE regret to have to record the death of Surgeon-General Walsh, late of the Army Medical Service, which occurred during the past week at his residence near Dublin. Surgeon-General Walsh joined the Army as an assistant surgeon in 1858. He became surgeon-major in 1875, and brigade-surgeon in 1884. He had considerable experience of active service, as he served in the Afridi Expedition of 1877-78, in the Afghan War of 1879-80, and in the Egyptian War of 1882. In the last campaign he was present at the battles of Tel-el-Mahuta, Kassassin, and Tel-el-Kebir. Surgeon-General Walsh retired in 1898, after forty years' service.

HARRY HARLOCK, L.R.C.P.LOND., M.R.C.S.

THE death is announced of Mr. Harry Harlock, L.R.C.P., M.R.C.S. Eng., who resided for some years near Chichester. He was recovering from an attack of influenza when he contracted pneumonia, to which he succumbed on Monday at the age of 47. The deceased doctor was local medical officer of health and vaccination officer, and an hon. surgeon of Chichester Infirmary. Formerly he resided at Singleton, and prior to coming to Sussex was house-surgeon at Brecon Co. Infirmary, and hon. assistant surgeon at H.M. county and borough prison, Brecknock. The greatest sympathy is felt in the neighbourhood for Mrs. Harlock, who, with her husband, enjoyed the friendship and esteem of a large number of people in the western part of Sussex.

LUTHER HOLDEN, F.R.C.S.

It is with great regret we announce the death of Mr. Luther Holden, at Putney, on February 6th, at the advanced age of 90. He became a member of the College in 1838, and gave instruction to students non-officially in the dissecting room for several years, and soon gained a high reputation as a teacher. Holden was destined to be the last survivor of the candidates who passed the first examination ever held for the diploma of Fellow of the College of Surgeons. In 1846 he became Demonstrator of Anatomy in the Medical School of St. Bartholomew's Hospital, and entered his name as such in the *Medical Directory*. In

1859 he was elected lecturer on descriptive and surgical anatomy conjointly with Skey, but resigned in 1871. His greatest contribution to contemporary medicine was "Human Osteology," remarkable for its beautiful drawings and the then new system of marking muscles attachments. "Medical and Surgical Landmarks," the result of lecture and dissecting-room demonstration, is equally well known. He was a clever and scientific surgeon, though in the beginning having no antiseptic means at his disposal. He was elected a member of Council (F.R.C.S.) in 1863, and served two full terms on that Board, retiring in 1884, and from 1873 to 1883 was a member of the Court of Examiners. In 1881 he delivered the Hunterian Oration. Holden was President of the College in 1879, having held the position of Vice-President during the two immediately previous years. Of splendid physique and excelling in country sports, he was also fond of travelling, and at the advanced age of 83 went to Johannesburg, where he received a warm welcome from the profession. He had no children, but his second wife, well known as a philanthropist, survives him.

CHARLES BATTEN GRACIE, M.R.C.S.ENG.,
L.R.C.P.ED.

THE death took place on the 4th inst., after a brief illness, of Dr. C. Batten Gracie, for over twenty years one of the medical practitioners of Burntisland. Dr. Gracie was a native of Birkenhead, and was in his 49th year, his death being due to heart failure. He was medically educated at Liverpool and at University College, London, whence he took the M.R.C.S.Eng. in 1882, and the L.R.C.P.ED. in the same year. Dr. Gracie was a director of the local golf company at the time the course was extended. He enjoyed the game, and as recently as Wednesday last visited the Golf House Club, when a feeling of faintness proved to be a premonition of the fatal issue.

JOHN STEWART MATHEWS, M.B., C.M.EDIN.,
OF BURNHAM.

WE regret to hear that, on the 5th inst., Dr. John Stewart Mathews, a well-known practitioner of Burnham, was found dead in bed in his residence. The deceased gentleman had recently been treated for an affection of the heart. Dr. Mathews, who graduated in Edinburgh University so long ago as 1868, studied at London, Paris, and Edinburgh.

CHARLES PEGGE, M.R.C.S., L.R.C.P.LOND.

WE regret to note the death of Dr. Charles Pegge on the 3rd inst., at his residence, Briton Ferry. The deceased gentleman, who was about 73 years of age, came to the district a young man in the year 1857. He was a director of the Briton Ferry Works, and for many years chairman and director of the Melyn Timplat Works. He was parish doctor of Briton Ferry, and the medical officer of the local board. His medical education was conducted in Guy's Hospital, London, and he took the M.R.C.S. and L.R.C.P.London qualifications in 1856.

ROBSON ROOSE, M.D.BRUX., F.R.C.P.ED.,
M.R.C.S.ENG.

WE regret to announce the death of Dr. Robson Roose, of Hill Street, London, on the 12th inst., in his 57th year. Dr. Roose entered the medical profession in 1870 as licentiate of the Apothecaries of London, and soon afterwards obtained the licences of the Royal Colleges of Physicians and of Surgeons of Edinburgh. In 1872 he became a member of the Royal College of Surgeons of England, and in 1875 a member of the Royal College of Physicians of Edinburgh, of which he was elected a Fellow in 1877, obtaining in the same year the Doctorate of Medicine of the University of Brussels. He practised for some years at Brighton, afterwards in Hill Street, where he soon obtained a large and fashionable practice.

Literature.

CRITCHLEY'S SANITARY LAW. (a)

THE student of sanitary law has hitherto been compelled to consult various large and bulky volumes in order to obtain the facts about which he wishes to make certain. It is to obviate this difficulty that the present handbook has been prepared. It presents the whole subject in a nutshell. All the important Acts bearing upon a medical officer of health's duties have been carefully summarised, and rendered clearer by the omission of unnecessary legal phraseology. In addition, the present state of the law relating to disinfection, slaughter-houses, and the like is presented in brief. A series of questions taken from various examination papers is appended. We certainly consider that the author has conferred a service in preparing these "aids." Though unpretentious, this small book will be found invaluable as a guide to medical officers of health and others interested in matters relating to public health.

DIAGNOSTIC BACTERIOLOGY. (b)

THIS well-designed and excellently executed manual may well be recommended to busy practitioners desirous of applying the benefits of the best bacteriological researches to the daily needs of clinical work. The title is comprehensive and ambitious, but the author has admirably fulfilled the task he has set himself, and has supplied a really practical work which will prove a trustworthy guide to the clinician. Bacteriological examination of morbid products is nowadays essential to complete diagnosis in many diseases. The practitioner who has not enjoyed the opportunities of studying in a laboratory the progress of modern methods is oftentimes perplexed and confused by the intricacies and complexities of descriptions as given in many works on bacteriology. Dr. Coles knows the needs and understands the difficulties of the practitioner, and has succeeded in meeting the wants of the hard worked but conscientious clinician. The book contains plain, straightforward, and thoroughly trustworthy directions for the spreading, fixing, and staining of films. An important section of the volume is taken up with a valuable study of the acid-fast bacteria and useful deductions for the differentiation of the pseudo-tubercle bacilli are clearly given. The section devoted to a study of the morphological characters of the tubercle and pseudo-tubercle bacilli, and the determination of the degree of their resistance to acids and other agents contains the records of much valuable painstaking research.

The work also contains concise, but sufficiently complete descriptions of the best methods for investigating the organisms met with in gonorrhœa, pneumonia, influenza, diphtheria, plague, actinomycosis, anthrax, relapsing fever, parasitic affections of the skin and hair and other diseases.

There are also useful sections on serum diagnosis and the attractive question of cyto-diagnosis receives attention.

Dr. Coles writes in a thoroughly scientific spirit. He takes a wide and judicious outlook, and has carefully studied the work of reliable investigators. But the work throughout indicates that the writer is no mere compiler but an original thinker, and a thoroughly practical worker. In every portion of the volume there is a personal ring of individual experience which not only attracts but stamps the work as that of a trustworthy and conscientious and scientifically-minded investigator. We commend the work to all practitioners desirous of keeping abreast of bacteriology in its practical applications to the diagnosis of disease.

(b) "Clinical Diagnostic Bacteriology, including Serum Diagnosis and Cytodiagnosis." By Alfred C. Coles, M.D., D.Sc., F.R.S.E. Pp. 297, with Coloured Plates. London: J. and A. Churchill. 1904.

Medical News.

Cairo School of Medicine.

DR. SYMMERS, who is leaving the service of the Egyptian Government to take up a professorship at Belfast was entertained at dinner by the Cairo School of Medicine. There were present Dr. Ibrahim Hassan Pasha, Dr. H. P. Keatinge, Dr. H. Bitter, Dr. G. Elliot-Smith, Dr. W. H. Wilson, Dr. J. R. Naylor, Dr. A. Looss, Dr. W. A. Schmidt, Dr. F. Milton, Dr. Tribe, Judge Halton, Dr. Fisher, Dr. Beddoe, Dr. Phillips, Dr. Madden, Dr. Nolan, Dr. Shukry Bey, Dr. Innes Bey, Dr. Arloing, Dr. Sandwith, Dr. Symmers, Dr. Harrison, and Dr. Todd. Dr. Symmers was afterwards presented with a fine silver bowl from past and present students.

Anthrax in West Sussex.

A BULLOCK which died on the farm of Mr. John Helyer, of Littlehampton, has been certified to have been affected with anthrax, and has been destroyed by burning. This is the third case of anthrax in the district within the past three weeks, the previous cases occurring at Walberton and Angmering.

Mr. Vanderbilt's Gratitude.

WHEN in Paris recently Mr. and Mrs. W. K. Vanderbilt, the well-known millionaire, both suffered from rheumatism, and were completely cured by Professor Gauthier's light-ray baths. Grateful for his cure, the millionaire sent a cheque for ten times the amount charged, and enclosed a second cheque for £40,000 to complete a dispensary where the poor could have the same treatment free. This hot air cure, Englishmen may be reminded, was invented on this side of the Channel. The original pattern was that of the late Mr. L. A. Tallerman.

International Society of Tuberculosis.

A NEW scientific society has recently been founded in Paris, under the name of Société Internationale de la Tuberculose. Its office is in Paris, where meetings are held monthly, on notice from the general secretary. The scope of this Association is the study of all questions concerning tuberculosis and the centralisation of means of defence. Its work will be regularly published. The association is composed of medical men or scientists holding diplomas from French or foreign universities and colleges. Admission may be obtained by application to the President, which application must be accepted by a committee elected at a general meeting. The annual subscription is 10 francs (os.) For further particulars and for applications address M. le Docteur Georges Petit, General Secretary, 51, Rue du Rocher, Paris, France.

Royal College of Surgeons of England.

THE following candidates, having passed the required examinations and conformed to the by-laws, have been admitted members of the College:—Harry Andreae, Charles Ernest Augustus Armitage, William Arnott, Harold Ramsey Popham Baker, William Girling Ball, Sydney Barradell-Smith, Samuel Landor Benton, Gerald Francis Bird, Arthur Herbert Bond, Robert Henry Bott, Stanley Bott, John Bourdas, William Quinton Bown, Robert Daniel Bridger, Frederick William Broderick, Arthur Williamson Brodribb, Walter Donald Carruthers, William Rex Collingridge, Wilbye Cooper, Robert Hugh Cotton, Harold George Shackelford Courtney, Arthur Douglas Crofts, Leonard Daft, Harold Stewart Dickson, John Harmer Drew, Charles Edward Droop, Lawrence Dukes, Bertram Joseph Eccles, Harry Farncombe, Wilfrid Fawcett, George Edward Ferguson, Charles Henry Fielding, Henry Edward Fox, Francis Gayner, Joseph Sutherland Aikin Graham, Alfred Wallace Harvey, Christopher Patey Harvey, Albert Ernest Henton, James Edward Hoar, Cecil Dacre More Holbrooke, Walter Goldie Howarth, Norman Haliburton Hume, James Aubrey Ireland, Archie Vivian Jubb, Colin King, Frederick Spencer Lister, John

Daniel Stuart Lloyd, Otto William Axel Lowe, Ernest McIntyre, Harold Charles Mamlock, Alexander Manuel, Herbert Frank Marshall, Aurelius Victor Maybury, Charles William Moore, Conwy Llewellyn Morgan, Arnold Morris, Jonas Morris, Leonard Newsom Morris Joseph Archie Mulvany, Alexander Murdock, Edgar Coningsby Myatt, William Steward Nealor, William Henry Newton, Jeffrey Alexander Amherst Orlebar, William Erasmus Paramore, Herbert Wilberforce Perkins, Bernard Pickering, Stephen Hugh Pitcairn, John Edward Pratt, Reginald Puttock, Frank Douglas Roberts, George William Ross, Leslie Martin Rosten, Francis John Russell, William Mackenzie Sadler, Julius Benedict Simpson, Eric MacLeod Smith, Evelyn Charles Sprawson, Ambrose Thomas Stanton, Harold Foster Strickland, James Herbert Sutcliffe, Leonard Smith Talbot, Gordon Wilson Thomas, Isaac Thompson, James Aubrey Torrens, Sydney Booth Turner, William George Turner, Frederick Graham Twigg, Fred Newton Walsh, Albert James Walton, Horace Walshman Ward, Stanley Herbert Warren, Stanley Martin Wells, George Trench Western, Samuel Henry Westman, Francis Henry Whitehead, Alfred James Wigmore, Eric Maurice Wilkins, Percy Charles Woollett.

Royal College of Physicians of Edinburgh, Royal College of Surgeons of Edinburgh, and Faculty of Physicians and Surgeons of Glasgow.

THE quarterly examinations of the above Board, held in Edinburgh, were concluded on the 28th ult., with the following results:—

Final Examination.—Of 75 candidates entered the following 34 passed the examination and were admitted L.R.C.P.E., L.R.C.S.E., and L.F.P. and S.G.:—Alexander Robb MacIntyre MacIlraith, Joseph Millar Gordon Ewing, William MacLaren MacIlraith, John Roberts, Arthur Gilbert Michelsen Middleton, John George McLeod, Alfred Lionel Johnston, James Archer Brown, Isaac David, John Hay Heddle, Frederick Nassau Hughes, Peter John Fisher Houston, Mary Brice Carr, George Christopher Grundy, Martin Arnold Gibbs, George Abeyesinhe, Anna Mary Mulholland, Sorab Kaikhoshru Engineer, Nuno Joseph Rodrigues, John Joseph Lawton, David Smith, Nicholas David Sweetnam, James Samuel Nelson, John Lawrence Power, Albert Davies Edwards, John Forbes Webster, Robert Whitson Telford, Edward Tambyah MacIntyre, Ernest Howard Edward Coghlan, Francis Baillie, Dhanjibhai Fardunji Mullan-Feroze, William Frank Hague Ives, Edgar Arthur King, and Waradana Aralis de Silva, and 5 passed in Medicine and therapeutics, 2 in surgery and surgical anatomy, 5 in midwifery, and 5 in Medical Jurisprudence.

Royal Army Medical Corps.

THE undermentioned gentlemen were successful at the recent examination in London for Commissions in the Royal Army Medical Corps (68 candidates):—Charles Pinkerton Thomson, M.D.Glas., George Wykeham Heron, M.R.C.S.Eng., L.R.C.P., Robert John Bertram Buchanan, L.R.C.P. and S.I., George Brooke Forbes Churchill, M.R.C.S.Eng., L.R.C.P., William Steward Nealor, M.R.C.S.Eng., L.R.C.P., James Edward Hoar, M.R.C.S.Eng., L.R.C.P., Richard Graves Meredith, L.A.H.Dub., M.B. R.U.I., Frederick Emilius Roberts, M.R.C.S.Eng., L.R.C.P., George Smith Wallace, M.B., Glas., Wilfred Parsons, M.R.C.S.Eng., L.R.C.P., Arthur Anderson McNeight, M.B.Dub., Ernest Brabazon Booth, M.D.Dub., Thomas Holroyd Gibbon, M.D.Dub., Richard James Campbell Thompson, M.R.C.S.Eng., L.R.C.P., Ernest George Robert Lithgow, M.R.C.S.Eng., L.R.C.P., Pierce Power, M.B., R.U.I., Charles William O'Brien, M.R.C.S.Eng., L.R.C.P., Ryder Percival Nash, L.R.C.P. and S.Edin., James Sydney Pascoe, M.R.C.S.Eng., L.R.C.P., Cecil Dacre More Holbrooke, M.R.C.S.Eng., L.R.C.P., John Maurice Bisdie Rahilly, M.B., B.S., George Grant Tabuteau, L.R.C.P. and S.I., Richard Edmond Humphrey, L.R.C.P. and S.I., William George Maydon, M.B.Aber., Garfield Ormrod, M.B. Edin.

Notices to Correspondents, Short Letters, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initial*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in re-forwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

ORIGINAL ARTICLES or **LETTERS** intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

G. H. B.—Things as you say have not changed for the betterment of the profession, but we are afraid its members have themselves to thank in great measure for the trend of events. We never had a doubt as to the ultimate result if the measure became law, and worked long and hard to stir up the profession with regard to it, but the usual apathy prevailed and before the present year has run its course, a still more serious state of things will, we fear, be experienced.

A VACANCY.

AN American Christian Scientist lately had under her care a lady who was taking a course of "absent" treatment. The course was interrupted by the patient absenting herself from this terrestrial globe—a fact not communicated to the "healer." The bill for fees came in in good course, when the husband to his surprise found he had been charged for two weeks after his wife's death. His indignant protest was calmly met by the fair scientist with the response, "Oh! I thought I noticed a vacancy about that time."

DR. MOSS will find the treatment pursued in the Paris Hospitals in a similar case in our issue for January 18th, under the heading of "Paris Clinical Lectures."

INSURANCE.—A company has a right of terminating a policy whenever they please, nor are they under any obligations to justify their action.

J. D. R.—The series you refer to is "English Men of Science," and edited by Dr. T. Reynolds Green.

DR. W.—Echinococcus infection is such an infinitesimal risk, that preventive measures possess at most a technical scientific interest or value.

ABSTAIN.—You would find all you want in Dr. Valpy French's "Nineteen Centuries of Drink in England."

MR. H. WILSON.—We fear the advice given in the publication referred to is not always disinterested. Itinerant Guides are necessarily biased, and the most reliable information is the experience of friends who have actually resided there. From personal knowledge we should certainly not recommend Biarritz as a winter resort for any but the most energetic. In the early spring on the other hand, the climatic conditions are most delightful. Algiers, the Riviera, or Egypt, would be much more suitable for the case you speak of.

LEX.—Under Sec. 21 of the Coroner's Act 1887, the coroner is empowered to summon the medical man, if any, who attended the deceased in his last illness and "may direct such medical witness to make a post-mortem examination."

J. L. S.—Some cases of carnophobia have been known, one in which a young soldier showed an absolute repugnance to meat and complained of general urticaria and weakness after partaking of that kind of food.

UNREGISTERED.—The mistake arose because you confounded the *Medical Register* with the *Medical Directory*. Anyone who is doubtful whether his address is in the former or incorrect should write at once to the office. A post-card is always sent in answer.

D. P. H.—An occupation rash is to be suspected when it begins on the hands and forearms. In such cases no routine diagnosis of eczema should be accepted as satisfactory.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, FEBRUARY 15th.

ROYAL MICROSCOPICAL SOCIETY (20 HANOVER SQUARE, W.)—8 p.m. Paper:—Mr. J. E. Stead: Practical Micro-Metallography with Experimental Demonstration.

ROYAL METEOROLOGICAL SOCIETY (70 VICTORIA STREET, WESTMINSTER, S.W.)—7.30 p.m. Papers:—Mr. E. Mawley: Report on the Phenological Observations for 1904.—Dr. H. Elias and Mr. J. H. Field: Observations made during a Balloon Ascent at Berlin, Sept. 1st, 1904.—Mr. J. R. Sutton: The Winds of East London, Cape Colony.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 CHANCERY STREET, W.C.)—4 p.m. Mr. E. Owen: Clinique. (Surgical.) 5.15 p.m. Dr. G. H. Savage: The After-Effects of an Attack of Mental Disease. **CENTRAL LONDON THROAT AND EAR HOSPITAL** (Gray's Inn Road, W.C.)—5 p.m. Demonstration.—Dr. D. Grant: Larynx.

THURSDAY, FEBRUARY 16th.

CHILDHOOD SOCIETY AND THE BRITISH CHILD-STUDY ASSOCIATION (Parkes Museum, Margaret Street, W.)—8 p.m. Discussion on the

Proposed Anthropometric Survey (opened by Mr. E. W. Braubrook, Dr. J. Gray, Prof. H. B. Kenwood, and Dr. F. Warner). (Arranged by the Childhood Society.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 CHANCERY STREET, W.C.)—4 p.m. Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m. Mr. E. Clarke: Ocular Headache: Its Causes, Diagnosis, and Treatment.

MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (7 Fitzroy Square, W.)—5 p.m. Lecture: Dr. G. Johnston: Demonstration of Selected Cases. (Post Graduate Course.)

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.)—4.30 p.m. Dr. A. J. Whiting: Electro-Diagnosis.

FRIDAY, FEBRUARY 17th.

EPIDEMIOLOGICAL SOCIETY OF LONDON (11 Chandos Street, Cavendish Square, W.)—8.30 p.m. Paper: Prof. E. J. McWeeney: The Pre-tosa in Relation to Disease (illustrated by specimens and slides).

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 CHANCERY STREET, W.C.)—4 p.m. Mr. A. Lawson: Clinique. (Eye.)

TUESDAY, FEBRUARY 21st.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.)—4.30 p.m. Dr. G. N. Meachen: Seborrhoea and Seborrhoeic Dermatitis.

Vacancies.

Royal London Ophthalmic Hospital (Moorfields Eye Hospital), City Road, E.C.—Curator and Librarian. Salary £120 a year. Applications to Robert J. Bland, Secretary.

St. Helens.—Surgeon to the Works Sick Club. Salary £200 per annum, with furnished residence, light, heating, and attendance, sine board. Applications to F. B., Box 36, Post Office, St. Helens.

Brompton Hospital for Consumption and Diseases of the Chest.—Assistant Resident Medical Officer. Salary £100 per annum, with board and residence. Applications to the Secretary.

Egyptian Government—Ministry of Public Instruction.—Professor of Pathology and Bacteriology at the School of Medicine, Cairo. Salary £200 per annum. Applications to the Director, Government School of Medicine, Cairo, Egypt.

Eastern Counties' Asylum for Idiots, Imbeciles, and the Feeble-Minded, Colchester.—Resident Medical Attendant. Salary £25 per annum, with furnished apartments in the Asylum, board, and washing. Applications to John J. C. Turner, Secretary.

Corporation of Manchester.—Monsal Fever Hospital.—Fourth Medical Assistant. Salary £100 per annum, with board, lodging and washing. Applications to the Chairman of the Sanitary Committee, Public Health Office, Town Hall, Manchester.

Birkenhead and Wirral Children's Hospital, Woodchurch Road, Birkenhead.—Male House Surgeon. Salary £100 per annum, with board, residence, and laundry. Applications to F. W. Archer, 5 Storeton Road, Birkenhead.

Hartlepool Hospital.—House Surgeon. Salary £100 per annum, with board, washing, and lodging in the institution. Applications to Robert M. Edgar, Assistant Secretary, 5, Catherine Street, Hartlepool.

Royal Buckinghamshire Hospital, Aylesbury.—House Surgeon. Salary £100 per annum, with board, and furnished apartments. Applications to Geo. Fell, Secretary, Rickford's Hill, Aylesbury.

Bethnal Green Infirmary.—Assistant Medical Officer. Salary £100 per annum. Applications to the Medical Superintendent of the Infirmary, Cambridge Road, N.E.

Appointments.

BURNETT, ARTHUR H., M.R.C.S. Eng., L.R.C.P. Lond., House Surgeon to the Rochdale Infirmary.

CROSLAND, G. W. KILNER, M.R.C.S., L.R.C.P. Lond., Honorary Surgeon to the Huddersfield Infirmary.

PEARSON, J. SIDNEY, M.A. Cantab., M.R.C.S., L.R.C.P. Lond., Officer and House Surgeon to the Victoria Hospital for Children, Chelsea.

ROWELL, J. GEORGE, M.R.C.S., L.R.C.P. Lond., Honorary Surgeon to the Huddersfield Infirmary.

SCOTT, GRAHAM, M.R.C.S., L.R.C.P. Lond., Junior Anaesthetist to the Central London Throat and Ear Hospital.

Births.

SASS.—On February 12th, at 75 Holland Park Avenue, W., the wife of Wilfred Sass, M.R.C.S., L.R.C.P. Lond., of a son.

TRAILL-THOMPSON.—On February 7th, at Claverack, Wembley, Middlesex, the wife of Dr. W. D. Traill-Thompson, of a daughter.

Marriages.

PATERSON—HOLMAN.—On February 11th, at the Parish Church, Budleigh Salterton, John Yates Paterson, of Finchley, Middlesex, and 8, Breams Buildings, Chancery Lane, London, to Bessie Penelope Camplin Holman, eldest daughter of the late Charles Henry Holman, M.R.C.S., of Niton, Isle of Wight.

Deaths.

FENNINGS.—On February 9th, at 1 Pevensey Road, St. Leonards-on-Sea, Allen Fennings, M.D., M.R.C.S., L.R.C.P., I.S.A.

BOOSE.—On February 12th, F. C. Robson Boose, M.D., LL.D., F.R.C.P. Edin., of Hill Street, Berkeley Square, in his 57th year.

EVLIN, BERESFORD.—On February 13th, after a long and painful illness, Sarah Louisa, the dearly-beloved wife of Beresford Evlyn, M.D., Wimpole Street.

PLAISTER.—On February 11th, at Pembury House, Tottenham, Alice Emma, the dearly-beloved wife of W. H. Plaister, M.R.C.S., aged 55.

Inaugural Address ON THE

RISE AND PROGRESS OF GYNÆCOLOGY. (a)

By WILLIAM ALEXANDER, M.D., F.R.C.S.,
Honorary Surgeon, Royal Southern Hospital, Liverpool;
President of the British Gynæcological Society.

I PROPOSE to bring before you to-night my own experience of the rise and progress of gynæcology. When I was a student of medicine, there was no gynæcology worthy of the name. It is true that McDowell had performed several ovariectomies early in the century, and that Wells, Keith, and others, at the time of which I am speaking, were engaged in placing abdominal operations upon a sound foundation. Even the foremost of the profession in the cities and towns of Britain outside the capitals only opened the abdomen occasionally, and with discouraging results.

During my pupilage, we had medicine, surgery and midwifery. The abdomen belonged to the physician, and "inflammation" was a name of dread, and included many diseases now treated successfully by the surgeon or gynæcologist. Abdominal tumours were, in my early hospital days, referred in the first instance to the physician, and it was only on the failure of medical means, which sometimes included tapping, that the case was handed over to the operator. The delays caused in this way were often detrimental to the prospects of the case, and it required a severe contest to obtain an alteration of the rule, so that abdominal tumours might be sent direct to the surgeon or gynæcologist.

Whilst the physician treated all the internal diseases of the abdomen, the obstetrician did the necessary repairs after parturition, such as perineorrhaphy, the woman naturally consulting the obstetrician who attended her during her confinement for any trouble with the reproductive organs.

The obstetricians, with their small experience in operative work, were very often indifferent surgeons, and in their uncertain command of time did not always care to have the anxiety and worry that accompany the arrangements for, and the trouble connected with, an operation.

In my young days there were general surgeons who practised the few operations on women then common, but most of their time was devoted to general surgery. To these, the obstetricians handed over their cases, and these were the representatives of the gynæcologists of the present day, but with too much of the surgical art in their composition and too little of the other arts that make up true gynæcologists.

When gynæcology embarked upon an independent course, she started with certain gifts as "send-offs" from her three elder sisters. Medicine gave her the knowledge that the reproductive organs were part and

parcel of the whole economy. These organs when diseased mutually acted and reacted upon all the other organs, and this relation requires to be kept in view by the gynæcologist, if he would avoid the commission of serious errors.

From the obstetrician, gynæcology obtained a knowledge of the changes produced by pregnancy on the reproductive organs and of the damage that parturition causes or leaves in its train. The obstetrician and the gynæcologist work in the same field, and such near relatives should naturally be also firm friends.

To surgery, however, gynæcology is most indebted. The great successes of the past half-century have been on the surgical side of gynæcology. It may be said that gynæcology and surgery have flourished side by side, one branch now teaching, and now being taught by, the other, and both assisting in the great advance that has taken place in all surgical procedures. Surgery and gynæcology have domains that are adjacent or that sometimes overlap, and work on the boundary requires a knowledge of both specialties. For example, a diseased ovary may be complicated with an adherent appendix, and the latter has to be removed by a surgical operation. The bladder or intestines may be injured in operation on the uterus, and the repair must be done by the operator. Both work in the abdomen, and both require to have a common knowledge of how to work safely there.

This common knowledge is of such great value that some men who possess it in a high degree take up the rôle of abdominal surgeons. Some of your former Presidents were as much at home in operating on the gall-bladder as on the uterus; on an appendix vermiformis as upon the uterine appendages. Many of the Fellows are not pure gynæcological specialists, but are able to deal with any surgical complication they may meet with in their usual work. This is a good feature, and gives broader views, improves the practice, and allows men to attach themselves to gynæcology whose minds are enriched with experience in cognate studies. This is different from the narrow groove in which candidates for other specialties have to travel. Their field is much restricted, and whilst waiting for practice, the candidate must not even look over the hedge into neighbouring fields, and should he allow it to be known that he knows anything about other medical or surgical subjects, the purity of his specialism will be dimmed and his prospects impaired. This method of natural selection of specialists in gynæcology, whilst allowing more freedom, brings to their society men of wider and of larger experience. The nature of the work requires such men, as the conditions to be met with on opening the abdomen may be so complicated and varied that although the primary operation is gynæcological, the complications may require the highest surgical experience.

In my early days the representatives of the present class of gynæcologists were very different men to what they are now. They were not surgeons, but were experts in applying pessaries and fixing the womb by such supports to the exact position that they considered normal. Erosions of the cervix, endometritis,

(a) Read at a meeting of the British Gynæcological Society on February 9th, 1905.

and polypi uteri were their staple diseases. Many of these men were leaders of their age, but the sole monuments we possess of many now are pessaries which are known by their several names. Now, although we do not consider the harmless art of pessary inventing to be a crime, it would be difficult at the present day to build a reputation upon it. While we may not do so much harm by the universal application of pessaries as our forefathers may have done, we certainly cannot use them with the same skill, and we should take care that a knowledge of their use does not die out in the younger generations. The removal of uterine polypi was a favourite operation, and remembering as I do the numerous operations of the kind then performed, I wonder what blight has destroyed the crop of these tumours. In fact, after I commenced practice, it was quite unusual for a gynaecological case to consult me who, according to her statement, had not had a polypus removed at some previous time. Touching up erosions and passing medicaments into the uterus for endometritis were common events. The passage of a uterine sound was a routine proceeding, and no doubt often produced inconvenient or even deplorable results. The use of the sound and the speculum were then novelties, and no examination was held to be complete where both instruments were not used. Now the *tactus eruditus* takes the place of both, and the instruments are used rarely and only for specific purposes.

One of the most serious operations of that time was repair of the perineum, and I remember one case which shows the contrast between the practice then and now in perineorrhaphy. The surgeon took some time to take thin parings off the edges of the cleft, which bled profusely, and ice-cold water on compresses was applied to check the bleeding. Silk or silver wire sutures were used, and several attempts were generally necessary to secure a fair result. The operation lasted three hours, the patient being, of course, much blanched at the end. In a report of that time which I remember, two out of twelve cases died after operation, and only one of the twelve was found to be successful twelve months afterwards. Now, thanks to the advances made by Tait and others, the repair of a perineum does not take many more minutes than it then took hours, and a death from the operation is a most exceptional event. I have not heard of any for many years. The operations are now generally a success from a surgical point of view at the first attempt, and the object of the operation is more often attained for a much longer period of time. Abdominal operations were not much performed, and when they were they were mostly fatal. Spencer Wells had at that time commenced to compile his thousand cases of ovariectomy, with a gradually decreasing mortality, reaching, in 1869, 145 cases with a mortality of 37, or 25.6 per cent.

If I describe a picture of my student days, we will be able to see at a glance why abdominal surgery was not a success then. Take a scene which is vividly impressed upon my mind and occurred in 1868. The operating surgeon comes into the theatre faultlessly dressed, linen irremovable, and nails without the slightest trace of mourning, a spotless, well-groomed gentleman. He takes off his coat, rolls up his sleeves, retires to a passage that runs behind the theatre, whence he emerges attired in an old dusty coat, bespattered with the blood or pus of a long series of former operations. He pulls the collar up about his ears and the flaps of the breast of the coat across his chest. The sleeves are folded at the wrists. He then picks up the silk intended for the ligatures and a piece of cobbler's wax, and while he is waxing the threads he gives a clinical lecture on the case about to be operated on. When each silk thread is waxed sufficiently, he hangs it over the ledge of the theatre, where it remains until ready for use. The assistants wear old coats or jackets or their ordinary clothes, their hands are washed if dirty, not specially as a matter of routine. The instruments are taken out of baize-lined cases as they are wanted, and appear to us to be bril-

liantly clean. The operation table, a wooden structure with movable parts, sits in a narrow area surrounded by the theatre seats, where 100 students, many of them fresh from the dissecting-room, are craning over, and their effluvia pervades the atmosphere over the wound. But worse remains. The operation-table sits on a trap-door in the floor. An opening in the floor is closed, but is not hermetically sealed, by the trap-door. This opening leads to the mortuary beneath, and is it any wonder that a few days after operation we oftentimes saw the dead body of a previous operation case hauled up and the disease from which he died demonstrated to us by the same surgeon who had performed the operation? In tones of deep sorrow he would describe the sad history of the case, and the inexplicable blood poisoning that had marred what for a day or so promised to be such a brilliant success. We wonder how any operation cases survived under such circumstances, but many did, and about one in four or five was the usual death-rate in amputations at that time. I remember an amputation of the thigh healing by first intention. The surgery was excellent, and some operators had instinctive ideas of surgical cleanliness, and obtained successes without being able to give a reason, much less to teach the elements of their successes to others. They were supposed to be "lucky beggars," and were much envied by their fellows. They had no guide to point out the right ways and the wrong until Lister came and enunciated the germ theory of disease. This was Lister's great discovery. The use of carbolic acid as a dressing was a detail, and only the first method of applying the principles of the germ theory to treatment. The diffusion of such a germicide as carbolic acid into the atmosphere of operation-rooms, such as I have described, and over the hands of the surgeons and over the skin of the patients, worked wonders upon the results of general surgery. Old coats disappeared, *post-mortem* rooms were banished to the outside, surgeons ceased to be pathologists, and dissecting students were dealt with so that they ceased to be a menace to operators. In abdominal surgery the results were no less striking with many operators. The uniform fatalities of many places were now varied by successes, although the spray and the use of strong lotions did harm when applied to the peritoneum too profusely.

In 1877, when Lister came to London, Sir Spencer Wells had his mortality reduced from 25.5 to 9 per cent. Wells was a born ovariologist. He had no more enlightenment than his contemporaries upon the real causes of blood poisoning, and knew nothing of the germ theory or of antiseptics till he had placed ovariectomy on a sound basis; but he had unconscious instincts that led him to choose the right way through the fogs in which he had to live and work. Listen to the following quotation from Sir Spencer Wells' book, entitled "Ovarian and Uterine Tumours," 1882:—

At page 218, he writes:—"Long before Lister had tried any of his methods, I had insisted upon all possible care in protecting patients before, during, and after operation, from all known causes of excessive mortality, and I took unusual precautions against any risk of contagious or infective disease being communicated from without, or the development from within of anything that could set up traumatic fever or blood poisoning. I contended that obstetrics and operative gynaecology should seldom be permitted in the same surgeon in private practice, and that such an operation as ovariectomy should never be performed where patients with uterine cancer or offensive discharges of any kind may pollute the place; and cleansing or purification of the ward or room, of everything about the operation-table or bedding, of the patient herself, and the parts near the seat of operation, of the surgeons, assistants, and nurses, and of all the instruments, sponges, and water used, had gradually become complete before carbolic acid was used." Gentlemen, this would do for part of a clinical lecture on aseptis.

In another place he says he did not attend *post-mortem* examinations, and he advised special operation-rooms for abdominal sections, where dangers of

contact with other patients were reduced to a minimum. He also guarded against contagion being imported by spectators. At that time our knowledge of germs was very small. We only knew they were ubiquitous. Even in the middle of the Atlantic it was said they could be found, but sparsely compared with the myriads prevailing in foul kennels, dirty hospitals, or wherever septic matter abounded. A single germ-obtaining entrance to a wound was considered sufficient to upset matters, and to explain all or any after untoward results. The stoppage of the spray during an operation was looked upon as a calamity, and reserve sprays were kept at hand so that the cloud of carbolic spray that enveloped the seat of operation and everyone who approached it was maintained impenetrable. Wounds and viscera were irritated and chilled by the spray, especially by the foot spray, and no doubt deaths occurred through the action of the spray on the intestines. Sir Spencer Wells used the spray in 1878, but, mark his modification, he put a large sponge over the intestines, so that they would not be injured by the spray. Here again, he seized the weak point and corrected it, and was able to do still better by the antiseptic methods than by his older methods. As surgeons and gynaecologists became accustomed to the improved statistics of antiseptic surgery, so they became dissatisfied with the irritation of the tissues produced by antiseptic dressings, and a variety of antiseptics—enmeshed wools, gauzes, &c.—were tried in succession without arriving at a satisfactory issue. Meantime, the science of bacteriology had developed. Germs were classified; their habits and their habits ascertained, and it became known that there were germs and germs, pathogenic and non-pathogenic germs, that ordinary pure air did not as a rule contain pathogenic germs. Whilst Tait and others were declaiming against the germ theory of disease, because they found they could get good results without carbolic acid, bacteriologists were gradually placing that theory on a foundation of rock, and surgeons were learning that the spray was unnecessary, that there was no use in firing volleys of antiseptics at random here, there, and everywhere, doing as much harm as good. Hence arose the present aseptic system of treating wounds. The aseptic system explains the pre-antiseptic successes of Wells and the rival claims of Tait, Bantock, and all the apostles of cleanliness, who worked well and successfully without admitting the germ theory. I would say that empirically such operators had unwittingly lighted upon the practice of aseptic surgery.

My esteemed predecessor, Professor Taylor, has referred to the aseptic system in terms with which I entirely agree. It is the highest development of the germ theory of disease, and instead of being as some suppose the downfall of Lister, it is his apotheosis. By no class of operators is the aseptic system carried out more strictly and more successfully than by the gynaecologist, and in no region of the body is it more necessary than in the abdominal cavity, except perhaps in the brain cavity.

The old septic surgery which I have described was full of nightmares to the young surgeon, who agonised over each unfavourable symptom in the fear that something he had done was the cause of the trouble. The older surgeons, more hardened, looked upon pyæmia as the visitation of God, and regarded the issue as a perfectly impersonal matter. In antiseptic surgery our nightmares were fewer. The holding out to the end of the operation of the spray producer was one easily avoided by larger boilers and more sprays. The sponges were, however, a real nightmare. The trustworthiness of the nurse who prepared them was most important; many gynaecologists undertook their preparation personally, and the process of cleansing and asepticising them during operation was both complicated and dangerous. A new untried nurse was a terror to us, and often only enabled us to give a divided attention to the details of the operation until satisfied that the new sponge assistant was trustworthy. Then the sponge count and the delay and

exasperation when any sponges were unaccounted for, and the searching until the missing one was found. With the aseptic system the natural sponges have entirely disappeared, and, instead, we have artificial ones, aseptic, dry, and taped, so that they are always to be found whenever wanted. The purification of everything near or coming into the field of operation is more perfect than before, mathematically perfect, as Professor Taylor so aptly terms the asepticity of the sterilised dressings. To the patient aseptic surgery affords greater comfort and safety, to the surgeon more certainty and greater operative success. The æsthetic feelings of bystanders are more considered in aseptic surgery. The surgeon and his assistants in their blood-stained coats or dressing-gowns, gathered round the operation-table, looked like the denizens of the lower regions. Now the white-robed surgeons, their assistants, attendants, and nurses, might be mistaken for angelic hosts. Of course, in all millinery there are fads and vagaries, and operation-room millinery is no exception to the rule. I do not think we should object to any innovation, however bizarre it may seem at first, if it can be shown to help in the better carrying out of the germ theory of disease, and if its disadvantages do not outweigh its advantages. A fad that reduces the mortality will outlive its scoffers and detractors, and custom will soon render it inoffensive to the spectators.

Gentlemen, I feel it to have been a great privilege to have lived in this period of the world's history, and to have come through this experience and watched the development of so many operations from tentative efforts only occasionally crowned with success, and to have seen failures that required a strong heart to persevere and to try again and yet again, in face of the opposition always levelled at innovators up to the time when the results were declared by all to be satisfactory, and the operations took their places as sound gynaecology. Ovaries, uterus, appendages, can now be dealt with safely. Effusions of blood, pus, or serum in the pelvis can now be treated in such a way that the old Latin words, *tuto, cito et jucundo*, may be well applied to the treatment. This knowledge of how to do these things once belonged to a few special men, but has now become diffused through the length and breadth of the country, and the benefits of aseptic gynaecology are brought, as it were, to the doors of the patients. Thoroughly trustworthy and practically perfect operation-rooms are attached to even the smallest hospitals, and the ambitious practitioners of villages are encouraged to prepare themselves for the higher work of the profession. Operations that Wells and Tait talked of with pride, and that were once looked at by lesser men with awe, are now done away in country districts nearly as safely and as well as these operative giants performed them, by comparatively young and inexperienced men fresh from the operation theatres of their student days. At one time our wisest teachers impressed on the students the necessity of attending to the common diseases and to the ordinary methods of treatment in preference to gazing at operations that they would probably never see after leaving the schools, and would much less have in the future any chance of performing. Now, with safe and sanitary hospitals everywhere, cottage or otherwise, every man may become an operator, provided he has prepared himself for that work and is able to take advantage of the opportunities that are now afforded in most localities. I have been surprised at the excellence of the gynaecological as well as surgical work performed in small hospitals, and the valuable assistance that can now be obtained in out-of-the-way places from men whose surgical instincts are kept fresh and keen in their small hospitals, and in striking contrast to men of a more remote date whose surgical training was soon forgotten, and who constitute a danger rather than a help to an aseptic surgeon when their services are the only available assistance upon which he can rely. We have advanced so rapidly in gynaecology that none but the newest editions of the best books are of practical use. An excellent nurse, and up to date when she left

hospital a very short time ago, is now quite behind the times and requires to come back to the wards occasionally to learn the new *technique*. Only the hospital surgeons who live on the top of the waves are able to pick up and use all the treasure trove continually being thrown up from the ocean of truth.

In this rapid retrospect I have referred to the germ theory and the development of its practical application to wounds as the central and main feature of the numerous improvements in surgery and gynaecology that have taken place during my professional life. There are other improvements that have accentuated the success of both the antiseptic and aseptic treatment in gynaecology. Some of them are strokes of genius, so simple and obvious are they, and yet of such sterling value. Foremost among them I would mention the Trendelenberg position in pelvic operations. Whoever has performed or witnessed an operation in a deep pelvis with persistent raids of intestines invading the field of operation in spite of the efforts of assistants to keep them back, their obscuration of the diseased spot, and the necessary stooping over to pierce the depths of a narrow hole to find a bleeding point, must feel thankful to Trendelenberg at every operation he now performs when he sees the intestines rolling back naturally by the force of gravity into the abdomen, the pelvis freed from their presence, and the diseased structures lying exposed, clear and convenient to his manipulations. In all operations in the abdomen, the position of the patient is of primary importance, and the simplicity and ease of all procedures are much increased. When intestinal coils extruded themselves from the abdominal cavity in former times, their return was accomplished by pushing them in, and this sometimes was a difficult and harmful task. Now we take advantage of gravity, lift up the abdominal walls and allow the intestines to flow back unhandled and uninjured. Then with improved clamps and pressure forceps, the hæmorrhage is anticipatory, and the amount of hæmorrhage during an abdominal operation is trifling, and is rarely a factor in the prognosis of the case. The necessity of leaving the peritoneal sac perfect as it exists in Nature is now well understood and always acted upon, but failures to cover raw surfaces led to many fatalities in the past. The avoidance of post-operative hernia by the methods of closing the opening in the abdominal wall, and the value of time in increasing or in diminishing the shock of an operation is so well understood that all surgeons now go straight ahead, using the appropriate means in orderly sequence, so that not a moment is wasted. In a well-regulated hospital a dozen operations may now be done in an afternoon, any one of which would have served our forefathers for the greater part of the time.

It may now be said, What more can we do? Is gynaecology exhausted as a field for enthusiastic and ambitious men? Some years ago I was reading a book on "Exploration of the Polar Region," and I came across a statement by one who afterwards became one of the old sea-dogs of the time of Elizabeth. He joined a ship bound for the Arctic Circle, and the reason he gave as to why he joined that branch of navigation was because all other sciences were shut to him since all possible discoveries had been made both in science and art, and there alone remained, to men of liberal education and leisure who wished to make a name for themselves, the Arctic region and its mysteries. We who know what has happened since then in every science and art know how vain was this statement. Our successors in 2005 may, in reviewing the past, talk about the backward state of surgery in 1905, and of our blindness in not seeing improvements that in 2005 may seem so obvious and so easy. Gentlemen, the history of the past teaches us that if we desire any discovery, and work and watch earnestly and unweariedly for it, that discovery will sooner or later be made. The discovery may not be made by the accredited seekers after it, but it may be by improvements and appliances in another branch of work altogether. How often have surgeons desired to see through the tissues to know where bullets were, and lo! a present

is made to the surgeons by a physicist of the very apparatus desired. We have found the cause of consumption which many generations have desired in vain, we can isolate and cultivate the tuberculous bacillus; that our knowledge does not aid us much as yet in curing phthisis is only a detail which will soon be filled. Without going further into the delightful field of the laws that govern discoveries, let us see what we want as gynaecologists. What are likely to be the fruits of the twentieth century in the matter of diseases of women?

I hope one of the events of the twentieth century will be a lessening of the mortality of cancer of the uterus. According to the Registrar-General in 1902, 3,869 women perished from this disease. Many of them die at an age when a growing family most want their mature wisdom and tender control in launching their offspring upon the world. At the present time the only promising treatment is to remove widely the diseased part. Hysterectomy can now be performed with such a very low mortality that the risks of the operation are small when compared with the results of the disease. Very few cases, however, come into the operator's hands in a sufficiently early stage to test the good effects of early operation. During the six years ending December, 1901, and of which I have the statistics of the female surgical wards of the Liverpool Workhouse Hospital, 98 cases were admitted with inoperable cancer, and died there within a variable time. Several causes may be assigned for the delay. First, the impression often entertained that the hæmorrhage from a cancer is the change of life, that it is hence of no great importance, and will cease spontaneously when the change is complete. Practitioners of medicine in the past often favoured the popular idea and gave ergot, &c., until the condition of the patient made this diagnosis no longer tenable. Secondly, the difficulty of diagnosis in the early stage. Curettings and fragments, when examined by skilled pathologists, generally leave the surgeon in the same state of doubt as he is in from clinical evidence, and if he decides to wait, the patient is so willing that she generally waits too long. Then if the case be still operable and an operation be performed, the disease soon recurs. What we want is a simple and certain test by which *at an early stage* we may recognise cancer and operate in good time. When the disease is advanced the most extensive operations are often worse than useless. Should a woman, æt. 50, have a foul, sanguinary discharge from the uterus, be losing colour, flesh and appetite, I would feel inclined, if the patient and her friends agreed, after full explanation, to remove the uterus freely whilst yet movable, and take the risk of it not being cancerous. The clinical evidence is so much more certain than the microscopical, under the conditions that generally exist in these early cases, that the surgeon would seldom be far out. He would remove safely an organ whose work is done, the existence of which is a menace to the life of the patient. The various organised researches into the nature of cancer that are both numerous and well equipped will perhaps throw some light upon the nature of the disease that our diagnosis will be more trustworthy and our operations more prompt, if, indeed, the cure of the disease will in future be through any operation. I have tested various sera in the treatment of inoperable cancers of the uterus and other places. In one case of cancer of the uterus the disease appeared to be delayed for about a year. At the end of that time it carried the patient off in a few weeks. The microscope did not show any alteration of the usual growths of the cancer cells.

The nervous diseases of women are in a state of great confusion and uncertainty. For instance, one class of gynaecologist may examine a patient suffering from definite pain and symptoms, and declare there is nothing the matter with her except hysteria or neurasthenia. Another may examine the same woman, find a small cystic or fibroid ovary which he may remove, and completely and permanently cure the patient, or the relief may only be temporary, the old symptoms returning perhaps with renewed force, and the patient now able

to blame the operator for all the symptoms she may at any time suffer from. We all know of cases of women who have suffered not only much pain and physical distress from disease, but also great mental distress from being labelled a neurasthenic or a hysterical individual by the doctors, in the first instance, and by their husbands, parents or other near relatives, but in quite a different sense. When a medical man diagnoses neurasthenia or hysteria he knows his patient is suffering from a disease. The friends and relations only understand that she has nothing really the matter with her, that she is a malingerer, a humbug, a teller of untruths. The confidence and affection of married life is destroyed, and the results in family life are deplorable. These diseases require careful study, they require to be classified and their treatment formulated. Were this done, many brilliant women who fizzle out into hopeless invalids would be saved to themselves, their families, and friends.

Uterine displacements arise most frequently after strain, miscarriages, and confinements, and in the early stage these misplacements are capable of replacement and probably of permanent cure. Is our treatment at the present time a rational one, and would it be tolerated in other displacements? A woman has a miscarriage, the fœtus has come away, the hæmorrhage has ceased, and the convalescence is uneventful. How often is it the custom to keep the patient in bed on her back for two and three weeks, then allow her to get up and go about until she begins to complain of pains and dragging, and then a fixed incurable retroflexion is found, and perhaps an operation is necessary to cure her. In such a case the uterus has only developed in the fundus. When the contents are expelled, the fundus is enlarged and the cervix is soft, top heavy and falls back, the intestines roll in front of it—that is, on the anterior or inferior surface instead of the posterior or upper. The patient is kept on her back, a position that tends to retain and to increase the displacement. After the fortnight or three weeks of the dorsal position, the patient is allowed up, the uterus is at this point in a state of retroversion, the erect position and the pressure of the abdominal viscera upon the fundus, together with the relaxation of tissues due to the rest, soon produces the pathological retroflexion that by its symptoms demands the attention of the gynæcologist. More minute attention to the condition of the uterus would detect the threatened displacement soon after its occurrence. Simple reposition would probably cure many incipient cases. With the prone or semi-prone position maintained while necessary, other cases would be cured. The assistance of a Hodge might be required in others. The erect position is the most secure one for a healthy uterus, as that organ then lies well forward on the bladder with the pubic symphysis beneath, and both its utero-sacral and round ligaments are in a healthy state of action and interaction. But what do we see in practice? Women who are supposed to have a tendency to displacement sit down at every opportunity if not all day long on a comfortable reclining chair or sofa and put their feet up, the best possible position for relaxing all the muscles and allowing the uterus to slide down to the bottom of the pelvis. It gives relief, I grant you, but it perpetuates and accelerates the tendency to displacement. After confinements, abortions, strains, any changes in the position of the uterus should be looked to just as carefully as we examine fractured bones, and reduction should be effected and maintained at the earliest possible moment. The causes of many cases of displacement are involved in obscurity, and urgently require elucidation.

Gentlemen, in this imperfect sketch of my experience of the rise of gynæcology, I have omitted two circumstances that fostered the growth of the specialty most materially—I mean the foundation of the British Gynæcological Society and the influence of its *Journal*. The Society has brought men of like instincts together, where due time is obtained to discuss their common scientific interests, and the valuable *Journal* has carried these discussions to a wider circle than are able to

attend the meetings. The choice gleanings from other journals are most useful, and I have often obtained valuable information as well as inspiration from its pages. May it be said of both the Society and the *Journal*—

“That which they have done is but earnest of the things that they shall do.” Longfellow tells us how to do it:

“Let us then be up and doing,
With a heart for any fate,
Still achieving, still pursuing,
Learn to labour and to wait.”

A NOTE ON

ANTE-MORTEM CLOTTING IN THREE OF THE CHAMBERS OF THE HEART, AND OTHER CASES OF CARDIAC THROMBOSIS.

By F. PARKES WEBER, M.D., F.R.C.P.,

Physician to the German Hospital, and to the Mount Vernon
Hospital for Chest Diseases, Hampstead.

THE patient, K. Tr., a somewhat thin and anæmic-looking man, æt. 45, was admitted under my care at the German Hospital on October 6th, 1904. The history was that for eight days he had had some œdema of the legs, and for three days had been oppressed with dyspnoea and cough. During the last six months he had been much troubled with pains in the gastric region, and during that period had become decidedly thinner. Twenty years ago he had been laid up with a severe illness, apparently typhoid fever, in a hospital in Germany. Otherwise he had always been well, and he denied excess in alcohol. He had been married fourteen years and had had five children, three of which were living. One of his parents died at seventy-eight years of age; the other was still living, aged seventy-two years.

In the hospital the patient was found to have enlargement of the heart and liver. The cardiac impulse was diffused and could be felt two inches outside the nipple line; there was no murmur. Wheezing sounds were heard over the lungs. The patient's expression was anxious and pinched, as it often is in myocardial affections. There was slight œdema. The urine was at first about normal in quantity, of specific gravity 1020, and containing a trace of albumin and a sediment of urates; hyaline casts were detected. Afterwards albumin was sometimes absent.

The patient was treated by rest, and drugs such as strophanthus, digitalis, squills, &c., were tried, but his condition gradually became worse. There was a good deal of pulsation in the jugular vein. Never any fever. On November 30th the pulse could hardly be felt at the wrist, there was more cough, and crepitations could be heard all over the lungs. He died on the afternoon of December 2nd, 1904.

At the *necropsy* the heart weighed twenty-four ounces and all its chambers were dilated. There were a few epicardial petechiæ about the apex. No pericarditis. There was partly decolorised *ante-mortem* thrombus in both ventricles, chiefly near the apices and in the right auricular appendix. The left auricle was free. There was no valvular disease except some old thickening of the mitral cusps. Part of one of the trabeculæ in the left ventricle was calcified. The great dilatation of the right auriculo-ventricular orifice accounted for the jugular pulsation observed during life. The coronary arteries were in places slightly atheromatous and stenosed, but, on the whole, not greatly

diseased and not thrombosed. The aorta showed moderate atheromatous changes. Microscopically the walls of both ventricles showed a diffuse chronic interstitial fibrosis with degenerative changes in the muscle fibres.

There was moderate hydrothorax on both sides and some ascites. No pleurisy. The lungs showed the changes of chronic bronchitis, but no embolic infarctions. The liver weighed sixty-two ounces, and both macroscopically and microscopically was a typical "nutmeg liver." The spleen weighed six ounces, and was of the "cardiac" type, of red colour and firm consistence, but without embolic infarctions. The kidneys weighed together ten ounces and showed the remains of old embolic infarctions, so old, in fact, that, owing to atrophy of the scar tissue, the infarctions were represented almost only by depressions. The capsules stripped readily, and microscopical sections of parts of the kidney not affected by the old embolisms showed practically nothing abnormal beyond passive congestion. The stomach exhibited the ordinary catarrhal changes and a few hæmorrhagic spots in the mucous membrane, such as are found in cases of great passive congestion. The small intestines showed similar changes. In the duodenal mucous membrane, near to the bile papilla, was a small oval nodule, measuring about 2 X 3 mm., which by microscopic examination (a) appeared to consist of sclerosed pancreatic tissue, similar to the aberrant pancreatic tissue in the intestinal walls described by E. L. Opie (b) and others. Near this spot there was a little hæmorrhage in the connective tissue between the head of the pancreas and the duodenum. The suprarenal glands showed nothing special. The bone-marrow of the shaft of one humerus was examined and found to contain red patches, probably due more to congestion and hæmorrhages than to lymphoid metaplasia.

In this case the presence of "cardiac anxiety" and dyspnoea contrasted with the relative absence of certain signs usually associated with chronic cardiac failure, such as œdema and diminution of the quantity of urine. Clinically, the possibility of cardiac thrombosis was thought of. It seems remarkable, however, that the clots in the chambers of the heart gave rise to no pulmonary or other embolisms. The scars resulting from embolic infarctions in the kidneys were of much earlier date, and perhaps, taken in connection with the old thickening of the mitral valve, were to be attributed to a former rheumatic endocarditis, of which we got no history, but which may have been contemporary with the commencement of the chronic interstitial myocarditis ("myofibrosis cordis"), a cause of cardiac dilatation and cardiac failure much more talked of than actually seen.

In 1897 I described the case of a man aged fifty years (c) with mental hebetude and cardiac failure. After his death the heart was found to weigh twenty ounces; it was dilated and contained granular thrombus in three of its chambers, namely, as in the present case, in both ventricles and the right auricle. The cardiac valves showed

no disease excepting slight atheromatous changes. There was no history of great indulgence in alcohol. Of the four cardiac chambers it is probable that the left auricle (a) is the one in which *ante-mortem* thrombus least often forms.

These cases differ somewhat from those of globular thrombi with subtrabecular ramifications, (b) of which I had a typical example in 1902. The patient was a woman, æt. 42, with an aortic diastolic murmur, who had suffered from articular rheumatism when twenty years old. A few months before her death she began to suffer from attacks of "thoracic anxiety," with dry cough and feeling of being suffocated. In the hospital she had frightful paroxysms of dyspnoea, and had blood-stained expectoration. Resonance was impaired over the base of the right lung, and crepitations were heard over both bases. There was slight fever at the end. After death the heart was found dilated and weighing sixteen ounces. The left ventricle was hypertrophied, and the aortic semi-lunar valves were thickened and contracted. A number of somewhat globular or faceted thrombi, varying in size from a small pea to a large hazel-nut, were attached to the trabecular meshwork of the right auricle (chiefly the auricular appendix). The liver and other organs showed signs of chronic passive congestion and a considerable portion of the lower lobe of the right lung was solid (embolic infarction?). The globular thrombi in the auricle consisted of an outside shell (doubtless fibrinous), filled with a reddish, thick creamy ("puriform") material, which under the microscope was seen to be granular debris with an admixture of white cells. Much has been written by Bristowe (c) and others on softening clots of the heart. Perhaps the central softening which so often occurs in globular thrombi is due to the infiltrating leucocytes exercising a digestive or proteolytic action on the clotted blood. In regard to this softening of cardiac thrombi, Mr. Shattock has kindly directed my attention to the softening which Mr. C. A. Ballance (d) found to occur in the interior of aseptic thrombi after ligation of blood-vessels.

Therapeutic Notes.

APPENDICITIS AND MINERAL APERIENT WATERS.

By DAVID WALSH, M.D. Edin.,
Senior Physician, Western Skin Hospital, London, W

At the present time appendicitis is the subject of great public interest and curiosity. On all hands the medical practitioner is assailed by questions as to its origin, its course and its treatment. Its very name has been abandoned by some surgeons in favour of perityphlitis. Curiously little is really known as to its ultimate causation, although the general conclusion appears to be that the localised inflammatory process is of microbial origin, and that, again, is connected with constipation as a precedent or associated condition. Few pathologists probably would venture further than that in our present state of knowledge. Yet there are plenty of writers ready to rush in where "angels fear to tread." The public

(a) I have to thank the house physician, Dr. Blendinger, for microscopic sections of the organs.

(b) "Diseases of the Pancreas," 1903, pp. 46 *et seq.* J. H. Wright ("Journ. of Boston Soc. of Med. Sciences," 1901, vol. v, p. 487) describes a small "aberrant pancreas in the region of the umbilicus," removed by operation during life.

(d) "Ligature of the Great Arteries in Continuity," 1891.

newspapers and journals have been flooded with all kinds of grotesque and fantastic literature upon the subject of appendicitis, not infrequently above the signature of a medical man. A curious production of the kind appeared lately in one of the most famous of our monthly reviews. (a)

The author of the remarkable article in question announces as one of the chief causes of appendicitis the use of "Hungarian waters, aperient salts, and liver pills." His absolutely gratuitous assumption is based on an equally improved theory of the action of saline purgatives, namely, that the watery flow leaves solid matter behind to accumulate in the cæcum, and, by subsequent putrefaction, to set up inflammatory mischief in the neighbourhood of the appendix. As a matter of fact, solid accumulations in the cæcum are rare under any circumstances, and although small fæcal concretions are sometimes found in the vermiform process in appendicitis, yet they are, on the other hand, just as often conspicuous by their absence.

Appendicitis, again, is three or four times more common among men than among women. But women are more prone to constipation, and, therefore, use more aperients; possibly the latter fact accounts for the lesser incidence of appendicitis upon their sex. Any way, the sex-incidence alone is sufficient to upset the writer in the review, not to mention the further fact pointed out in the *Lancet*, (b) namely, that the age at which the malady usually occurs is from ten to twenty years, which is not the period of life at which purgatives are generally taken. On such scant foundations as those above indicated it seems incredible that a medical writer should condemn the use of aperients.

As a matter of fact, it is likely that aperients, especially the Hungarian bitter water which the writer so much resents, form the best preventive treatment of appendicitis. In a host of cases of chronic or recurrent constipation the morning draught of Hunyádi János forms the sheet-anchor of the medical attendant. From every point of view the wholesale condemnation of so valuable a remedy in the pages of a prominent review is much to be regretted. The harm that may be effected by the circulation of such statements is incalculable. It is a thousand pities that a responsible lay editor should have permitted a technical theory of this kind to appear in his review. Its fitting place for publication would have been one of the medical journals, where it would have been duly weighed in the professional balance, and its claims to consideration promptly decided.

But it is not only by way of prevention that mineral waters such as Hunyádi are valuable. As every practical physician knows, they constitute our great therapeutic weapon in the large class of cases where the symptoms are early and mild, and where it is reasonable to anticipate relief or cure without the aid of the surgeon. In such cases a wineglassful of the aperient water can be given every morning. In cases where appendicitis has shown itself, but has not recurred, the same remedy can be used every other morning for months together. In recurrent cases the question of operation always demands most serious attention. As a preventive measure in cases of chronic constipation a similar course

can be adopted. Something of the kind is specially indicated when examination shows the blood to be defective, or when the patient suffers from dyspepsia or other gastric troubles, or is engaged in a sedentary occupation. To a certain extent the use of a natural saline aperient water may be made to compensate unfavourable conditions in the individual, as, for instance, over-feeding, excess in alcohol, want of exercise, the gouty or rheumatic habit, and, generally speaking, depressing or harmful factors of the modern civilised environment which are prone to lead to impairment of the ordinary physiological functions of our daily life.

Clinical Records.

CASES OF FIBROMA AND OF CARCINOMA OF THE OVARY. (a)

By H. MACNAUGHTON-JONES, M.D.

Fibroma of the Ovary.—A specimen of true fibroma of the ovary was shown to the Gynæcological Society on February 9th. It was removed from a patient, æt. 38, who suffered from ascites. As a tumour could be felt through the vagina, abdominal exploration was advised. The patient was very obese, and on evacuation of the ascitic fluid, a large and hard liver was found. On examination of the pelvis, the ovarian tumour was discovered at the left side. The Fallopian tube was unaffected, and the uterus was healthy, as were also the adnexa of the opposite side. The following was Dr. Cuthbert Lockyer's report:—

"The tumour is a typical fibroma growing from the outer pole of the ovary. It is composed of interlacing bundles of dense fibrous tissue showing very distinct nuclei. The inner pole of the gland presents a stroma of varying consistence, thick-walled blood-vessels, small cystic spaces, several corpora albicantia, but no normal-looking Graafian follicles."

The tumour agreed with the description he (Dr. Macnaughton-Jones) had given in the last edition of his work, namely, "a smooth, lobulated mass, greyish-white or marbled, rarely dotted with cystic degeneration." It would be noticed that at one end of the tumour as shown by the microscopical sections on the table, there were some cystic spaces. The tumour had no proper capsule in the ordinary acceptation of the term, as, for instance, in uterine fibroma, the tunica albuginea being involved in, and incorporated with, the growth. As usual, only one ovary was affected, and the tube was healthy. The exact source of origin of these tumours appeared to be uncertain, but it was thought that the growth commenced in the embryonic tissue round the follicles. The tumours were usually small, as in this case, the larger sizes being of a fibro-myomatous nature. Up to 1902 Peterson had collected some 82 cases. Dr. Macnaughton-Jones has met with one other instance of true fibroma, the particulars of which he had brought before the Obstetrical Society, and which had been recorded in his work. The ascites in this case was, he believed, caused by the hepatic affection, and had nothing to say to the fibroma.

Carcinoma of the Ovary.—The patient from whom the tumour was removed was æt. 45. She was a nullipara, married for twenty-five years. One brother had died of cancer at the age of forty. The patient had always been a robust woman, and there had been no symptoms of any kind calling for special comment up to a period within six weeks of her operation. She then had an attack of parametritis, when a myomatous uterus was discovered, reaching about half-way to the umbilicus. For this she was treated, but her symptoms continuing, an examination under anaesthesia was made some three weeks subsequently, when a mass was found towards the left side, which was believed to be a pyo-salpinx. There was nothing in the appearance of the patient or her condition

(a) *Nineteenth Century*, January, 1905.
(b) *Lancet*, February 11th, 1905, p. 872.

(a) Notes read at the meeting of the British Gynæcological Society February 9th, 1905.

to suggest malignancy. There was pain, but it was not severe. The catamenia during the last two years had been uncertain, the last period having occurred three weeks previous to the onset of her inflammatory attack, and the one before that ten months previously. A severe attack of peritonitis ensued in the fourth week of her illness, and on its subsidence he operated. The tumour was found behind the myomatous uterus, to which it was adherent, as also to all the surrounding structures. Its isolation and removal were very difficult but were successfully accomplished without accident. The tumour was then found to be the ovary, the centre of which had necrosed and broken down into pus.

"The specimen was a very degenerate carcinoma of the ovary. No part of the tube could be found in the necrotic mass. Microscopically, there was a stroma of fully formed fibrous tissue. In the latter there were alveolar spaces in which the carcinomatous cells were packed. Most of the latter were degenerate and shrunken."

There did not appear to be any involvement of the surrounding parts, nor of the opposite adnexa. The patient stood the operation well under chloroform anaesthesia, but the temperature range only twice reached the normal line, and notwithstanding injections of artificial serum and strychnine, with other measures, she died within sixty hours after the operation. Her condition was, of course, desperate before its performance. The noteworthy feature of the case was the complete absence of symptoms, and the apparent good health of the patient up to so recent a period. Mr. Charles Ryall had rendered him valuable assistance during the operation.

Transactions of Societies.

ROYAL ACADEMY OF MEDICINE IN IRELAND.
SECTION OF OBSTETRICS.
MEETING HELD FRIDAY, FEBRUARY 3RD, 1905.

The PRESIDENT in the Chair.

SPECIMENS.

DR. ALFRED J. SMITH showed a rare specimen—a large physometric uterus. The patient was delivered early in last October of twins (at the sixth month), both dead, and beginning to decompose. On the fourth day after delivery she had a severe rigor, with temperature of 106° F. Her local doctor washed out the uterus with a weak corrosive sublimate solution. Notwithstanding this, her condition went from bad to worse. On admission to St. Vincent's Gynaecological Department she was in evident distress from distension—temp. 102.6°; pulse, 120. Examination under ether was unsatisfactory, as nothing could be mapped out. The diagnosis was not made until the abdomen was opened. The numerous discoloured, gangrenous-looking patches which were demonstrated influenced the decision in favour of removal. A hysterectomy was performed, fortunately without rupture. Examination of the contents was postponed, as Dr. Smith wished to show the large uterus in its distended condition. Uninterrupted recovery.

DR. KIDD wished to know how the gas had been kept in the specimen? The only similar case he had seen was an accumulation of gas inside a gestation sac. The patient came into hospital three months pregnant, with symptoms of threatened abortion. The symptoms abated, and she went out. He saw her again when she was thirteen months pregnant. The whole of the front of the abdomen was perfectly dull. A rectal examination was made, and next day her temperature was 104°, and the abdomen very resonant. An operation was performed, and it was found that there had been a primary rupture into the layers of the broad ligament, and the gestation sac had gone on developing. There was an escape of very offensive gas on the sac being opened. The patient made a good recovery, and had had two children since. The only explanation

he had for the formation of the gas was that the bacillus coli communis had got into the gestation sac on account of the rectal examination.

DR. PUREFOY said that most of them had seen the condition termed physometric in connection with malignant disease, or in cases of delayed or neglected labour, where air had got into the uterus. Dr. Smith's case was remarkable on account of the gas having remained in the uterine cavity.

DR. E. H. TWEEDY showed an ovarian cyst.

DR. PUREFOY read a paper on

TWO CASES OF CYSTIC ENDOMETRITIS, WITH REMARKS ON TREATMENT.

DR. HASTINGS TWEEDY said that cystic endometritis was a disease he did not know personally, and of which he could find no account. He objected to fresh nomenclature, and thought they should stick to the term glandular. His objection to the term "cystic" was that it did not lead anyone to a knowledge of what one was dealing with, whilst "glandular" did. The question of treatment was more interesting. A few years ago every case was curetted, but of late there had been a reaction against this, and many now preferred to use intra-uterine douches, caustics, &c. He protested against this, and believed that in his study practice the surgeon had little right, and rarely necessity, to pass anything into the uterus. It was impossible to be aseptic in study practice. The vast majority of cases of endometritis, especially the hypertrophic form, were cured by one cleanly curetting. He left his cases alone after curetting, and did not use medications subsequently. He washed out the debris with salt solution, and did not use antiseptics, which devitalised the tissues, and the less the uterus was irritated with them the better. He could not understand the *raison* of taking a patient in every third day to inject iodised phenol after curetting; it seemed to him unnecessary and dangerous. The less often the uterus was entered the better. There was a certain amount of danger in putting anything into it, and if good results were obtained without caustics, why apply them? The term "benign adenoma" is misleading, as it implies growth accompanied by increase in the number of glands, and all such growths of the endometrium will prove in practice to be malignant.

THE PRESIDENT said he divided endometritis into glandular and interstitial. There were two kinds of glandular—hyperplastic and hypertrophic. Hyperplastic was adenoma, and in it there was an enormous increase in the number of glands: hypertrophic had a normal number of glands, but greatly increased and distended, and which, when occluded, formed cysts. The hyperplastic frequently became malignant, therefore these cases had to be seen often, and the uterus removed. The hypertrophic might be merely distended tubes, or, if seen late, cysts. The treatment was to mechanically remove the mucous membrane, and try to cultivate a healthy mucous membrane. Try to find out the cause of the endometritis. His practice was to curette and wash out once, and wash out again on the third and fourth day to see that nothing was left behind. He used hot sterilised saline solution, and did not employ any intra-uterine medications.

DR. PUREFOY, in replying, said he thought it was of importance for them to study the pathology of these conditions for themselves, and if systematic examination were made in every case good practical results would follow. With regard to the objection to giving the condition a special name, he could not agree with Dr. Tweedy. The condition was one of considerable rarity, and most of the manuals did not allude to it at all. He believed that the condition was not a very advanced stage of glandular endometritis. He did not know what caused it, but thought that if it had been at all common, he would have met with more than two cases of it. The term cystic endometritis was employed in two classes of cases—in gynaecological cases, where the patients were not pregnant, and also a diseased condition of the endometrium occurring in pregnant women. His cases occurred in women apart from pregnancy. The epithelium in the dilated glands was not

in the atrophied condition you would expect it would be from pressure; it was intact. He believed the condition was very rare. With regard to subsequent treatment, he thought it was in the patient's interest to use a mild caustic four or five days after curetting, and its subsequent use was to be determined by the amount of discharge, condition of cervix, character of first menstruation, &c.

OBSERVATIONS ON BOSSI'S DILATOR, WITH NOTES OF FOUR CASES.

Dr. ALFRED J. SMITH set out the views of the rival schools which indicated that Bossi's dilator had not met with universal approval or adoption. He considered it to be the duty of each to assist in determining this question—what is the place this dilator holds in an armamentarium. Dr. Smith is convinced that, within certain well-defined limits, it has a distinct position, but these limits must be clearly defined. Of his four cases—three for eclampsia and one for placenta prævia—all were successful; the entire time between the introduction of the dilator and the end of the third stage did not exceed one hour. There was an extensive laceration of the cervix requiring stitches in the placenta prævia case. He considers Bossi's dilator dangerous when the cervix is long, and not taken up, especially in cases of placenta prævia. The close proximity of the uterine sinus adds a new danger should the laceration unfortunately extend to or open them up. He dwelt on and discussed the question of dynamic action. One great difficulty confronted him—how much dilatation would be necessary to deliver the foetal head at the sixth or seventh month? And in order to formulate a basis for accurate observation, he drew up a scale for his guidance based on the relative circumference of the S.O.B. diameter during these months.

Dr. KIDD said that one disadvantage of Bossi's dilator had been met by changing the number of blades from four to eight, thus having eight points of pressure on the lower zone of the uterus, and less probability of rupture. An advantage of Bossi was that you could watch digitally the amount of tension between the four blades, which was hardly possible when eight blades were introduced. Another objection was that the angle at which the dilator was set to the shaft was not the angle at which dilatation would take place. Seigneux tried to meet this objection in his dilator, but it had its disadvantages also. There was too much resiliency in the lateral blades, and in order to try and gain the advantages of having eight blades you had to change the blades and insert blades with broader flanges, and this was a very troublesome proceeding. He was quite sure that where mechanical dilatation was used for placenta prævia, the risks of laceration were greatly increased. He certainly thought that its use in eclampsia would give happy results.

Dr. FITZGIBBON said he had used Bossi's dilator in a case in which he had induced labour at seven and a half months. He started by using bougies, but the uterus took on no action, and they were introduced again the day following. The membranes had then ruptured, and the following morning he decided to dilate the cervix, into which he could introduce two fingers. He dilated up to 7 cms. He did not intend to complete delivery, and left the patient, having put some gauze in the cervix. Labour set in in three hours, and she was delivered three hours afterwards. He considered that labour had been induced by mechanical dilatation, which started uterine action.

Dr. HASTINGS TWEEDY said he could hardly think that dilators had been responsible for the salvation of even one woman. Medical papers nowadays teemed with the praises of mechanical dilatation of the cervix in the treatment of eclampsia. He had treated within the last fifteen months ten cases of puerperal convulsions in the Rotunda Hospital with one death; in this case the diagnosis of eclampsia was doubtful. In a large number of these, it was observed that convulsions became severe after the birth of the child, so that the emptying of the uterus could not be considered a save-all and cure-all. In but one of the suc-

cessful cases was delivery accelerated even by forceps, in the others labour was allowed to go on naturally, and finish. These results show that recovery will take place even though violent means to extract the foetus are not adopted. As to the dilator's usefulness in ante-partum hæmorrhage, due to placenta prævia, he must dissent from the views of those who recommended its employment; in such cases the cervix often tears without one being conscious of the fact. The treatment could never compare favourably with the plan of bringing down the leg and leaving the case to Nature. The cervical epithelium is bruised during the process of forcible dilatation, and such bruising predisposes to sepsis. There was one class of case in which he thought the dilator was sure to be applied—"rigid os"—but its use in such cases was sure to be repented of. Bossi himself counted the condition as a contrary indication. Seigneux's instrument appeared to have some slight advantage over the other dilators; but if one desired to open the cervix, it could easily be accomplished by any one of the lacerating instruments at present on the market.

Dr. PUREFOY said that the range of utility of a dilator was not at all as wide as they had been led to believe. The utmost caution was necessary in its use, and the cervix was often found lacerated without it having been noticed. In cases of eclampsia it might sometimes be of use, but the number of cases was very small. It was useful in cases where labour had started, and the pains had come on and afterwards stopped.

The PRESIDENT, in replying, said he had tried the dilator, having heard and read so much about it. He thought that it was in places like Dublin that the principles of new inventions should be tested, as they had to report on them to country practitioners. As to its use in eclampsia, he thought that certain cases would get well no matter what form of treatment was used.

BRITISH GYNÆCOLOGICAL SOCIETY.

MEETING HELD FEBRUARY 9TH, 1905.

Dr. WILLIAM ALEXANDER, President, in the Chair.

Dr. MACNAUGHTON-JONES showed a specimen of Fibroma of the Ovary and one of Carcinoma of the Ovary, and read notes, which will be found on page 187.

Dr. HEYWOOD SMITH asked for an explanation of the absence of the capsule in the first specimen. Had it become involved in the fibroid degeneration?

Mr. CHARLES RYALL, who had assisted Dr. Macnaughton-Jones in operating on the second case, alluded to the very extensive intestinal adhesions, and mentioned a case in which he removed an ovarian tumour with cystic degeneration from a woman fifty years of age, who was suffering from intestinal obstruction. He found secondary deposits in the ileo-cæcal valve.

Dr. HUTCHINSON SWANTON said that the frequency with which ascites was associated with solid ovarian tumours was well known, but in 1902 Demons, of Bordeaux, had reported cases in which there was extensive effusion of fluid, the patients were reduced to the last extremity when the abdominal cavity had been explored, and a fibroma of the ovary detected and removed, the patients recovered. He asked whether there had been any fluid in the pericardium or pleura in Dr. Macnaughton-Jones' case.

Mr. BOWREMAN JESSETT said that some years ago Mr. Lawson Tait asserted that out of every ten ovarian or abdominal tumours with marked ascites, nine were malignant, and he had himself seen a large number of cases of that description. On the other hand, fibrous tumours were seldom accompanied by ascites.

Dr. INGLIS PARSONS said that in two cases the ascites had been so enormous that the diagnosis made had been ovarian cystoma; indeed in all malignant abdominal tumours he had seen there had been ascites except in one, an ovarian tumour not adherent, and removed quite easily. Rapid recurrence took place,

and the woman died in a fortnight. The tumour was a sarcoma.

Dr. MACNAUGHTON-JONES, in reply, said that there was no capsule to the fibromatous tumour in the true sense of the word "capsule," the tunica albuginea being incorporated with, and involved in, the fibrous tissue of the tumour. There had been no pelvic pain. The ascites, he considered, had nothing to say to the tumour, but was due to the condition of the liver, which he considered to be an alcoholic one.

In the case of the carcinoma, neither the uterus nor the ovary was involved, and he believed, though there was no opportunity of having an autopsy, that the change was a primary one in the ovary. The absence of ascites was noteworthy, though he had seen different cases in which this condition was absent. It should be remembered that in different forms of cystoma, especially in those of a multilocular colloid nature, and not malignant, if there were any escape of the contents of the cyst into the peritoneal cavity, a certain amount of ascites was generally present. As to the adhesions, the tumour was firmly embedded in these, and on its removal the rectum and cæcum were exposed, the tumour having to be stripped off these.

The PRESIDENT then delivered his Inaugural Address on the "Rise and Progress of Gynæcology," which will be found on page 181.

Mr. BOWREMAN JESSETT, in proposing a vote of thanks to the President, referred to some experiences that illustrated what the President had said. Some years ago, about the "fifties," when he was a house surgeon, it was never thought that the abdomen should be explored. The peritoneum itself was a sacred membrane which nobody encroached upon. He remembered performing his first ovariectomy in the early seventies, in a case of cancer. The ligature he used consisted of a thick whip-cord; the patient did remarkably well, and returned to her work in the fields. Dr. Macnaughton-Jones had referred to the association of malignant cases with ascites. That woman had some ascites, and it was a case of colloid. But she died twelve months afterwards with recurrence of the disease all over the peritoneum. He recollected another interesting case in the early sixties, when first ovariectomy was coming to the fore. In University College Hospital numerous foreigners came to see a very interesting case of supposed ovarian cyst. This went on for some few weeks. On one occasion the physician asked two French physicians to "come and see an interesting case of ovarian cyst in the hospital." In due course he went to the bed where the patient had been lying, but she was not to be found. "Where's my patient?" he asked. "She is in a private ward." "What for?" "She has been delivered of a fine son this morning!" The diagnosis in that case had not been very complete, and he did not think the case was communicated to the foreign physicians. In conclusion, Mr. Jessett remarked with regard to malignant disease of the uterus that if only they could get some simple test by which to diagnose the disease early it would be a good thing. For his own part, he much preferred to remove the uterus and find it was not malignant than to leave doubtful cases alone.

Dr. MACNAUGHTON-JONES, in seconding the vote of thanks, remarked that he had himself passed through all the phases of Listerism, to the modern complete aseptic methods, from the period of Lister's original antiseptic putty, which he had used in some of his own earliest amputations. While it was interesting to trace the progressive development of aseptic surgery from the rougher methods of our ancestors, still, we should not forget how much we were indebted to them for the boldness and skill with which, under great disadvantages, they had accomplished all they had. Dupuytren had said, in the Academy of Medicine at Paris, that the man who performed ovariectomy should be indicted for manslaughter, yet we owed a great deal to Dupuytren. Their President was universally known, and in every foreign clinic his name was in daily use

in connection with the well-known operation associated with it.

THE LARYNGOLOGICAL SOCIETY OF LONDON MEETING HELD FEBRUARY 3RD, 1905.

Mr. CHARTERS SYMONDS in the Chair.

CASES AND SPECIMENS.

Mr. C. PARKER showed a case of Tuberculosis of the Larynx in a woman, æt. 31. The disease commenced during her fourth pregnancy, since which she had been pregnant five times. On three occasions the child was born alive, and on two occasions she had miscarriages.

Mr. CLAYTON FOX showed, for Dr. Frederick Spicer, a case of Diffuse Papilloma of the Vocal Cords; and Dr. Edward Law showed a man, æt. 69, from whom a laryngeal growth was removed twenty-one years ago from the right vocal cord by the late Mr. Whistler. Views as to the present condition were invited. Some members were of opinion that the case was malignant, but the general feeling was that this was not so.

Mr. DE SANTI showed two cases: A woman, æt. 30, shown at the last meeting, with a laryngeal swelling which was thought to be tuberculous, but a microscopic slide since showed that it was undoubtedly squamous-celled carcinoma. The second case was that of a man, æt. 60, with a large mass of malignant glands in the neck, and swelling of the larynx on the same side.

Mr. STEPHEN PAGET showed three cases for diagnosis. The first was a case of fixation of the left vocal cord, and the opinion of the meeting was that this was aneurysm. The second case was one of growth of the right ventricular band. The third was one of growth in the larynx, which was generally regarded as papillomatous, though some members inclined to the view that it was malignant.

Mr. F. J. STEWARD showed a case of Recurrent Ulceration of both Tonsils associated with Lymphadenoma, in a woman, æt. 64.

Dr. F. W. BENNETT showed a specimen and photographs of a Malignant Growth of the Larynx, and a case of nasal ulceration of the septum, for diagnosis. The latter was considered to be a case of ethmoiditis.

Dr. HERBERT TILLEY showed a case of Primary Sore on the Tip of the Tongue in a man, æt. 40. There was slight enlargement of the glands, but no rash. Some doubt was expressed whether it might not have been a simple sore resulting from the irritation of the caustics which the patient had repeatedly applied. It was advised that the patient be put upon antiseptic treatment, and the case reported on further.

Dr. G. CATHCART showed two cases: First that of a patient shown at a previous meeting, Pachyderma Laryngis (? tuberculous), the second being a case of combined Functional and Organic Paresis of the Larynx in a singer, æt. 34.

France.

PARIS, February 18th, 1905.

TREATMENT OF PHLEBITIS.

Dr. MARCHAIS, who has particularly studied the above malady, recommends the following treatment: Absolute immobility during the period of fever and for a fortnight after it has disappeared. During this time the temperature must be taken regularly, and if the fever returns another fifteen days' rest must be observed, after which massage and slight movements of the limb may be ordered. For the first five days, passive movement of the toes and foot are made, and the massage should consist of very slight rubbing of the limb without pressing on the veins or removing the leg from the bed. On the fifth day the patient can make the movements himself, and at the end of the first week the muscles can be subjected to the massage, in respecting the region of the large veins. In the following

week the patient can be allowed to sit up in bed and towards the fifteenth day he may take a few steps.

DEAFNESS FROM LESIONS OF THE INTERNAL EAR.

Three signs exist which characterise lesions of the internal ear—vertigo, subjective noises, deafness. Dr. Chavanne gives the following advice for the diagnosis and treatment of this affection:—

If the deafness sets in almost suddenly, it may be the consequence of traumatism, syphilis, or, on the contrary, to some morbid condition such as diabetes, nephritis, mumps, &c. Two varieties of traumatism of the labyrinth may be met with—commotion and wounds; the deafness due to the former may be either temporary, tenacious, or even incurable. Rest in bed and perfect quietness is the best treatment. If after two days improvement is not observed, revulsion should be made over the mastoid process or leeches applied, and at the same time a purgative given and the feet put into a mustard bath.

If at the end of four or five days the deafness persists, the auditory nerve should be stimulated by injections of strychnine subcutaneously.

Nitrate of strychnine, 0.20 grammes;

Distilled water, 10 grammes.

From 2 to 6 drops (2 to 6 milligr. of strychnine) injected each day for twelve days under the skin of the back of the neck. If at the end of this time the audition is improved, the injections will be continued; if not, they will be suppressed. The deafness is incurable.

If the deafness is due to a wound, it must be treated antiseptically, in order to avoid subsequent inflammation of the membranes of the brain. Where syphilis is suspected, either acquired or hereditary, large doses of the specific treatment must be given. In acquired syphilis, it is in the tertiary period that lesions such as periostitis and exostosis are found in the labyrinth. The deafness is generally bilateral. Hereditary syphilis is one of the greatest enemies of the ears and is an important factor in the causes of deaf-mutism.

Where the deafness is due neither to traumatism nor syphilis, and it has become chronic, the best treatment is that of injections of pilocarpine. This substance favours the resorption of the exudation contained in the labyrinth by the intense sudation it provokes. Subcutaneous injections are generally preferred.

Hydrochl. of pilocarpine, 0.20 grammes;

Sterilised water, 10 grammes.

One drop corresponds to one milligr. of the active substance, and 15 drops should never be exceeded.

The patient will be given the injection, rolled in a flannel blanket. The injections should be given fasting, as besides sweating the drug produces nausea.

When the sweating ceases, the patient should dry himself thoroughly to avoid cold, and resume his ordinary occupation. The injections will be repeated every two days until a series of twelve have been given. If after this time no improvement is observed, the deafness is incurable.

When the deafness comes on gradually, sclerosis of the labyrinth is the cause, for which no treatment is of any account. However, as something must be prescribed, ten grains of iodide of potassium daily may be given for three weeks at a time.

Germany.

BERLIN, February 19th, 1905.

THE *Deutsch. med. Zeit.*, February 6th, contains a contribution by Dr. J. Lange on the

TREATMENT OF SCIATICA.

In twelve cases the following treatment was followed: At the point of exit of the nerve from the pelvis the skin was thoroughly disinfected and then, with a Schleich's syringe, a solution was injected into the nerve. This was to be lacerably simple, as it is a structure only $\frac{1}{4}$ cm. in width, and is always to be found in the same place. As the puncture through skin and

muscle was painless, the patient gave a prompt jump when the nerve in its sheath was touched by the needle. It was like an electric shock, and felt along the whole course of the nerve. This was looked upon as a sure sign that the nerve was touched. The pain was only momentary, as the solution followed immediately; 70 to 100 c.cm. were injected fairly rapidly. The puncture opening was then closed with sticking-plaster, and the patient was not allowed to lie on the side affected for some hours. Even during the injection the pain and tender pressure point disappeared, and after a time the patient complained only of a feeling of tension, which, however, passed off in the course of a few hours. The point of puncture remained painful a day or two. The solution employed was a 1 per cent. of β . eucaïne in an 8 per cent. solution of sodium chloride. Mild symptoms of intoxication had been observed, chiefly characterised by diminished appetite. In one case this lasted three days. Slight rise of temperature was also observed. The writer did not attribute any essential action to the eucaïne, but as it diminished the pain of the puncture it was as well to use it. He attributed the effect produced to compression and pulling on the nerve by the fluid, the action resembling that of nerve stretching. A cure was effected in six cases, in some, however, only after repeated injection. The effect was evident; one man, for example, who had suffered for four months and who could only limp along on crutches, was able to run forty-eight hours after injection. He recommended the method in obstinate cases.

At the Laryngological Society, Hr. Kutner spoke on the

INFLUENCE OF PREGNANCY ON TUBERCULOSIS OF THE LARYNX,

showing a case that was of interest, inasmuch as the patient was pregnant for a second time and the laryngeal disease was present during her first pregnancy also. She had then considerable difficulty in swallowing and hoarseness, which became less after the birth of the child. The left vocal cord was very red and had a cockscomb-like swelling in April last. Both cords were covered by a fold which gave one the impression of being the prolapsed mucous membrane of Morgagni's ventricle, the posterior wall of the larynx was infiltrated and ulcerated. In July she became pregnant again, and the condition got worse, so that the patient remarked that the hoarseness steadily increased. She was quite free from pain. In December she consulted the speaker. She was then voiceless, all parts of the larynx were infiltrated, and there was considerable dyspnoea. Then infiltration of the ary-epiglottic ligaments and cartilage and epiglottis came on. The general condition remained fairly good; there was no fever, no night-sweats, and only slight expectoration, grey in colour. There was not much lung mischief.

He looked upon the case as one showing the pernicious influence of pregnancy on the disease. The disease got worse visibly. On the other hand she showed exception to the rule that women generally succumbed to this disease after the birth of the child. As regarded treatment, there was the difficult question to decide whether abortion or premature labour should be induced. This decision depended on the state of the larynx and the stage of pregnancy. If the pregnancy was early and the changes in the larynx were not too far advanced, abortion should be induced.

In the discussion that took place, in which several members took part, doubts were raised as to whether interruption of the pregnancy would do any good. It must, however, be strongly emphasised that tuberculosis of the larynx, even if it had been cured, was a decided bar to marriage.

At the Society of Charité Physicians, Hr. von Leyden showed a case of

FRIGHT PARALYSIS

in a girl. æt. 16 , the disease taking on the type of a spinal paralysis. Psychological effects and long-lasting mental disturbances played a greater role in literature:

and in practice than in scientific medicine. Among the diseases which were attributed wholly or in part to psychical factors were chorea, Graves' disease, epilepsy, hysterical paralysis, paralysis of speech, and hemiplegias. The speaker mentioned several cases of fright paralysis from the time of the siege of Strasburg, which also corresponded to the spinal type of paralysis. Organic myelitis after psychic injuries had been observed by himself and Brieger. The real cause was not so much the first excitement as the subsequent recollection and brooding over it; one might assume a disposition to such diseases. The connection between jaundice, paralysis agitans, and psychical affections was of the same nature. In the case presented, sixty hours after the injury (fright from an attempt at house-breaking), there was paralysis of all the extremities and tactile and thermic anæsthesia and analgesia; the sensations of position and vibration were abolished. The prognosis was fairly good as the danger of organic disease was only slight. As regarded treatment, electricity and perhaps hypnotism were deserving of consideration.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, February 18th, 1906.

LACTIC SECRETION AND PREGNANCY.

At the Gesellschaft der Aerzte, Mandl gave his experiences in several cases of pregnancy to prove the practicability of Kreidl's experiments on animals. This subject has created a great deal of interest in the Society for some time past, and it was hoped that Kreidl's physiological demonstrations would have settled the question; but it seems that many are still sceptical of any good result that may follow. It should be remembered that a dispute arose about the function of separation of the placenta as the chief factor in stimulating the breasts to lactation; others contended that the death of the fœtus was the determining cause. Kreidl commenced operating on animals at different periods of pregnancy by performing laparotomy or destroying the fœtus *in utero*. In every case within two to four days after operation milk could be drawn from the breasts, from which he reasoned that the death of the fœtus was sufficient to stimulate the lactic glands. From this it was deduced that a practical diagnostic symptom had been discovered—that the presence of milk in the breasts during pregnancy was a definite assurance of the death of the fœtus. With these physiological facts before him Mandl now endeavoured to prove their utility by placing three cases before the members where the pregnancy was extra-uterine or tubal.

In the first case there was moderate hæmorrhage with intermittent colicky pains in the lower and left side of the abdomen; at the same time milk was emitted from the breasts. Laparotomy was performed and a typical form of tubal abortion was discovered.

In the second case, the hæmorrhage was not so great, but its constancy led to a dangerous state of the body. A microscopic examination was made of the secretion that could be drawn from the breasts, when the milk globules were found in great abundance. Laparotomy was performed, and a tubal mole was obtained, which he presented in a preserved form to the Society.

In the third case, the uterus was found to be enlarged on the left side, being soft and boggy in consistency. The patient suffered from cramps and pain in the lower part of the body, with intermittent hæmorrhagic discharges.

Milk could also be drawn from the breasts. From this he concluded that the case was a tubal abortion, and being so close to the uterus he adopted the expectant method of treatment. A few days later the lateral tumour suddenly disappeared, and ultimately became absorbed. The pregnancy in this case appears to have reached the tenth or twelfth week of duration. It would appear from these cases that the death of the embryo at an early period of pregnancy affects the milk secretion in the glands of the breast, which should not

be lost sight of as an important symptom in the diagnosis and treatment of the case.

Werth has set it down as a dogma that extra-uterine pregnancy should be operated on at once lest rupture of the membranes with hæmorrhage should take place; but it would seem that a dead embryo may disappear without any bad effects, and with an important symptom like the lacteal secretions, the attendant can confidently wait the recovery as was done in the second case. He does not consider the expulsion of the decidua from the uterus to be an uncertain proof of the death of the extra-uterine fœtus; but the milk secretion is a confirmatory diagnosis. The period that may elapse after the death of the fœtus varies according to different authorities, but two to four days are the recognised averages. Gessner records a case of tubal pregnancy in the third month which he operated on, and the milk did not appear in the breasts before the fifth day. He added that this proved to his mind that the death of the fœtus and not the placenta was the determining cause of the milk in the breasts. In the discussion that followed Halban denied that this was a new symptom, or that it could be recognised as diagnostic. Sinclair, Temesvary, and others had performed these experiments long ago, and recorded the same results. Observations in the human species had also been compared without arriving at any definite mode of operation. With Schauta's material at his disposal year after year, he had endeavoured to classify this abortive form of pregnancy, which he now divided into three. In the first form, the milk secretion appeared in the breasts on the first day; in the second form the milk secretion did not appear till after the discharge of the fœtus, even when weeks intervened between the death of the fœtus and its birth. The third form seemed to be evanescent, appearing shortly after the death of the fœtus, as a reactionary effect on the mamma, but a more definite effect was witnessed immediately after the birth of the fœtus. He was therefore inclined to adhere to the older view of the function of the placenta being the stimulating cause, and not the death of the fœtus only.

The Operating Theatres.

KING'S COLLEGE HOSPITAL.

POSTERIOR GASTRO-ENTEROSTOMY.—Mr. CARLESS operated on a male patient, æt. about 40, who for some months previously had been subject to pain coming on about an hour after taking food. This was followed by vomiting, but he had never shown any evidences of bleeding either in the vomit or the fæces. He complained of some tenderness, usually just to the left of the middle line, but occasionally more to the right, and always a little lower than the usual site of tenderness for a gastric ulcer. The stomach appeared to be slightly dilated, and the patient had lost weight. On palpation there was nothing in the shape of a lump to be felt, but there was some slight rigidity of the abdominal parietes. A test meal had been given, and the gastric juice showed a condition of hyperchlorhydria, with no lactic acid and no Oppler-Boas bacilli. Mr. Carless stated that in his opinion the case was one either of duodenal ulceration or of some contraction of the duodenum after ulceration. It was true, he said, that there had been no evident hæmorrhage, but it was quite possible to imagine duodenal ulceration without obvious hæmatemesis or melæna. Certainly the patient's general condition was rapidly deteriorating through the limitation of diet and the pain and vomiting associated with taking food, and it seemed quite clear that the reasonable practice to follow was to make an artificial communication between the stomach and the jejunum, whereby the

former organ might empty itself more rapidly without utilising the duodenum. He therefore proposed to do gastro-enterostomy, and, as was his invariable custom, to employ the posterior operation. An incision was made slightly to the left of the middle line, extending down to the umbilicus; the stomach and the upper part of the duodenum were found to be dilated, but there was no obvious evidence of ulceration, cicatrization, or new growth in spite of very thorough investigation both of the anterior and posterior surfaces. The omentum, and with it the transverse colon, were drawn up out of the abdomen so as to expose the under surface of the transverse meso-colon. An incision was then made through a non-vascular portion of this latter structure; through this opening the posterior wall of the stomach was protruded and the margins of the opening in the meso-colon were lightly stitched down to it. The upper part of the jejunum was next found and twisted over so that the surface which originally was anterior was made to look backwards, the result being, as Mr. Carless pointed out, that the same wave of peristalsis will carry the food out of the stomach and down the intestine practically in a continuous line. The jejunum was now clamped, and it and the stomach were approximated side by side by the hands of the house surgeon. A continuous catgut suture was introduced through the sero-muscular coats of the two organs for a distance of about two inches, and the free end was held by a pair of Spencer Wells' forceps whilst the further stages of the proceeding were carried out. An incision of a similar length was then made into the stomach and jejunum, running exactly parallel to this line of suture. A careful packing with gauze had been previously introduced beneath the approximated viscera so as to prevent soiling of the peritoneum, and a little bile-stained fluid, which escaped from the opening in the jejunum was mopped up with strips of gauze. The stomach had been carefully washed out with boric solution before the operation, and no fluid escaped from that organ. A second catgut suture was now employed to stitch the two layers of mucous membrane together; this, commencing on the left of the incisions, was carried continuously through the mucous membrane of the stomach and jejunum all the way round, the viscera being lifted up when the upper part of the incision was being dealt with. The loose end of the sero-muscular stitch was now picked up and the suture carried right round the junction, the stitches being introduced parallel to the margin of the wound according to the method described by Cushing, of Boston, as the right angle continuous suture; the apposition of the parts was so perfect that only one supporting stitch was required beyond the two main continuous sutures. The peritoneum was next cleansed, the parts returned, and the abdomen closed in the usual way. Mr. Carless commented on the gradual simplification of this operation, which had taken place during the last ten or fifteen years, and with it the decreasing mortality. As long as bone plates, bobbins, and buttons of different types and materials were employed the mortality, he said, was considerable; at the present time few surgeons employed any of these aids, but trusted simply to needle and thread, a deft pair of hands and suitable assistance; the last of these three, he thought, was all-important, as the assistant had much to do in suitably apposing the parts which were to be sutured together. The death-rate of gastro-

enterostomy was now, he remarked, something very small and the results of the posterior operation most satisfactory. Bilious vomiting was rarely troublesome, and the rapid emptying of the stomach was a most important element in the cure of many gastric and duodenal conditions.

It is satisfactory to state that this patient made a perfect recovery, and within a fortnight was eating fish, minced meat, and an ordinary diet without pain or discomfort and was only complaining of feeling hungry.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, FEBRUARY 22, 1905.

THE TYPHOID EPIDEMIC AT LINCOLN.

ONCE again the familiar history is repeated of the terrible nemesis that waits upon the district that tolerates an ill-guarded water supply. The city of Lincoln is now in the grip of an outbreak of enteric fever that has seized upon all ranks of her citizens with a suddenness that is both appalling and dramatic. Briefly stated, by the end of last week there had been some seven hundred cases of typhoid fever in Lincoln, due to contaminated drinking water. The action of the Corporation in the matter of the water supply has been one of criminal carelessness. For the past twenty-two years they have had solemn and repeated warnings on all hands as to the polluted and dangerous state of the water supply of the town. The city authorities took over the waterworks in 1871, and the first alarm appears to have been raised in 1883, when attention was publicly drawn to the fact that the River Witham, one of their chief feeders, was so polluted as to render fishing impossible. In the same year the Medical Officer of Health reported to the Council on the wholly unsatisfactory state of the water supply. His report spoke of “considerable pollution,” and declared that the water was “so contaminated as to be unfit for domestic purposes,” and concluded by saying that “water from such a source is dangerous.” The reply from

the sapient Lincoln Council was that upon inquiry they found the water did not afford reasonable ground for complaint. Two years later the Local Government Board took the matter up, and formally intimated that the Council would "incur a grave responsibility if disease should hereafter spread in the city." In the following year an Inspector of the same Board drew the attention of the local authorities to "the unsatisfactory state of the water supply." These warnings, however, were disregarded by the Council, and in the year 1887 we find the Local Government Board once again insisting upon "the unsafe character of part of the water supply." The reply to this last representation by the Waterworks Committee was to the effect that they had the question under consideration. It was still before the Committee when later in the year the War Office condemned the water supplied to the barracks as unfit to drink, and a little later an outbreak of enteric fever occurred at the County Lunatic Asylum. Presumably the continuous consideration of a matter so vital to the citizens of Lincoln as the purity of their drinking water proved too great a task to be sustained by the Special Committee. At any rate, in 1892 we find a report from that body recording the grotesque conclusion that, although the quality of the water was not good, it was nevertheless sufficient in quantity. No suggestion was made, however, as to improving the quality. In 1892 the Local Government Board appear to have made their last formal remonstrance to the City Council. In 1894 the water was unhesitatingly condemned by the York Medical Officer of Health. The next leading event in this instructive history is the wholesale outbreak of typhoid fever in Lincoln early in the year 1905. There can be no doubt that the apathy and neglect of the Lincoln city authorities are wholly responsible for the economic loss attached to this deadly epidemic, not to mention the suffering, the subsequent ill-health and the loss of life thereby entailed upon its sufferers. Without pretending to any exact legal knowledge upon the point, it is conceivable that each individual sufferer may be entitled to full monetary compensation from a controlling sanitary authority that has so wantonly neglected its primary duties in the face of many years of solemn and repeated warning. Even now the Council does not appear to be grappling with the situation so as forthwith to ensure a supply of pure water. They have adopted some method of chemical disinfection, but their distrust of its efficacy has been abundantly proved by a public notice to the effect that no water from the mains must be considered safe unless it has been boiled for ten minutes. Under the circumstances, the Lincoln folk are certainly placed in a most difficult and perilous position. The need of an immediately purified water supply is so imperative that we venture to bring to their notice the only scientific plan which we believe to be capable of meeting their requirements. For some time past an

apparatus has been used widely throughout France generally as well as specially by the French military authorities for the instant sterilisation of water. The "Salvator" apparatus, as it is called, can be applied on any scale, so as to provide for a cottage, or, if need be, for a large town. It sterilises the water absolutely by means of heat, is almost instantaneous in action, and delivers the outgoing water at practically the same temperature as that of the inflow. This method has proved a boon to many unhealthy stations and districts in France, and is well worth the serious attention of the Lincoln citizens in their present strait. Sympathy with the sufferers, however, must not allow our indignation to be diverted from the culpable negligence of the City Council. The whole history of Lincoln and its water supply reads like a chapter from some chronicle of mediæval and pre-scientific days. It reveals, moreover, something of completeness lacking in the policy and the power of the Local Government Board in dealing with recalcitrant authorities.

PHYSICAL AND MENTAL DEVELOPMENT OF SCHOOL CHILDREN.

THE Conference on School Hygiene organised by the Royal Sanitary Institute, to which passing reference was made last week, was a gathering of much significance. Its avowed object was to prepare those who are interested in the subject for participation in the International Congress to be held the year after next, and to stimulate study of the problems connected with school life and training. The Conference was, within the limits to which it was necessarily confined, thoroughly successful both in point of attendance and of interest displayed. It may not be too much to hope that the practical conclusions at which it arrived will reach the proper quarters, and that they will tend to strengthen the hands of those who are striving to inculcate ideas of what we may call the "larger education." A great many causes, chief among which we may put the influence and teaching of medical men, have been in operation of late years to lift education, so-called, out of the rut of dull routine, and to give it an aim and scope that our grandfathers, and even our fathers, never dreamed of. The one idea that education consisted in introducing so much "knowledge" into the brain of the child, much as a joke is put into the head of the proverbial Scotsman, has fortunately given way to a more scientific system of mental training; and of still more recent growth is that yet broader conception of education that looks to it to enlarge not only the calibre of the mind, but to develop the muscles and framework of the body. The best definition of that much-defined word "education" is that which describes it as the adequate adaptation of the subject for a future environment, and it should be recognised that no mind can develop independently of its physical counterpart, or, at any rate, that it is highly undesirable

that it should do so. A proper balance between the training of both elements is indispensable to success; indeed, there is no reason why the two should be regarded as in any way distinct. The larger education would make them mutually complementary—intimate and essential parts of a homogeneous whole. The Conference just held will do something—we hope much—to strengthen this new bond, and to nurture the tender plant of scientific pedagogy that is struggling to pierce the clods of ignorance and prejudice that cumber the ground. The view was generally expressed—and one would have thought it would be self-evident to every clear-minded man—that the mental training of children cannot be cast in any Procrustean mould, but that the general principles which direct that training must be carefully adapted to individual circumstances, so that the less favoured physically and mentally shall derive benefit and not injury from their school work. The necessary corollary to this proposition is that a person skilled in the diagnosis of mental and bodily defects should have, if not entire charge of, at any rate a preponderating influence in, the apportioning of suitable curricula. In other words, a medical man of experience and skill should be a vital and organic part of the school staff, and, as the result of his inspections and examinations, the individual child should be dealt with. If this principle be carried to its logical issue it seems to us that a far more extended influence will have to be conceded to the doctor than is at present contemplated by even the warmest supporters of the cause. An occasional brief visit will never enable a medical man, however perspicacious, to decide in those questions, for each child must become an object of individual study, and his peculiarities and idiosyncrasies be thoroughly appraised, before a just verdict can be given. Moreover, his progress must be anxiously watched, and he must be re-examined and overhauled at short intervals. Such duties and functions carry the question to a point still further than that now contended for. They could only be satisfactorily carried out by men of considerable leisure, aptitude, and inclination, and in towns of any size to regard them as side-shows in the work of the medical officer of health would be to assure that they could never be satisfactorily accomplished. The medical officer of education should be as much an expert in his own province as a medical officer of health is in his, as the duties would be not a whit less technical and many-sided. Physical exercises were naturally much dwelt on at the Conference, and certainly not more than their importance warrants. The form that these exercises should take is still the subject of a good deal of difference of opinion, but we think that the right note was struck by Mr. Legge, the Inspector of Reformatories, in pointing out that these should be essentially recreations, and not mere mechanical performances to be gone through as so much drudgery. Though the mind should not be taxed during the execution of bodily exercises, it should not be

bored, and an element of exhilaration will alone call out the full powers of the muscles. It is by virtue of this stimulus that English games, such as football and cricket, make for finer physique than the monotonous evolutions of the German gymnasia, though the latter are in themselves better conceived as agents for developing the muscles. In this connection we are interested to note that the suggestions made some time back in these columns that Jiu-Jitsu—the Japanese national exercise—is coming more and more into evidence in this country. It seems, on the whole, better to combine the features of a good general form of exercise than any other.

Notes on Current Topics.

Selling of Practices.

THE buying and selling of practices is an unsatisfactory business at the best of times. The vendor who has, through his own energy and skill, built up a practice, finds himself, when he wishes to retire, with only that intangible asset—goodwill—to dispose of; and even when selling in the best of good faith, he cannot insure that all or any of the patients who come to him for advice will continue to do so to his successor. The purchaser, too, enters into a compact whereby he parts with a sum of money on the chance that the patients will like him as much as they have his predecessor. And of this no guarantee can, in the nature of things, be forthcoming till he is thoroughly settled in the vendor's stead, when it is too late to recant if he finds a falling off in his returns. It is not to be wondered at, therefore, that it not infrequently happens that doctors succeeding others think that they have been let-in in buying a practice, and that the law courts are sought to settle the matter. Much interest has been taken in the West of England in a case wherein one medical man brought an action to recover damages for fraud in connection with a Devonshire practice which he bought, and which turned out very differently from what he had expected. The vendor, from his admissions under cross-examination, appears to have been of a restless disposition, for he had spent much of his life in going from place to place in England gathering together a small practice and selling it after a few years to a new man. In the place in respect of which the action was brought, he was said by the purchaser to have represented that his practice was bringing in £800 a year, and the purchaser paid him £1,000 for the goodwill. In the result he found that instead of £800 he only earned £185 a year, and he attributed the fees shown in the defendant's books to be due to unnecessary visits and excessive charges. The defendant had an X-ray apparatus which he was asserted to have used in all sorts of cases, from cancer to deafness, and it was contended that employment of these rays in something like one-fifth of all patients attended was unjustifiable. The case lasted a long time, and eventually the jury found for the plaintiff and awarded him £200 damages. The story as

told in court was a painful one, well calculated to bring shame to those who hold the reputation of their profession dear. Perhaps the most regrettable part of the case is the disrepute brought on the X-rays as a therapeutic agent; like all other scientific methods of treatment they have their limitations, and it is sad to see them be-lauded as a sort of panacea, when such praise, in the long run, can only bring about disappointment and contempt.

The Misfortunes of the Central Midwives Board.

THE position into which that unfortunate body, the Central Midwives Board, has allowed itself to drift, owing to its repeated recognition of unsuitable institutions and persons as training centres and teachers of midwifery, has been very clearly brought home to it by Sir William Sinclair. During a discussion on the recognition of teachers and training schools, Sir William Sinclair said that he declined to discuss in detail the applications before the Board because the Board had recognised such unsatisfactory applicants as teachers of midwifery, and had approved such unsuitable institutions as midwifery training schools that he did not see on what principle any applicant for recognition as a teacher, or any application from any institution to be approved as a training school, could now be objected to. He could only look forward to the Board continuing its present policy, so that an unanswerable case would soon be made out for reconstitution of the Board by an amendment of the Midwives Act, 1902. In answer, the Chairman admitted, "in defence of the unfortunate Central Midwives Board," that perhaps, in spite of much care and trouble, the Board had made some mistakes. This is an important admission, but we are inclined to suggest that the number of these mistakes would have been very much fewer if those members of the Board who possessed experience and knowledge of obstetrical matters had taken a firm stand, had insisted upon their position as members of the medical profession, and had voted as such instead of either following blindly a lay majority or else refusing to vote. We re-echo Sir William Sinclair's hope. *Quos Deus vult perdere prius dementat*, and to endeavour in such a case to effect a cure would be a waste of time.

Fraudulent Companies for the Practice of Dentistry.

THE Irish Branch of the British Dental Association have during the past week won an important victory in their crusade against bogus dental companies. The Branch applied through the intermediary of the Attorney-General for an injunction to restrain a company, who carried on business as Mr. Appleton, Surgeon-Dentist, Limited, from taking or using such a name, or from advertising for custom under it or any other name or style containing the word "dentist," either alone or in combination with any other word or words or any name or title, addition or descrip-

tion calculated to lead the public to believe that the business was carried on by a person registered under the Dental Act of 1878. They also applied to restrain the directors or any other member of the company from allowing the company to remain registered under its present name. The defendants entered no appearance, and the Master of the Rolls, before whom the case was heard, granted the injunction with costs. This judgment is of so far-reaching importance that we are compelled by considerations of space merely to state the facts in a brief form. In our issue of next week we shall discuss at length the bearings of the judgment on the difficult question of bogus medical and dental companies. It must not be forgotten that, although at present it is the dental branch of the profession that suffers most from this particular form of fraud, if bogus companies succeed in carrying through their fraud, bogus medical and surgical companies in large numbers will inevitably appear in a short time.

Syphilis in Physicians.

THE necessity of counting syphilis as an "occupational disease" of physicians has recently been urged by Blaschko, who has had as patients no less than twelve medical men suffering from the disease. The primary lesion occurred in nearly every case about the hands, and was received in the course of gynæcological examination or operation. In some of the cases the cause of infection was the accidental wounding of the finger with an instrument, but in most it occurred through some unnoticed scratch or minute lesion. In one case, indeed, infection was definitely traced to the performance of an autopsy in a syphilitic case. The primary lesion was usually very small, and by no means painful, and presented some difficulty in diagnosis; in particular it had to be distinguished from herpes, from anatomical tubercle, and from chancroid. Blaschko advises against excessive use of the scrubbing-brush in preparation for gynæcological examination, as he thinks it is responsible for many slight traumata about the fingers. He advises, too, and we cordially agree with him, the more frequent use of gloves in general gynæcological work.

Anthrax.

IT is disquieting to read from several widely-distant parts of the country that cases of anthrax are occurring from time to time. The Home Office rules for the protection of workers engaged in wool-sorting, washing, and combing have done much to lessen the risk attached to those occupations, but there are still loop-holes in the defensive armour, and while such is the case anthrax is bound to show itself from time to time. A case illustrating one of these defects was brought to notice at an inquest at Bradford recently. The deceased man was a wool warehouseman, and his duties consisted in packing "tops and nails" in sheets and bales, a part of the business that was not considered dangerous as the wool had

already undergone several processes of washing and drying before coming to the packers. The man, however, had a scratch on his wrist, and one day felt a pricking sensation in it; presently a pimple was noticed to form. Thinking, however, that his blood was merely "out of order," he did not place himself under medical treatment, and when he finally did so general blood infection had set in, and in spite of serum treatment he died in two days. We are glad to notice that the Home Office inspector who was present at the inquest was able to say that new rules were being prepared, and that Persian wool—the variety the deceased man was handling at the time of the accident—was to be severely hedged about with restrictions, but no rules can possibly be devised to protect workers completely without their active co-operation. One of the greatest difficulties in the administration of the Factory Acts is the carelessness and negligence of the workers with regard to their own welfare, and while this is so it is impossible to make sure that fatal accidents of the kind mentioned will not occur.

Longevity and Brain-work.

A GREAT deal of weight is attached to over-work and over-strain as a cause of early death, and there is constantly an increasing tendency to put down premature decease to these causes. It is doubtful, however, if mere over-work—that is to say, hard brain-work—is so widespread and potent a factor in causing early mortality as it is fashionable just now to make it. Over-strain, on the other hand, is another matter. A man of average constitution can persistently maintain a high level of intellectual toil for many years without damage, and even with benefit, if his home is free from cares and his surroundings moderately hygienic. The early breakdowns and premature deaths of many well-constituted men is due to burning the candle at both ends; a day of toil in the office or factory and a night of broken rest through ill-health or anxiety at home. We have only to look at the green old age which crowns the labours of most of our prominent politicians, whose lives are spent in a round of unremitting toil, to see that intellectual labour under severely trying conditions is quite compatible with excellent health and longevity. The converse, however, cannot be stated so emphatically. A medical witness in a recent High Court action expressed the opinion that "brain-softening" with early death was a very common occurrence in agricultural labourers, and that this was due to want of mental exercise. The intellect of the rural labourer "rusted out." Judges, he said, and others whose thinking capacities were greatly employed, invariably lived to an age far beyond that of the average rural labourer—provided, of course, they lived consistently. We are not surprised to read that the learned judge and his brethren of the Bar received this opinion with smiles of satisfaction, but, for our own part, while assuring them that there is no *prima facie* reason

why they should not last well into their second childhood, we cannot take so pessimistic a view of the prospects of the rural labourers. A sane mind in a healthy body is doubtless the ideal, but it is wonderful how well the animal functions can be performed in a body that owes but little to the control of the higher brain levels.

The Serum-Therapy of Tubercle.

DURING the past twelve months the method of serum treatment for tubercle most prominently before the profession has been that put forward by Marmorek. He held the view that tuberculin was not itself the toxin of tubercle, but that it was a bacterial product which served to excite tubercle bacilli to the production of a toxin. This being so, one could not expect any satisfactory result from treatment by anti-tuberculin serum. By the growth, however, of tubercle bacilli in a special medium, "leucotoxic serum," whose preparation is very complicated, he has been able to produce a toxin which causes definite lesions in horses and other animals. To this toxin an antitoxin is produced in the blood of horses. It will be remembered that when Marmorek published his investigations a year ago, they met with hostile criticism from many French observers. The later reports, however, both in England and Germany, have been more favourable. Latham, Richer, and Fry all think well of the action of the serum, and advise further trial. More recently Friedman has separated a culture of tubercle bacilli from the lung of a turtle, and this culture is so innocuous to higher animals as to be available as a vaccine. In addition, it causes so high a degree of immunity in the ox that the serum of the latter may be used as an anti-serum. No trials have yet been made in the human subject, but the prospects are most promising.

The Russian Giant.

MACHNOW, the Russian giant, who is now on exhibition in London, is a phenomenon that will have a special interest for medical men. It is claimed on his behalf—and with apparent justice—that he is the biggest man alive, and he is probably the tallest man of whom authentic record exists. Although only twenty-three years of age, his height in his socks is 9 feet 8 inches, and he is built in proportion to his altitude. Thus his hand is 1 foot 7 inches from finger tip to wrist, his foot is 2 feet long, his chest measurement is 60 inches, the circumference of his head 27 inches, and his weight 32 stone. To support this huge frame he eats an amount that rivals that of the fabulous contemporary of Jack-and-the-Bean-stalk. In four meals in the course of the day he gets through two dozen eggs, three to five pounds of meat, three or four loaves of bread, large quantities of potatoes and vegetables, three quarts of beer, and some three quarts of milk and tea. These quantities appear to be well attested, as do the measurements of his proportions, but the fact that arrests attention particularly in the accounts of the giant's habits is the enormous amount of

sleep that he needs. Normally he passes a large portion of the day in slumber, and he has been known to sleep for twenty-four hours on end. Even when awake his movements are slow and deliberate, and he is inclined to doze off when left alone, the only stimulus to exertion being the cravings of hunger, which are said to be very acute. It is impossible in the light of recent researches on giantism to regard this prodigious specimen of humanity as a mere "freak." He must be the subject of pathological change, probably in the pituitary body. The condition of general symmetrical giantism gradually developing is not on all fours with true Marie's malady, but it is closely allied to it. The prognosis with regard to longevity of the subject cannot be said to be a very bright one.

Clinical Examination of Saliva.

It is somewhat curious that of all the excretions the only one which we are in the habit of examining systematically is the urine. This is doubtless due to the ease with which we can obtain it, and the large quantity which is excreted. It is of interest, however, to ask in how far the changes from the normal undergone by urine are parallel to those that take place in the other excretions. Dr. Lederer, of New York, has examined the saliva in a number of pathological conditions, and his observations have been published. (a) Recognising the difficulty of obtaining saliva as it flows from one of the glands, he has contented himself with the mixed fluid as found in the mouth. He examined a large number of cases of diabetes, and in 85 out of 158 glucose was found to be present. Dr. Lederer is of opinion, too, that in more than half the cases of diabetes there was a diminution of the amount of saliva secreted; this is obviously, however, a difficult matter to test with anything like accuracy, as the rate of secretion of saliva is so easily altered. In 90 per cent. of the cases there was no alteration in the amylolytic action of the saliva. In a number of cases of "uricacidæmia," uric acid was found excreted by the saliva. Bile pigment was looked for on several occasions, but only discovered once. According to Lederer's observations acidity of the saliva is by no means uncommon, as he found it in many different conditions—diabetes, acute gastritis, hyperchlorhydria, and pyloric stenosis.

Euphagia.

THE dreadful consequences that may ensue when insufficient time is given to the process to mastication are familiar to every first year's student of medicine. Lecturers in physiology always take care to impress upon their hearers the importance of the first digestive process, that of insalivation, which should on no account be hurried over. Due preparation cannot, of course, be given to the food in the mouth when "the grinders are few," and every physician has met with severe and chronic forms of dyspepsia which have been completely cured by a visit to

the dentist, who has fitted a suitable set of false teeth. Even if the dentition be perfect, the food may be bolted, or the surroundings unfavourable to the proper and leisurely consumption of a meal. This ideal process is termed "euphagia" by Professor Max Einhorn, (a) who is a strong believer in the influence of the mental state upon digestion, the importance of which has also been shown by Pawlow. Cheerful company, appropriate music, and pleasant conversation go a long way towards the enjoyability of a meal, and there is a physiological reason why this should be so. It is commonly said that those who eat quickly are quick in everything else, but the converse is certainly not the case. The habit of eating too slowly, known as bradyphagia, is more rarely seen, but it occasionally occurs to such an extent as to constitute a veritable morbid state. Particles of food are vigorously masticated and re-masticated until it would seem that the individual is actually afraid to swallow. The condition which has been described as sitophobia may ensue in some cases. Neurasthenics are particularly liable to err in this direction, and such should be made to finish their meals at the same time as others, provided, of course, that there is no physical impediment to their doing so.

Instruction in Domestic Hygiene.

THE starting-point of hygiene, like that of charity, should be at home. If the principles of healthy living are to take root in the heart of the nation they must first be taught by the fire-side and in the kitchen. Educational authorities are, happily, beginning to realise what an immense influence they can exert in this direction upon the minds of the young. The observance of the laws of health does not come naturally any more than does the love of books, and, indeed, men are apt to be afraid of both, unless they have been accustomed to them from their infancy. It is a wise and prudent step, therefore, to sow early the seeds of the knowledge of hygiene, and especially to display it in an interesting and a practical fashion. The provision of an ideal schoolroom from the sanitary point of view is one thing, and the visual demonstration of the poisonous properties of carbonic acid, simply illustrated so as to be readily grasped by the mind of every scholar, is quite another. That some useful work is already being done by the London County Council in this direction is shown by the interesting exhibition of work done by the scholars of the Public Elementary and Evening Continuation Schools in the Boroughs of Bethnal Green and Stepney now on view at the Whitechapel Art Gallery. Comfortable cradles are shown simply made out of ordinary clothes-baskets, and if these are not obtainable, the elder girls are taught how to make hammock beds out of sacking and rope. The teaching of housewifery, thus imparted, cannot fail to be of the greatest benefit to the inhabitants of the crowded districts in the East

(a) *Journ. of the Amer. Med. Assoc.*, December 10th, 1904.

(a) *Medical Record*, January 7th, 1905.

End of London, and we note also that considerable stress is laid upon the feeding and general management of infants, cards of instruction being issued upon this most important subject.

Copper as a Disinfectant.

SOME of the American dailies have been devoting much attention to the use of copper sulphate for the destruction of typhoid bacilli. It is claimed that by simply adding small quantities of sulphate of copper to a polluted drinking water, the bacilli are speedily killed, and all danger from the water is at an end. As a matter of fact, the basis for such extravagant statements is a series of laboratory experiments undertaken by Dr. Edward Martin, the Director of Public Health in Philadelphia. He finds that a very slight trace of copper in water is sufficient in a few hours to destroy any typhoid bacteria that may be present. For instance, if water containing typhoid bacilli be allowed to remain in a copper vessel for three hours, it is said that enough copper will have been taken up to render the water sterile. It is, of course, much too early in the course of Dr. Martin's investigations to come to any conclusions as to the possibility of making use of this property of copper on a large scale, though he at present thinks the prospect hopeful. In the meantime the question is raised as to whether copper is itself a safe constituent of drinking water. For long it has been held that there is grave danger in the use of copper utensils for cooking and such purposes, but we confess that the evidence in favour of this tradition is but slight. It is improbable that the small quantity of copper required, according to Dr. Martin, for the destruction of typhoid bacilli would have any injurious effect on the human organism.

An Historic Autopsy.

To a recent number of *American Medicine* Dr. Andrew Smith, of New York, contributes an interesting account of the *post-mortem* examination made by him nearly a quarter of a century ago on the body of President Garfield. Garfield had been shot in the abdomen early in July, 1881, but did not die till September 20th, having shown during the intervening months symptoms of pyæmia. The surgeons, by examination of the wound with a flexible probe, had formed the opinion that the bullet was lodged in the right iliac fossa, and this conclusion had been confirmed by Dr. Graham Bell's ingenious "induction balance." Accordingly, when the autopsy was begun it was agreed to remove the hollow viscera before beginning the search for the ball. To everyone's surprise, no fistulous path was to be found in the iliac fossa, and it was only after prolonged search in that region that it was noticed that several of the vertebræ were covered with a dense exudate. On removal of this it was found that the bullet had entirely pierced the first lumbar vertebræ, passing obliquely from right to left. It was finally found encysted close to the tail of the pancreas, and it had been removed and thrown aside with the viscera. In its passage

it had carried splinters of bone in its path, and had set up a line of abscesses. In addition, it had grazed the splenic artery, causing an aneurysm, the rupture of which was the immediate cause of death. Dr. Smith does not think that, even with the use of the X-rays and modern methods of treatment, any other result than death could have followed the wound received by President Garfield.

PERSONAL

SIR FRANCIS LAKING and Sir Frederick Treves last week received Queen Alexandra, attended by Lady Suffolk and the Hon. Charlotte Knollys, who paid an informal visit to the Royal College of Surgeons, Lincoln's Inn Fields.

MR. EDGAR SCHUSTER, of New College, Oxford, has been appointed to the Francis Galton Research Fellowship in national eugenics.

THE Charter Day dinner of the Royal College of Surgeons, Ireland, which was to have taken place on Saturday evening, February 11th, was postponed owing to the illness of his Excellency the Lord Lieutenant, who had accepted an invitation to be present. The new date has been fixed for the 25th inst. We understand that the annual dinner of the Leinster Branch of the British Medical Association, which was to have taken place on that date, has consequently been unavoidably postponed.

THE following have been elected members of the Board of Faculty of Medicine, Oxford, and will hold office until February, 1907: Sir William Selby Church, Bart., M.D., Christ Church, Honorary Fellow of University College; Walter Ramsden, D.M., Fellow of Pembroke College; Ernest William Ainley Walker, D.M., Fellow of University College; Walter William Fisher, M.A., Corpus Christi College; Samuel Hatch West, D.M., Christ Church; William Bruce Clarke, B.M., Pembroke College.

THE annual meeting of the Leinster Branch of the British Medical Association will be held in the Royal College of Physicians, Dublin, on February 25th, when the incoming President, Sir Thomas Myles, will deliver an address.

MR. W. H. CURTIN, local sanitary inspector at Lincoln, has fallen a victim to typhoid fever. He worked heroically but unsuccessfully to stamp out the epidemic before it gained a hold.

THREE candidates have been selected for the Clerkship of St. Bartholomew's Hospital: Mr. A. J. Austin, secretary of the City of London School; Mr. T. Hayes, secretary of the East London Hospital for Children at Shadwell; and Mr. J. M. de Vine, secretary of the National Hospital for Consumption, Ventnor. The governors of the hospital will elect one of these at their Court Meeting on the 23rd inst.

THE Council of the University of Leeds have appointed Dr. J. Spottiswoode Cameron (the City Medical Officer of Health) as Professor in Public Health, and Dr. Porter (his assistant) as honorary demonstrator in the same subject, in the School of Medicine. At the same time Dr. Trevelyan was appointed Lecturer in *Materia Medica* and *Pharmacology*.

MR. MALCOLM MORRIS will deliver the Harveian Lecture on "Some Modern Therapeutic Methods in Dermatology; with Exhibition of Cases Treated by the X- and Finsen-rays," on March 9th, at 8.30 p.m., at the Stafford Rooms, Titchborne Street, Edgware Road, London.

PROFESSOR SYMINGTON, of Queen's College, Belfast, has been appointed an Examiner in Anatomy in Trinity

College, Dublin. Professor O'Sullivan and Dr. Henry Jellett have been re-appointed respectively Examiners in Pathology and in Obstetrics and Gynæcology in the Royal University of Ireland.

DR. A. R. CUSHNEY, of the University of Michigan, has been appointed to the chair of Pharmacology at University College, London.

THE council at University College Hospital, London, have passed resolutions of regret on the resignation of Professors F. T. Roberts and Vernon Harcourt.

THE ASSOCIATION OF MEDICAL DIPLOMATES OF SCOTLAND—INAUGURAL DINNER,

FEBRUARY 14th, 1905.

LAST Tuesday some fifty-eight guests, representative of the above Society, gathered at the Trocadero for their inaugural dinner. Mr. Claude St. Aubyn Farrer, L.R.C.P.&S.Ed., President, occupied the chair. Among those present were Sir J. Andrew Clarke, Sir John Tyler, Colonel Anderson, I.M.S., Brigade Surgeon Lieut.-Colonel E. J. Hunter, Drs. Fitzgerald Powell, Skene Keith, Lewis (St. Leonards), Outterson Wood, Parsons, C. O. Hawthorne, James Rutherford (Harrogate), Euphemia Stoker, F. J. Waldo, Messrs. Heather Bigg, Noble Smith, Milson Rees, Chisholm Williams, Richard Greene (Lewes), S. Lightfoot (Watford), F. E. Fenton, and others; Dr. David Walsh (Hon. Sec.) and Mr. William Bell (Hon. Treasurer).

The President, in his speech, explained that there was a large and increasing number of Scotch diplomates practising in England, Ireland and Wales out of touch with their own colleges and with one another, and the present Association was created to advance the interests of Scotch diplomates in every way; to let them air their grievances, one of which—having gone on for 300 years without a distinctive licentiate gown—was already remedied, for at that moment he and Dr. David Walsh (Hon. Sec.), and Dr. Euphemia Stoker, the first lady to join their Association, were wearing the very gowns asked for. There had been difficulties at the beginning, but members were rapidly joining. When he had gone up to Edinburgh, men like Sir Patrick Heron Watson and Sir John Halliday Croom and Sir Alfred Cooper had readily consented to become Vice-Presidents of the new Association. It was clear that any single individual, however strong and energetic, could do little or nothing by himself; but, an association got together, great things were possible. At future meetings consultants and specialists would meet general practitioners, and mutual good would undoubtedly ensue. He had no idea until the Association was formed that Scotch diplomates had so many grievances; but the Council were glad to have an opportunity of knowing them, and had determined to try and remedy the greatest of all, namely, their present position with regard to London hospitals. Moreover, for the convenience of members, districts would be grouped, so that each member would know if any of the Association lived near him.

Dr. David Walsh (Hon. Sec.), replying for the Association, referred to the great debt of the Association to their former hon. secretary, Mr. Heather Bigg. He remarked on the fact that they were having their inaugural dinner early in the year of the tercentenary of the Royal College of Surgeons, Edinburgh. That coincidence he could not but regard as an omen of the happiest augury. He hoped with the President that the objects for which the Association had been formed would be carried out, especially that of bringing medical men living in one district in touch with one another. In that way the Association of Scotch Diplomates might be laying the foundation of a real and universal organisation in the ranks of the medical profession. Only the other day he had had a letter from one of their Council asking whether there was in Croydon any member of the Association to whom he could send a patient. One other reform demanded by

many diplomates was the substitution of "Member" for the title of "Licentiate" of the Royal Colleges of Surgeons and Physicians. In this he echoed the opinion of all Licentiates, although they were faced with the initial difficulty with regard to the formal title of "Doctor," that a Licentiate did not hold a degree but he thought some compromise would probably be arrived at. Their position with regard to the well-nigh universal exclusion from London hospitals was extraordinary when one reflected on the number of men with Scotch qualifications whose work was even to-day benefiting hospital patients in London, and, indeed, so far as that went, all over the world. Who did not remember the late Dr. McLagan and the world-wide boon he conferred upon humanity by the introduction of salicylates in the treatment of rheumatism; Donald Ross and his researches into tropical disease; Simpson and chloroform; Lister and aseptic surgery? yet the men coming from schools that could boast such names were excluded from the majority of honorary hospital appointments in London, and from a smaller number in the provinces. Such unfair regulations he hoped and believed could not exist much longer if their Association and its indefatigable President did all the work they anticipated.

Mr. Noble Smith proposed "The Army, Navy, and Volunteers," in a brief but pointed speech.

Sir J. Andrew Clarke, replying for the Army, said there was one point in the Army Medical Corps he would like to notice—that in times of war outside medical civilian help had to be sought in spite of the efficient help rendered by the Red Cross Brigade. He would have the Army Corps organised in times of peace so effectually that when war came everything of the medical service would be strong enough for the demands put upon it.

Colonel Anderson, I.M.S., and Brigade Surgeon Lieut.-Colonel Hunter, V.M.B., also responded.

Dr. Hawthorne proposed "The Council and Officers of the Association."

Mr. Sidney Stephenson, in response, said they were an Association with many objects. Nothing that was popular among the members would be uncatered for by the Council, and he hoped the disabilities under which Licentiates had hitherto worked in England would speedily be rectified. Dr. St. Aubyn Farrer was an indefatigable President, and had given up the whole of his spare time to promoting the interests of the Association.

Dr. Euphemia Stoker (who wore the handsome new gown of the R.C.S. of Edinburgh) replied on behalf of the lady members of the Association, who were six in number. The lady doctors had all felt honoured by being admitted members of the Association, and she hoped to see them one day on the Council.

Dr. Fitzgerald Powell proposed the toast of the visitors, which was responded to by Dr. Snape, Dr. F. J. Waldo and others.

Some excellent songs were given by Miss Eugénie Neilson, Miss Amy Brook, Mr. Frank Moody, and Mr. Margetson.

[Society of Apothecaries of London.

Surgery.—H. H. R. Bayley (Section II.), A. Beeley (Section I.), J. A. Davies (Section I.), L. Sells (Section I.), R. W. Taylor (Sections I. and II.), I. C. Thorburn (Section I.), P. L. Vawdrey (Section I.).

Medicine.—A. Beeley (Sections I. and II.), J. B. Bradley (Section II.).

Forensic Medicine.—A. Beeley, H. A. Browning, C. F. Kernot, P. C. W. Laws, W. A. T. Lloyd, J. A. R. Wells.

Midwifery.—A. Beeley, A. J. K. Brayton, O. P. N. Pearn, I. C. Thorburn, J. H. Wolfe.

The Diploma of the Society has been granted to the following candidates, entitling them to practise Medicine, Surgery, and Midwifery:—H. H. R. Bayley, R. W. Taylor, and J. H. Wolfe.

Special Articles.

SURGEON-GENERAL EVATT'S REPORT ON THE

IRISH MEDICAL ASSOCIATION.

As Special Commissioner on behalf of the *British Medical Journal*, Surgeon-General Evatt, C.B., early in 1904 crowned a visit to Ireland with a report on its Poor-law medical service, which classed him at once as a powerful and imaginative writer. A suggestion contained in that report was that the medical profession required better organisation than then obtained, and so, in order to carry this into effect, arrangements were made last autumn between Surgeon-General Evatt and the Irish Medical Association by which he was to report on a scheme for reorganisation of the Association, and to indicate whether any changes were desirable in the much-discussed Mayo-Enniskillen resolution. It is possible that such a report as this might well have been written by the General in the quiet of his study without again going over the ground that he had already covered in Ireland, and without depriving the badly paid Poor-law medical officers of the several hundreds of pounds which they so readily subscribed for his payment. However, he decided to visit Ireland. He was brought over to speak to an Inaugural Address in St. Vincent's Hospital before any arrangements had been made for his reception in the provinces; several places such as Waterford, Limerick, and Sligo did receive him, but, particularly in the North, the time for such an invasion was considered inopportune and the services of the General were dispensed with.

During his campaign in the West, reports of various kinds were set in circulation concerning him. One of them credited him with using his platform to promulgate Home Rule doctrines, another gave him credit for denouncing the incapacity of the Dublin teachers of medicine and surgery and the inefficiency of the medical schools.

The appearance of his report was therefore looked forward to with interest, and also, perhaps, with some misgivings. When in due course it reached the secretary of the Irish Medical Association, copies marked "Confidential" were sent to every member of the Council, and its consideration was fixed for Wednesday, 15th inst. We understand that at this meeting the report was referred to a sub-committee on the understanding that it should not be divulged to the Press until the Council had again met to consider the recommendations of the sub-committee in regard to its adoption and publication. On the following morning, however, the Editor of one of the Dublin daily papers announced that a correspondent had favoured him with a copy of the report, and a few carefully selected and spicy extracts were given in which the writer had passed serious strictures on the two Irish Colleges of Physicians and Surgeons. These two bodies are accused of having treated their Licentiatees with neglect and want of sympathy, and at their doors Surgeon-General Evatt places the blame for the condition into which the Irish profession of medicine has been allowed to fall. Perhaps if the I.M.A. were again to employ Surgeon-General Evatt, he will first ascertain what proportion of the medical practitioners in Ireland hold their qualifications from the Irish Colleges. Supposing he then finds that this amounts to even one-third of the total number, will he annihilate with his pen the two universities and the Scotch bodies who are responsible for manufacturing the remaining two-thirds because these bodies do not provide clubs and afternoon tea for their graduates? It is highly probable that the Colleges may have to take action to defend their reputation from charges which are not only libellous, but misleading and without foundation. Surgeon-General Evatt says: "If ignorance and drunkenness are to-day doing a distinct damage to Irish medicine, the eternal blame for them will rest on the cliques that figure before the

world as the Royal College of Surgeons and Royal College of Physicians in Ireland." Wild talk of this kind can only injure the I.M.A., and that to a very vital degree. The College of Surgeons has housed the Association for many years, and it is almost past belief that a gentleman, who presumably must be a member of the Council of the I.M.A., and who has been enjoying the hospitality of the College, should hand over to the Press a confidential document which contains untrue and libellous statements regarding that College.

Surgeon-General Evatt's remarks concerning the Dublin consultants who accept titular honours while their dispensary brothers are perishing in the country are so singularly wanting in taste, and have so little to do with the reorganisation of the I.M.A., that their introduction can only lead to estrangement and mischief in the profession. Only a dreamer of the most irrational dreams could state, as is now stated by Surgeon-General Evatt that "the I.M.A. ought and must become an important national faculty of Medicine to be the controlling force over the medical profession in Ireland." Surgeon-General Evatt, who is a Licentiate of the Royal College of Surgeons, did not at any time think it necessary to present himself for the Fellowship Examination of this College, although this is just what a good proportion of the Licentiatees of the College do. It is one of the means by which their scientific efficiency is maintained. To obtain the Fellowship requires from them money, time, and study; and if there are Licentiatees of the College like Surgeon-General Evatt himself who are content to ignore, or unwilling through laziness to seek for, higher qualification within their reach surely the College is not to be blamed in the matter. Surgeon-General Evatt is dissatisfied with the mode of election by co-option to the Fellowship of the Royal College of Physicians. It is the same method by which Fellows are elected in the London and Edinburgh Colleges of Physicians. In the case all three Colleges there is a membership examination, which takes the place of the Fellowship Examination in College of Surgeons, and it will probably be some time before the Charter of the College of Physicians is so altered that a man may be admitted to its Fellowship without any regard to his professional attainments and worth other than those disclosed by examination. He is pleased to refer to the Fellows of the College of Physicians as a narrow, bigoted clique. Bigotry is an unpleasant and an ambiguous term. Will Surgeon-General Evatt particularise? Finally, we regret that this unwarrantable attack should have been made on the Irish Colleges by an Irishman, and that another Irishman should have been found capable of handing over a confidential document to the public Press, by which only a few extracts most injurious to the interests of the I.M.A. were printed and to the discussion of which we have been compelled to confine our remarks. Doubtless much that is good will be found in the remainder of this report, and many suggestions that may help to restore the prestige of the Irish Medical Association. It is unfortunate that the gentleman who violated the confidential character of the report only did so to an extent that is calculated to injure the Association, and that he did not also publish that part which deals with its present constitution. It is equally unfortunate that Surgeon-General Evatt has apparently exceeded his instructions.

If he had been content to carry out whatever loosely expressed instructions he received in regard to a suggested scheme for the reorganisation of the Association, subscribers might have felt that they had received some value for their money, but now we fear that the outcome of the whole conception must be material injury to the Irish Medical Association.

CYSTIC ENDOMETRITIS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In the interesting communication by my friend, Dr. Purefoy, in your last issue, the following occurs:—

"In cystic, as in every other form of endometritis, the first and perhaps the most important indication to be fulfilled in treatment is to secure a sufficiently patulous condition of the cervical canal to admit of free escape of healthy and unhealthy discharges."

Dr. Purefoy does not tell us how this is to be carried out. My own plan for years past has been to introduce my hollow spiral wire stem open from end to end to be worn after curetting, especially so as to ensure a patulous canal for sufficient time to effect a cure. The mere dilatation and curetting I have found long since quite inefficient, and have been amused at the efforts made to drain the uterus by iodoform gauze (or, indeed any kind of gauze). How any viscid discharge can possibly find its way through gauze I fail to see? the gauze acting more often as a plug than a drain, obstructing instead of aiding the exit of secretions. Ordinary cases of endometritis can be cured by *free drainage alone*, if the drainage-tube be worn long enough, which, of course, will depend on the severity of the complaint and the judgment of the gynaecologist. Dr. Purefoy has kindly alluded to my uterine applicator and curette combined, which will, I imagine, if used supply the want he alludes to, *viz.*, a safe applicator.

I am, Sir, yours truly,

ALEXANDER DUKE.

THE CLASSICAL SYSTEM IN OUR PUBLIC SCHOOLS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—It would be well if some of us took an interest in the question of what we think our boys should be taught at school, when we look forward to their lives being spent in the practice of our profession. Many years ago—that is, in our fathers' and grandfathers' times—the public schools were regarded as confined to the education of boys intended for one of the professions—the church, the law, or medicine. Our universities were the same, except that some young men of wealth or rank, who were never going to work for a living, went up to them, so that they might enter into political life with certain knowledge and tastes that the best of the aristocracy of this country consider necessary for the upholding of the character of a great family. The Church naturally looked to the study of the Classics and the religious literature of the past as the best preparation for those that were going to be the teachers of religion. The lawyers, too, were obliged to know something of the Latin tongue, as the whole system of our laws is based on Roman legislature. As for the doctors, there was a feeling that in the writings of the Greek and Roman authors were to be found the best types of careful and accurate observation of the symptoms, treatment, and characters of disease.

The ancients had handed on to us a reverence for the profession based on the spirit in which it was followed, and the years of study expected to be devoted to it.

Things have changed during the past fifty years. The College of Physicians gave up its Harveian Oration being in Latin; and now our prescriptions may be written in the vulgar tongue. There are only a few left now who hold the views of their grandfathers on this question of education, and the leaders of them are headmasters of some of our great public schools. They have not been pleased to see the changes and have opposed those introductions of the teaching of science which now in some of our schools and universities takes precedence of the Classics.

Of course, one of the chief obstacles to this teaching of science was removed when headmasterships were

not confined to the Church. The idea that we were wise in trusting our boys to men of religion was natural, but we have gradually learnt that true religion is to be found among the leaders of science in this and other countries in as high, if not more unselfish and admirable a spirit, as among the professors of religion.

The members of the medical profession have been naturally inclined to the study of science, and the dogmas and creeds of religion have not found great support among them. To come to the simple question what kind of education is the best to make a boy a good doctor, it should be carefully considered by all those who have sons preparing for the profession. If a boy grows up, and finds that his father has foolishly entrusted to the schoolmaster a matter that he ought himself to have directed and controlled, and that the mistakes made in the very important work of training have brought troubles later in life which could easily have been avoided, those feelings of respect which should exist between parents and children must be disturbed, and instead of reverence and esteem, little but contempt can fairly be expected to remain. A boy brought up with the idea that he cannot be a gentleman unless classically educated, and that the money spent on a public school and university is capital invested in the safest way to secure him provision in professional life, will be sadly disappointed. If left without means, and possibly expected by his parents to support himself when his training has ended, he may find that he is thrown out into the world, and is really worse off than the son of a poor working man; for he is like a thoroughbred horse being put to the plough. What mistakes parents may make are well seen in our Colonies, for there is nothing left for some but to disappear from the old country and begin anew. Let us not be misled now by such men as Dr. Warre and others in the education of boys for the medical profession. There is a great deal still to be done to make the present system satisfactory, for the cramming for examinations is bad; and there is a tendency among the boys to avoid the steady practical work which they look down upon with a kind of contempt as beneath them and unworthy of attention.

I am, Sir, yours truly,

R. L.

Obituary.

DR. CHARLES HERBERT GAGE-BROWN, M.D.

DR. CHARLES HERBERT GAGE-BROWN, M.D., died at Cadogan Place, S.W., on Tuesday last from pneumonia, after only a few days' illness, at the early age of 45. He was the eldest son of Sir Charles Gage-Brown, K.C.M.G., was professionally educated at the University of Edinburgh, and at the medical school of Middlesex Hospital, and had held the appointment of clinical assistant at the Central London Throat and Ear Hospital, in the electro-therapeutic department of St. Mary's Hospital, at the Hospital for Children in Great Ormond Street, and at St. Luke's Hospital.

FLEET-SURGEON DONALD MACIVER, M.D.

WE regret to record the death of Fleet-Surgeon Donald MacIver, M.D., R.N., retired, who died at Arundel Gardens, W., on February 8th, aged 66. Educated at Edinburgh University, where he took his M.D. degree in 1861, and at St. Bartholomew's Hospital, he entered the Navy as a surgeon in 1863. Promoted to the rank of staff-surgeon in 1877, he retired in 1884 with the rank of fleet-surgeon. In 1867-68, when in the Canadian insurrection, and serving in H.M.S. *Wizard*, Dr. MacIver was ever at the call of the wounded and suffering, either Turk, Egyptian, or Cretan. These services contributed largely in maintaining peaceful relations with both belligerents. Dr. MacIver also rendered valuable services in China and elsewhere.

NATHANIEL DAVIDSON, L.R.C.S. EDIN., L.S.A.

MR. NATHANIEL DAVIDSON was born in 1805 and would have completed his century in March. Educated

at Edinburgh, he took the licence of the Edinburgh College of Surgeons in 1828, and obtained the licence of the Apothecaries' Society of London in 1829, practising for many years in George Street, Portman Square. In 1861 he obtained the licence of the Royal College of Physicians, which at that time conferred the brevet rank of "doctor," and retired about twenty-five years ago.

JAMES ALEX. INNES, M.D., C.M.ABERD.

DR. INNES, for forty years medical practitioner in Dufftown, has just died after a short illness. Deceased was born at Keithmore, Auchindoun, in 1839, and received his early education under the late Mr. John Macpherson, parochial teacher, who also taught Lord Mount Stephen, the late General Sir Donald Stewart, and other eminent men. He had a distinguished college career, graduating in medicine in 1864. He had a large local practice, and still larger consulting practice. In 1882, in appreciation of his services, a sum of £340 was collected, as a testimonial, but on his being acquainted with the fact he asked that the money be returned to the subscribers, his plea being that many gave who could ill spare it. Deceased was in his sixty-seventh year, and practised up to a few weeks previous to his death.

CAPTAIN EDWARD JOHN DOBBIN, R.A.M.C., M.R.C.S.ENG., L.R.C.P.

THIS officer, who joined the department last July, died suddenly at Tunbridge Wells at the early age of thirty-three. By his death a career of brilliant promise has been brought to a premature close. He was educated at Middlesex Hospital, and took the conjoint English diploma in 1895. In 1893 he was appointed Prosecutor of the English R.C.S., and won the Lyell Gold Medal at Middlesex Hospital in 1894, besides gaining many other distinctions.

ALFRED VAVASOUR GRIFFITHS, M.R.C.S., L.S.A.

THE place of Mr. Alfred Vavasour Griffiths as a doctor and friend will not be easily filled. He died at the age of fifty-six, from pneumonia following influenza. After receiving his medical education at Queen's College, Birmingham, Mr. Griffiths took the diploma of M.R.C.S. in 1872 and that of L.S.A. in 1873. He for many years filled a large and important place in the town life of Fenton. In his public capacity he was medical officer of health for Fenton and held many other appointments.

MAURICE LING, M.R.C.S.ENG., M.D.DUR.

IT is with much regret we note the death on February 1st of Mr. M. Ling from appendicitis at the early age of forty-five. Dr. Ling, who was educated at the London Hospital, qualified as L.S.A. in 1877, M.R.C.S.Eng. in 1878, and took the degree of M.D. Durham in 1900. He was in practice for some years at his home in Suffolk, and came to London in 1894, where he practised first in West Halkin Street and subsequently in Harley Street. A man of wide experience, even in the short time that he followed his profession in London, he obtained support from several eminent physicians and surgeons. He was known to have a practical and thorough knowledge of his profession, and was genial and courteous to all with whom he came in contact. An accomplished and exceptionally well-read and resourceful practitioner, his death will be deeply regretted by all.

GEOFFREY HETT, M.D.FDIN.

DR. GEOFFREY HETT, who died recently in his sixty-first year, was trained at King's College Hospital, where he was a prizeman in anatomy. He afterwards studied at Edinburgh University, where he graduated M.D. in 1871. Previously to settling in practice, Dr. Hett travelled, and acted as house-surgeon to the Lincoln County Hospital, and after at Weston-super-Mare. Thirty years ago he was elected to the staff of the Westbourne Provident Dispensary, giving to that

institution unstinted service. Dr. Hett enjoyed long walks, and celebrated his fiftieth birthday by walking to Brighton from London. He was for many years a member of the Harveian Society and London Lincolnshire Society. He leaves a widow, one daughter, and three sons.

RUSSIA has sustained the loss of two eminent surgeons in the persons of Dr. Alexander Broboff, professor of surgery in the University of Moscow, who was the author of various surgical works, and Professor Nicolas Sklifosovski, surgeon to the Military Medical Academy in St. Petersburg, President of the Organising Committee of the International Congress of Medicine at Moscow.

Literature.

AFTER-TREATMENT OF OPERATIONS (a)

WE must congratulate Mr. Lockhart Mummery on the success of his book. The fact that the first edition was sold out in less than a year of its publication shows that it has filled the vacancy in surgical literature for which it was designed.

In the introductory chapter a section has been added on smoking and drug habits in their relation to operative procedures, and the description of post-operative insanity has been enlarged.

When reviewing the first edition we drew attention to the excellence of the chapters on abdominal surgery; these have now been enlarged, especially the part dealing with the operation for appendicitis, their value is therefore increased. We also praised the chapter on shock and collapse, this has now been revised and, based as it is on the splendid work of Crile, forms one of the best accounts of these interesting and important conditions we have seen in any surgical work.

We have much pleasure in again strongly recommending this book not only to the practitioners and house surgeons for whom it is intended, but to every one concerned in the successful after-treatment of operations.

INTERNATIONAL CLINICS. (b)

THE third volume of the fourteenth series of "International Clinics" is, like its predecessors, very nicely got up, both as regards paper, binding, and plates. The latter being fairly numerous, and is perhaps somewhat superior to the earlier volumes of the series in the general matter that it contains. A large number, however, of the papers that it includes, although no doubt excellent as clinical instruction for a class of students, are hardly what one would seek or expect to find in a volume of this kind.

The first 120 pages are devoted to the subject of syphilis, and to this part Fournier has contributed two very interesting papers. The first of these is entitled "Syphilis and Suicide," and is bound to attract the attention of every practitioner who has had an opportunity of observing the mental effects produced by an abrupt statement to a patient that he is suffering from syphilis. The second is a valuable addition to the discussion of the value of calomel injections. Dr. Fournier is in accord with most English physicians in holding that the hypodermic treatment is by no means essential or even advisable in ordinary cases of syphilis, but he points out that, in some of the more severe types of the disease when it is necessary to strike an immediate and heavy blow at the poison, no other method will give such quick and satisfactory results. Another interesting paper in this section is that on Acute Sypnilitic Nephritis by Chauffard and Gouraud.

(a) "The After-Treatment of Operations." By P. Lockhart Mummery, F.R.C.S., Eng., B.A., M.B., B.C.Cantab, Second Edition, pp. viii, 240, with 37 illustrations, crown 8vo. Price 5s. net. London: Baillière, Tindall and Cox. 1904.

(b) "International Clinics." A Quarterly of Illustrated Clinical Lectures. Edited by A. O. J. Kelly, M.D., Philadelphia. Vol. III. Fourteenth Series, 1904. London: J. B. Lippincott Co.

The remainder of the book is filled up with a miscellany of papers on therapeutics, medicine, surgery, and gynaecology. The only one that requires special mention is that on "Foreign Bodies in the Bronchi," by Lumoyez and Guisez. In it a most successful case of removal of a nail from a bronchial tube by Killian's method is described, and a short discussion of the method itself is appended.

INVALID FEEDING. (a)

IN spite of the anonymity of the authors the 250 pages comprised in this work contain much useful information. The literary style is rather slipshod but the instructions are clear and the nurse, as well as the housekeeper, will be enabled to enlarge the sphere of their operations, to the comfort and benefit of invalids in their charge. The first half of the book is devoted to the elementary treatment of "certain prevalent diseases and maladies" (why "and maladies"?) such as fevers, gout, consumption, diabetes, &c., the second part being given up to carefully selected recipes for the preparation of food for invalids.

The general principles laid down in the first part of the work are sound and many popular fallacies are held up to ridicule. Although a number of proprietary articles of food are referred to in the text their claims are never unduly thrust upon the reader, and some of them at any rate deserve attention at the hands of practitioners. In view of the importance of the question of nourishment in morbid states this volume may advantageously be studied by all who are concerned in ministering to the requirements of invalids. It will add to their resources and enable them to attenuate the monotony of the sick diet.

RICHARDS' PRACTICAL CHEMISTRY. (b)

THE object of this book is primarily to provide medical and dental students with an introduction to elementary qualitative and quantitative chemical analysis, but it will also prove acceptable to general students. It may be suggested that the enormous number of such books is already more than sufficient to meet the demand, great as that may be; but, as the author points out in the preface, "The recent revision of the practical chemistry of the Conjoint Board Preliminary Scientific Examination has rendered considerable modification in the course of study necessary, and the book contains all the subject-matter in the new syllabus, besides additional detection tables and volumetric analysis, arranged to meet the requirements of the Preliminary Scientific Examination of the London University." The author, from his position as a lecturer to medical students, should be well acquainted with the requirements of the examinations he caters for in this book, the usual tests are given with the usual information to give the student an idea of what he is doing. Probably the author has very good reasons for placing cadmium, chromium, manganese, cobalt, nickel, strontium and lithium in a special chapter labelled "Special Tests for Metals not included in the foregoing Table," but this is the only matter in which the reviewer is not in accordance with the author. A happy idea is the devotion of four pages to a list of a few salts offering special difficulties. Another three pages will appeal to candidates the night before the examination—namely, those devoted to some 110 equations bearing on the analytical work, though this is, of course, not the use for which they were intended to be put. Directions are given for the preparation of 27 salts, volumetric analysis is treated of in a simple way, and last, but by no means least,

Part IV. is devoted to Elementary Practical Toxicology; but it might be well to jog the student's memory, that, before applying the flame to Marsh's apparatus, the hydrogen should be tested, to ascertain that all air is out of the flask.

ORGANIC CHEMISTRY FOR BEGINNERS. (a)

THIS little book is an appendix to the author's "Text-Book of Organic Chemistry," which is now well-known as a students' manual in England. To students in any branch of chemistry practical work is essential in that branch, and books treating of practical organic chemistry being by no means numerous, it is scarcely necessary to indicate what a great aid it is, to both teacher and taught, when the book on practical work comes from the pen of the author of the text-book in use at their particular establishment. The English student using this manual has this advantage over students using the Dutch copy, in that not only has the whole text been revised, but some new experiments have been added by the author, and the result is a compact and useful little manual. In most laboratories there is a considerable waste of chemicals, and in a large establishment this waste is a serious item, therefore, those who have to account for the laboratory expenditure will appreciate the following extract from the author's preface: "In most instances I have indicated the weights or volumes suitable for the reactions, an experience of many years having taught me that students always employ much larger quantities than are necessary. The amounts prescribed are approximate, and, to ensure the success of experiments, need not be weighed or measured with great accuracy." The directions for performing the various experiments are given in a clear, lucid manner, and the experiments comprise all those that an elementary student is likely to require. All the necessary references are given to enable the student to at once refer to the larger text-book for the properties, &c., of the various substances.

A very full index brings this small manual to a close.

JAVAL'S "BLIND MAN'S WORLD" (b)

A PATHETIC interest environs this work, inasmuch as it records the thoughts, experiences, and feelings of one upon whom the calamity of total blindness fell at the comparatively early age of sixty-two years. The author is the well-known ophthalmic surgeon, Dr. Javal, and the object of his work is to supply a means for showing how blind persons like himself can make themselves in some degree independent of the "sighted," and thus to render their lot in life less irksome and more contented. In the pages of "The Blind Man's World" many details will be found by which this object may be attained. Deprived of his sight suddenly the author at once set himself to work to think out little "dodges" by which he could help himself. Here is one. "In my room I have two clocks, They do not keep exactly together, and so should the first strike when I am thinking of something else, though I may fail to count it, my attention is aroused, and I listen carefully for the second one to strike. Lastly, here is a trick for finding the time at night with only an ordinary watch. Wind your watch slowly precisely at the same hour as on the previous night, and count the clicks. Suppose, there are 144 clicks, then each corresponds to ten minutes. (24 hours = 1,440 minutes). If you wound your watch before getting into bed and want to know the time during the night, wind it again slowly. You will have been in bed ten minutes for every click you hear." Apparently the author has succeeded very well in lessening the

(a) "The Art of Feeding the Invalid." By a Medical Practitioner and a Lady Professor of Cookery. London: The Scientific Press, Limited. Price 1s. 6d.

(b) "Practical Chemistry, including Simple Volumetric Analysis and Toxicology." By P. A. Ellis Richards, F.C.C., Professor of Chemistry at Queen's College, London, Public Analyst to the City of Westminster; Analyst to Charing Cross Hospital; and Assistant Lecturer on Chemistry and Toxicology in the Medical School. Pp. viii.—186. Crown 8vo. 3s. net. London: Baillière, Tindall and Cox, 1904.

(a) "A Laboratory Manual of Organic Chemistry for Beginners." By Dr. A. F. Holleman, Professor Ordinarius in the University of Groningen, Netherlands. Translated from the Dutch by A. Jamieson Walker, Ph.D. (Heidelberg), B.A., Head of the Department of Chemistry, Technical College, Derby. 18mo., riv., and 78 pages. New York: John Wiley and Sons; London: Chapman and Hall, 1904. Cloth, 1 dol. net.

(b) "The Blind Man's World: An English Version of 'Entre Aveugles.'" By Dr. Emile Javal. Translated by W. Ernest Thomson, M.A., I.M.D. London: George Putnam's Sons, Ltd., 1904.

burden of his heavy misfortune. He delights in country and town walks, enjoys riding on a tandem tricycle, concerning which method of exercise he naively remarks "the adoption of an unvarying itinerary may be poor fun for the guide, but, I, at any rate, enjoy being able to determine exactly where I am at any minute"—amuses himself with writing by means of a special writing board for blind people, which he has introduced, plays games, and always keeps his mind busy in designing new schemes for improving his helpless condition. That the work is one which everyone should read, both for pleasure and profit, is the least that can be said of this book, which has been actually written by a blind man. The work of the translator has been faithfully performed.

Literary Notes and Gossip.

FIFTY years ago a "Woman's Year Book" (A. and C. Black) would have contained notes for crochet, jam making, bead flowers, etiquette, and cosmetics; to-day it shows an open door to every profession and business, but severely states conditions of entering, to deter any who "think" they could succeed. It is a most invaluable reference work for those who are frequently asked for information on every possible employment by other women.

DR. JOHN O'CONNOR's little book of directions, entitled "Aseptic Duties of a Surgical Nurse or Dresser," published in Buenos Aires, is a complete code of surgical morality in the matter of asepsis and antiseptics. It is interleaved so that further suggestions or directions can be added. No surgical nurse or dresser should be without it.

THE copyright of that most useful and popular handbook, "Half-hours with the Microscope," by Dr. Edwin Lankester, formerly published by Messrs. W. H. Allen and Co., has been acquired by Messrs. C. Arthur Pearson, Ltd., who have also purchased the companion volume by Thomas Davies, on "The Preparation and Mounting of Microscopic Objects." The latter has been out of print for some time, but a new and cheaper edition will be published very shortly.

We have received a copy of an account book called "The Simple Medical Year Book." It is intended to be used as a private ledger by practitioners. Each page affords space for a complete record of the week's income and expenditure. The various columns include fees earned, cash received, surgery expenses, salaries, and other outlays likely to be incurred in the management of a general practice. Tables are also given into which may be entered the total income and expenditure for the four quarters, as well as for the whole year. The book is prefaced by some useful hints on the preparation of income tax returns, a matter of very great importance to medical men. A series of indexed pages for memoranda is appended. The book is certainly one which is sure to find a large number of patrons, as it is not only most useful, but it is of small size and therefore easily handled. The price is 10s. 6d. net, and the publishers are Messrs. John Bale, Sons, and Danielsson, Limited.

THE Editor of that sterling monthly, the *Boy's Own Paper*, writes us that he is constantly receiving letters from schoolmasters, teachers, boys' brigade leaders, and other workers amongst the young, asking whether it would not be possible for him to produce also a cheap magazine for lads which could be used as a reading book in schools, as well as circulated widely as an effective antidote to the trashy and even morally pernicious stuff that is constantly pouring from the Press in order to catch the teeming scholars of elementary schools. After mature consideration, he informs us that he has determined to make the attempt to produce at a cost of one penny per month, a magazine that shall not only be of current interest, but also

be worth preserving and binding, for school libraries, boys' bookshelves, and the homes of the people. In his laudable attempt to stem the degenerate tide he will have the hearty approval of all right-thinking men.

Medical News.

Small-pox Outbreak at Bombay.

AN epidemic of small-pox is reported to be causing serious anxiety at Bombay. There have been a hundred deaths from the disease within a week in the city of Bombay, and there are hundreds of cases in the hospitals. The anxiety over the outbreak is aggravated by the reluctance of natives to be vaccinated and to submit to segregation.

A New Hospital Auxillary.

SIR FREDERICK TREVES, speaking last Thursday at a dinner given in aid of a Home of Recovery, to be built in Surrey (patroness, Princess Louise), said the present pressure on London hospitals was not brought about, as many imagined, by those coming who could afford help elsewhere. The population has increased enormously, yet neither in that did the reason lie, but in the fact of the astounding change which had taken place in surgery. He had been twenty-five years at one hospital, and on first entering there was one operating theatre occupied one afternoon a week for two hours. That same hospital had to-day six theatres open every day and nearly all day. Operations were now possible which fifty, even twenty years ago, would have been deemed hopeless and the suggestors madmen. The work had increased three hundred-fold. But the pathetic side was that even after skilful operation, patients had often, through pressure of space, to go away with wounds partly healed, and these cases no convalescent home would take. They drifted back to homes where stamp-paper, a hairpin and the family sponge were the only surgical tools. The scheme of a Home of Recovery was one of the wisest ever made, and would have the support of every London hospital. Over £1,300 was subscribed during the evening.

Royal College of Physicians of London and the Royal College of Surgeons of England—Diploma in Public Health.

THE following are the names of the seventeen candidates who are recommended by the Examiners for the diploma, viz:—Arthur Reginald Bankart (M.V.O.), M.B., C.M.Edin., John Cullen, M.D., Ch.B.Glas., Alfred George Edsell, M.D.Dur., L.R.C.P., M.R.C.S., L.S.A., William Lloyd Edwards, L.R.C.P., M.R.C.S., Edward Haines, L.R.C.P., M.R.C.S., Oswald Horrocks, L.M. and S.Madras; L.R.C.P. and S., F.R.C.S.E., Oliver Richard Archer Julian (C.M.G.), (Major, R.A.M.C.), L.R.C.P., M.R.C.S., L.S.A., Charles Randolph Kilkelly (C.M.G.) (Surg.-Maj. Grenadier Guards), M.B., B.Ch.Dublin; L.R.C.S.I., Frederick Norton Menzies, M.D., B.S., and M.R.C.P.Edin., Robert Macfarlane Mitchell, M.B., Ch.B.Edin., F.R.C.S.Ed., Arthur Hugh Morris (Capt. R.A.M.C.), L.R.C.P., M.R.C.S., Albert Pearse (Major R.A.M.C.), L.R.C.P., M.R.C.S., John Richards, L.R.C.P., M.R.C.S., Frank Edward Scrase, F.R.C.S., L.R.C.P., Harold Weightman Sinclair, M.D.Lond., L.R.C.P., M.R.C.S., Robert Small, L.R.C.P., M.R.C.S., Frederick Robert Elliston Wright, M.B.Lond., L.R.C.P., M.R.C.S.

IN our last issue we referred to the prize competition organised by Messrs. Wright, Layman and Umney, and remarked that it would be interesting to learn how the standard test number is arrived at. We now learn that the figures were arrived at in the following manner: All the numbers given by the competitors were added together and divided by the total number of competitors the number ascertained being 1702, and a cheque for £50 was sent to Miss Edith Burn, Didsbury, near Manchester, who alone sent in the correct figures. We understand that many thousands of people went in for this competition throughout Great Britain and Ireland, and therefore it represents the exact average, which is approximately one which might have been expected.

Notices to Correspondents, Short Letters, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive Signature or Initial*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

CONTRIBUTORS are kindly requested to send their communications if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in re-forwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

ORIGINAL ARTICLES or LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the publisher of printer before the type has been distributed. This should be done when returning proofs.

TEST.—In chronic urethritis a capable use of the urethroscope will in most cases locate the infected area.

COUNTRY SURGEON.—Correct glasses avail little or nothing if the frame be ill-fitting. Take the pupillary distance, height of bridge, angle of crest of bridge, width of bridge on pupillary line, width of bridge at base, depth of bridge, temple length, temple distance. Submit this to a respectable optician who is not certified by the Spectacle Makers Company.

DISPENSER (Surbiton).—It is not an uncommon experience that drugs given for an entirely different purpose have relieved symptoms it was not proposed to treat. Needless to say that fact does not warrant haphazard prescribing.

DR. P. S.—Rosenbach's *Physician v. Bacteriologist* has been translated into English by Dr. A. Rose, New York. Rosenbach is the author of over twenty books, and contributed to Nothnagel's Encyclopaedia. It is a good book of reference.

F. K. BOBSON (Lancs.).—The best plan of meeting the difficulty is to induce the local sanitary authority to institute a system of free bacteriological tests. Where diphtheria has so firm a hold over an insanitary district such as you describe the only hope of making headway lies in the early detection of cases, and that again depends in many instances entirely on early bacteriological diagnosis.

DR. M. C.—Our inquiries have elicited nothing definite, but we understand there is a probability that the matter will be brought up at the next meeting of the Council.

L.R.C.P., M.R.C.S.—The most practical, and at the same time, the most successful "Manual of Medicine," which has come under our notice is that by Dr. Monro of Glasgow. It occupies a position midway between the larger "systems" and the smaller so-called cram books, and is excellently suited to the requirements of men in general practice.

MR. A. WILSON HOGG is thanked for report of case, which is marked for early insertion.

ESQUIRER.—The person referred to is a quack of the worst type. Have nothing to do with him, his guarantees are a sham and a snare for your money. You may if you please give him this as our testimonial.

HY. S. WILSON.—We do not prescribe in these columns, and you may take it as a rule, with few exceptions, that where this is done in lay journals, the prescription by post is valueless as without personal examination and interrogation, a correct view of disease cannot be formed.

DR. HYSLOP is thanked for his communication.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, FEBRUARY 22nd.

HUNTERIAN SOCIETY (London Institution, Finsbury Circus, E.C.).—8.30 p.m. Paper:—Mr. A. H. Tubby.

MEDICAL GRADUATES' COLLEGE and POLYCLINIC (22 Chenies Street, W.C.).—4 p.m. Mr. A. H. Tubby: Clinique. (Surgical.) 5.15 p.m. Dr. F. Horrocks: A Case of Concealed Menstruation with Remarks on Treatment.

CENTRAL LONDON THROAT and EAR HOSPITAL (Gray's Inn Road, W.C.).—5 p.m. Demonstration:—Dr. W. Wingrave: Ear.

THURSDAY, FEBRUARY 23rd.

MEDICAL GRADUATES' COLLEGE and POLYCLINIC (22 Chenies Street, W.C.).—4 p.m. Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m. Mr. E. Clarke: Ocular Headache: Its Causes, Diagnosis, and Treatment.

MOUNT VERNON HOSPITAL for CONSUMPTION and DISEASES of the CHEST (7 Fitzroy Square, W.).—5 p.m. Lecture: Dr. T. N. Kelynaok: The Diagnosis and Treatment of Pulmonary Cavities (Post-Graduate Course.)

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—4.30 p.m. Dr. G. N. Meachen: Demonstration of Skin Cases.

FRIDAY, FEBRUARY 24th.

CLINICAL SOCIETY of LONDON (20 Hanover Square, W.).—8 p.m. Exhibition of Clinical Cases followed by Discussion. Patients will be in attendance from 8 to 9 p.m.
MEDICAL GRADUATES' COLLEGE and POLYCLINIC (22 Chenies Street, W.C.).—4 p.m. Dr. L. Lack: Clinique. (Throat.)

MONDAY, FEBRUARY 27th.

ODONTOLOGICAL SOCIETY of GREAT BRITAIN (20 Hanover Square, W.).—The Chair will be taken at 8 p.m. Casual Communications will be given by Mr. Stanley P. Mummery, L.R.C.P., M.R.C.S., L.D.S.Eng., on "A reliable Method of Bleaching Teeth," and by Mr. Frank Morley, L.R.C.P., M.R.C.S., L.D.S.Eng., on "A Case of Gangrene of the Lung following Tooth Extraction." A paper will be read by Mr. A. Hopewell-Smith, L.R.C.P., M.B.C.S., L.D.S.Eng., on "Some rare Anomalies of the Teeth." The Paper will be illustrated with Lantern Slides and Microscopic Preparations.

TUESDAY, FEBRUARY 28th.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—8.30 p.m. Dr. H. Corner: Demonstration on General Paralysis at Colney Hatch Asylum, New Southgate, N.

Vacancies.

Abergwynn Workmen's Medical Fund—Fully qualified Practitioner, to take charge of the practice. Salary £400 per annum. Applications to Thos. Bevan, 40, High Street, Abergwynn, South Wales.

Denbighshire Infirmary, Denbigh.—House Surgeon. Salary £100 per annum, with board, residence, and washing. Applications to J. Parry Jones, Secretary.

Open-air Treatment.—High-class Sanatorium.—House Physician. Salary £130 per annum, with board and residence. Applications to Physico, care of Gould's Advertising Agency, 54 New Oxford Street, W.C.

East London Hospital for Children and Dispensary for Women, Shadwell, E.—Medical Officer for the Casualty Department. Salary £100 per annum. Applications to Thomas Hayes, Secretary.

North Cambridgeshire Hospital, Wisbech.—Resident Medical Officer. Salary £100 per annum, with furnished rooms, attendance, coal, gas, and washing, but not including board. Applications to William F. Bray, Secretary, Wisbech.

Kensington Board of Guardians.—First Assistant Resident Medical Officer. Salary £120 per annum, with apartments, board, and washing. Applications to the Clerk to the Guardians, 3, Carlos Road, Kensington.

Royal Buckinghamshire Hospital, Aylesbury.—House Surgeon. Salary £100 per annum, with board, and furnished apartments. Applications to Geo. Fell, Secretary, Rickford's Hill, Aylesbury.

Birkenhead and Wirral Children's Hospital, Woodchurch Road, Birkenhead.—Male House Surgeon. Salary £100 per annum, with board, residence, and laundry. Applications to F. W. Archer, 25 Storeton Road, Birkenhead.

Lincoln County Hospital.—Senior Male House Surgeon. Salary £100 per annum, with board, lodging, and washing. Applications to the Secretary, 2 Bank Street, Lincoln.

Appointments.

BROWN, A., L.R.C.P.I., M.R.C.S.Eng., Certifying Surgeon under the Factory and Workshop Act for the Masham District of the county of York.

BURSHARD, F. F., M.D., M.S.Lond., F.R.C.S.Eng., Consulting Surgeon to the Bromley Cottage Hospital.

BURTON-BROWN, F. H., M.D.Oxon, Clinical Assistant to the Chelsea Hospital for Women.

DOORLY, P. F., L.R.C.P., M.R.C.S.Edin., L.F.P.S.G., Certifying Surgeon under the Factory and Workshop Act for the Carrick-on-Shannon No. 2 District of the county of Roscommon.

FORTESCUE-BRICKDALE, J. M., M.A., M.D.Oxon, Out-patient Physician and Pathologist to the Royal Hospital for Sick Children and Women, Bristol.

GEDGE, ARTHUR SYDNEY, M.R.C.S., L.R.C.P.Lond., Medical Officer for the Fifth District of the Devises Union.

HARRIS, WILFRED J., M.D.Cantab., Physician in Charge of Out-patients at St. Mary's Hospital, Paddington, W.

Births.

PRITCHARD.—On February 17th, at Wellington Square, Hastings, the wife of W. Clowes Pritchard, M.R.C.S., L.R.C.P., of a son.

Marriages.

SHERRARD-CRAIG.—On February 17th, at the Cathedral, Bombay, James William Sherrard, Indian Army, son of Colonel C. W. Sherrard, R.E., to Margaret, only daughter of James Craig, M.D., Beckenham.

Deaths.

TOMLINSON.—On February 17th, at 8 Earl's Avenue, Folkstone, Lt.-Colonel Edward Denham Tomlinson, M.D., late of the R.A.M.C. and York and Lancaster Regiment, in his 69th year.

The Medical Press and Circular.

DERMATO-MYOSITIS OR ACUTE POLYMYOSITIS.

By WILLIAM MURRELL, M.D., F.R.C.P.,

Physician to the Westminster Hospital; Lecturer on Clinical Medicine and Joint Lecturer on Medicine.

IN most text-books on medicine there is a short article on myositis, or inflammation of the muscles, but that particular variety known as dermatomyositis is rarely referred to or is merely mentioned. Cases of this disease are so uncommon in this country that the name is practically unknown. The following case seems worthy of record:—

A woman, æt. 23, after an illness of three weeks' duration, was admitted on December 6th, 1904, with febrile disturbance and tenderness of the voluntary muscles. The temperature ranged daily from 99.8° to 102.8°. The muscles of the arms and legs, of the thorax and abdomen, of the back and neck, were equally affected. The slightest pressure gave rise to lively manifestations of pain. The tenderness was not along the course of the nerves and none of the articulations were involved. There was some œdema of the ankles, and there had been some of the face. The urine contained no albumin. The red blood corpuscles numbered on admission 5,580,000 per c.mm., and the white 28,000, with hæmoglobin 80 per cent. Three weeks later, when the acute symptoms had subsided, the reds were 4,200,000 and the whites 19,600, with hæmoglobin 70 per cent. The attack commenced with tonsillitis and pain and swelling on the left side of the face, and there was gastro-intestinal disturbance for a day or two. There was profuse sweating, but no eruption. There was a history of pains in the thighs, both back and front, in the calves, in the dorsum of the feet for a fortnight, and of pains in the flexor aspect of the arms and forearms for a week. A difficulty had been experienced in walking and in moving the arms and fingers. The deep reflexes, with the exception of that of the right triceps, could not be elicited. There was no wasting and no fibrillation. The patient had always resided in London, and there was no history of any previous illness with the exception of gastric ulcer with hæmatemesis at the age of 17. The patient had not menstruated for three months, but there was no disease of the pelvic organs.

Trichiniasis was suspected, and under an

anæsthetic a considerable fragment of the gastrocnemius and soleus was excised, but no trichina spiralis could be detected. Sections of the muscles were cut, and were normal in appearance. The motions were carefully examined, but nothing was found. Widal's reaction was not given. The fever gradually subsided at the expiration of ten days from admission, but the tenderness persisted for a fortnight longer, becoming little by little less acute. The patient was kept under observation for another month, but there was no further development.

This case presents many points of interest. It was clearly not an ordinary case of muscular rheumatism. In that complaint there is usually a more or less definite history of exposure to wet or cold. As a rule, although not invariably, one group of muscles, or groups of muscles functionally related, is attacked. This is so generally recognised that the nomenclature is typographical. There is little or no constitutional disturbance, and there is little if any elevation of temperature. This last fact is well illustrated by a very severe case of muscular rheumatism recently under my care. The patient was a carpenter, æt. 34, living at Eastbourne. Towards the end of January he was attacked suddenly with pain and stiffness in the muscles of the left thigh, in the right biceps and lumbar region. He stated that for some days previously he had been working in an open shop exposed to a cold east wind. He sought relief not because he felt ill, but from his inability to follow his occupation. His temperature was taken systematically for ten days, and only twice rose to 100° F.

The probabilities are that the case here recorded was a toxic myositis, the point of entrance of the poison being the tonsils. It bears a striking resemblance to the disease known as dermatomyositis, although some of the characteristic symptoms were absent. Dermo-myositis is rare in this country, but several cases have been recorded in Germany, and it is said to be common in Japan. It was not known as a clinical entity until 1887, when P. Hepp, (1) E. Wagner, (2) and Unverricht (3) each independently described an unknown disease so closely resembling trichiniasis in its features that it was called by the first-named "pseudo-trichiniasis," a form of nomenclature utterly indefensible. In 1891 Unverricht (4) published his second case, and suggested the term dermatomyositis. Prior to Unverricht's first publication, Wagner (5) in 1863 had described "A Case of Rare Muscular Disease," and in 1875 Potain (6) had recorded a somewhat

similar case, but regarded it as a chronic morvian disease, a kind of bastard glanders, with anomalous symptoms. In 1897 Kürt von Bultzingslöwen, of Breslau, (7) published a thesis of thirty pages, and a temperature chart on dermato-myositis. The first case in France, with the exception of Potain's, occurred in the clinique of Professor R. Lépine, of the Hôtel-Dieu at Lyons, and was reported by Dr. L. M. Bonnet (8). In 1903 Dr. F. Frochheimer, of Cincinnati, (9) published a detailed account of a typical case in a woman, æt. 40. Last year Dr. John Hill Abram, (10) of the Liverpool Royal Infirmary, published two cases of infective myositis, one of which was clearly septic in origin, and proved fatal.

The symptoms of dermo-myositis are fairly constant and characteristic. The onset is gradual, and little or nothing is known as to its causation. The fever is continuous, except in the septic cases, and never attains a high degree of intensity. There is always pain and tenderness of the muscles, with usually a considerable amount of œdema. The muscles may be attacked simultaneously or successively. When the muscles of the pharynx and larynx are involved death usually ensues from aspiration pneumonia. The spleen in most cases is enlarged. There is usually profuse sweating, and there may be eruptions of various kinds, especially erythema, urticaria, and herpes. It is not essential to the diagnosis that all these symptoms should be present, and in one of Unverricht's cases there was no fever, no sweating, no enlargement of the spleen, and no rash. In the present case, the patient was ill for three weeks before she came under observation, and it is possible that during that time there may have been a rash of which we have no record. The high percentage of red and white blood corpuscles, especially the latter, is notable. In Frochheimer's case the erythrocytes numbered only 4,102,000, and the white cells 5,200 per c.mm. The duration of the disease is variable. It may run an acute course in from one to eight weeks, or it may become chronic, lasting a year or more. In one case convalescence was greatly prolonged, and the patient had not fully recovered at the expiration of two years. The prognosis is by no means good, and in 15 cases there were 11 deaths, of which 6 were from secondary pneumonia.

There are many other forms of polymyositis. In September, 1888, Dr. George W. Jacoby, of New York, (11) read before the American Neurological Association a paper on "Subacute Progressive Polymyositis," in which he gave a comprehensive review of our knowledge of the subject. Lorenz, in 1898, in an article in "Nothnagel's Encyclopædia," collected seventeen cases of muscle inflammation, and classified them. The myositis due to traumatism or operative measures falls within the province of the surgeon. Enteric myositis, a waxy or granular degeneration of the striated fibres, is not uncommon, but the symptoms are slight and the pain and tenderness on pressure are never pronounced. It has been seen in cases of scleroderma, and gonorrhœal myositis, affecting chiefly the muscles of the neck, is not unknown. Suppurative myositis is usually due to streptococcus infection, and is best treated with serum. In some cases there are various forms of hæmorrhage, and in others the disease is associated with erythema nodosum. The chronic form may be the precursor of myositis ossificans,

and two years ago I had in the hospital a man, æt. 34, in whom every muscle of the body showed ossification.

THE LINCOLN EPIDEMIC AND THE LATENCY OF ENTERIC FEVER INFECTION.

By P. G. GRIFFITH, M.B., B.Ch.

Horsney.

THE outbreak of typhoid fever in Lincoln prompts me to anticipate somewhat the results of an investigation I have been engaged in for some time with regard to the etiology of this disease, since it seems possible that the conclusion I have already arrived at may be of some small value. The objects I have in view in pursuing the investigation referred to are to determine the lethal effect of the gastric and pancreatic juices on typhoid bacilli and to ascertain if these organisms are often present in the alimentary canals of healthy subjects without producing typhoid fever.

The influence of the digestive juices on the specific organism of typhoid fever seems to have been overlooked as a factor in the etiology of the disease. By one authority it is stated that gastric juice kills *B. typhosus* in ten minutes. My own experiments do not confirm this, but as far as they go it appears safe to assume that an exposure for two hours to healthy gastric juice at the body temperature is fatal to their existence. Pancreatic juice appears to have an equally fatal influence. It is therefore probable that when these organisms are introduced into the alimentary canal of a healthy individual *with* food, their chance of surviving until they reach a place of safety in the lower ileum, where pancreatic digestion ceases, is exceedingly remote. It is otherwise when the organisms obtain admission in water partaken of apart from food or in any other liquid whose presence does not act as a stimulus to the secretion of the digestive juices. Water when so imbibed in any quantity passes almost immediately from the stomach to the small intestine and finds its way to some extent to the lower bowel before it is all absorbed. A ready means is thus provided for the bacilli to escape the destructive influence of the digestive juices.

But it is more than probable that the bacilli may thus secure admission to the lower alimentary canal, and yet fail to produce typhoid fever, or to do so after a much longer interval than has been considered possible. The following considerations appear to render this a certainty. In an epidemic that occurred in Armagh in 1902 the conditions were such that the possibility of secondary infection could be excluded, yet in no less than 29 cases the disease was developed at

periods ranging from 25 to 46 days from the first time of exposure. In these cases the specific organism of the disease must have found a resting place in the intestines for weeks before it was able to effect an entrance to the tissues. In the *British Medical Journal*, 1902, vol. ii, p. 839, a suggestive case is recounted where exposure to infection ceased on January 15th, but the disease did not develop until the end of April. Chantemesse and other observers have discovered the typhoid bacillus in the stools of healthy individuals and in those of patients recovering from typhoid forty-six days after the cessation of fever. Taking these facts into consideration, with the knowledge we possess of the viability of the organism under conditions such as it would encounter in the lower alimentary tract, it is impossible, I submit, to come to any other conclusion than that it must be a common occurrence for individuals to harbour typhoid bacilli for considerable periods before they are infected with the disease or without suffering any inconvenience at all.

Under such circumstances the condition of immunity acquired by a previous attack or one artificially induced must be an important factor in the prevention of the disease, but I submit that of even greater importance is the condition of the mucous membrane of the lower alimentary tract. The frequency of relapses, or re-infections, as I would call them, in this disease is a strong proof of the feeble immunity conferred by an attack, and the well-known danger of improper feeding in the period of convalescence appears to me to be due to its evil effect on the alimentary mucous membrane lessening the resistance of the latter to a second invasion.

Dr. Howard Tooth, in an account of his experience of this disease in the South African war, suggested the probability of the bacilli finding a temporary home in the intestinal canal. He says: "It is conceivable, nay more probable, that every man in these great camps may have at times received into his alimentary canal enteric bacilli which may have grown and multiplied, but without producing the characteristic disease." And later he goes on to say: "We were struck by the fact that in many of our cases the enteric fever attack appeared in the course of dysentery. I strongly suspect that the two diseases may co-exist, and that such a conjunction may be of unfavourable omen. . . . Diarrhoea and dysentery in themselves proved as a rule very amenable to treatment, but in the light of the foregoing remarks the slightest diarrhoea becomes invested with a new importance."

The virulence of the typhoid bacillus has been shown experimentally by Sanarelli to be much increased by the presence in the blood of the toxins of other organisms such as the *Bacillus coli*, and to this Dr. Tooth attributed the danger of minor intestinal derangements. But it appears to me probable that an even more pernicious influence may be exercised by them in their destructive effect on the lining of the alimentary tract. They break down the most important defence to the typhoid invasion and increase the force of that invasion indefinitely—so that no immunity that Nature or art can bestow is sufficient to withstand the attack.

If the etiology of typhoid be looked at from the standpoint I have endeavoured to elucidate,

an explanation will be found for a very striking peculiarity of all water epidemics of any magnitude, *viz.*: the continuance of the epidemic for some time after the polluted water has been cut off. For example—in the Maidstone epidemic of 1897 the polluted water was cut off in the first week of October, yet no less than 134 cases fell between October 20th and November 20th. These were described at the time as secondary cases, and while this is doubtless true with respect to a certain small proportion of them, it is far more likely that the majority contracted the disease from the infected water.

In Lincoln there are probably many people now who are the unwilling hosts of typhoid bacilli, multiplying in number, and waiting a favourable opportunity for attack. Nor is the danger confined to the hosts alone, for they may also be the unwilling cause of infecting others, since it is more than likely that many of these people, without ever suffering themselves, may yet act as disseminators of the disease.

THE TREATMENT OF CONVALESCENCE:

WITH SPECIAL REFERENCE TO THE VALUE OF
IRON.

By JAMES BURNET, M.A., M.D., M.R.C.P. Edin.,
Senior Clinical Tutor, Extramural Wards, Royal Infirmary;
Registrar, Royal Hospital for Sick Children; and Physician
to the Marshall Street Dispensary, Edinburgh.

IN considering the treatment of disease we are all somewhat apt to regard lightly, or even in some cases to neglect altogether, the period of convalescence. Still, if we reflect for a moment, we at once recognise that treatment does not really end until the period of convalescence is over, and the patient has resumed his every-day duties. There is no doubt that many serious organic changes take place during convalescence from acute disease. All serious illness weakens the various organs, more especially the heart, lungs, kidneys and central nervous system. These organs are all more or less affected by the onset, and during the progress of any acute illness. Hence we are not surprised to find that during convalescence a patient may become affected by some secondary disease which may in some instances tend greatly to shorten his life.

Convalescence may be rapid or it may be retarded. This will, to a certain extent, depend on the recuperative power of the patient, but also largely on the management and treatment of the convalescent period. Slow and greatly retarded convalescence is seen after influenza, enteric fever, and acute rheumatism, as well as after certain surgical affections. It is also apt to be prolonged in some of the diseases of childhood, such as pneumonia, and especially rheumatic heart conditions. Again we observe that after serious labours, especially those involving much loss of blood, the period of convalescence is very slow and uncertain.

Now what does this retarded convalescence mean to the individual? It prevents his returning to work—an important matter in the majority of cases. Again, nervous and intellectual vigour are apt to become impaired, while at the same time the general bodily strength becomes more and more enfeebled. In the case of female patients there is always the danger lest a condition of chronic invalidism and of neurasthenia become developed; while children run the risk of retarded growth, both of body and of brain. Apart, however, from these considerations we have to remember that when the tissues have become weakened by disease the entrance into them of other pathogenic organisms becomes an easier matter, and it is during the period of convalescence that this inroad is most likely to take place. For example, most of us have seen cases in which a patient recovering

with difficulty from some severe illness has developed tuberculosis, especially where there was a previous predisposition to the disease. In other cases we find that pernicious anæmia, and even malignant changes, have had their origin during the convalescent period, especially where the latter was slow and unsatisfactory.

In view of what we have stated, it will be at once apparent that it is a grave mistake to deal carelessly with patients during their convalescence. Their treatment at this stage is often of the utmost importance, while in not a few cases their future well-being may largely depend on the care with which we bring them back through convalescence to a state of more or less perfect health and strength.

We may look at the treatment of convalescence under three headings—(1) Dietetic, (2) Hygienic, and (3) Medicinal.

Regarding the dieting of patients during convalescence little need be said, save to remind ourselves of the fact that the question of diet is very much neglected, and yet we must in every case strive to appeal to our patient's appetite by presenting to him such food materials as are both pleasing to the palate and at the same time of sufficient nutritive value. As a general rule convalescent patients require much food, and the more they can be coaxed to take the better. It may be well to point out that medicated wines are seldom commendable, and in the case of female patients to be avoided altogether lest intemperate habits be formed. In ordinary cases, however, burgundy, port wine, and it may be whisky, are sometimes prescribed with advantage.

The hygienic measures to be adopted during convalescence are those which govern our everyday practice. Abundance of fresh air and sunlight are necessary in every case, and we must see to it that the patient obtains these as far as possible. Change of air and scene will usually produce beneficial effects, especially after depressing illness, such as influenza.

The medicinal treatment of convalescence must be referred to at somewhat greater length, as it is the mode of treatment which often proves so unsatisfactory. Tonics are indicated in practically every case; but all cases are not alike, and consequently the form of tonic which is prescribed with most satisfactory results to one patient may fail altogether in its therapeutic effect when given to another. It is not by any means an easy matter to explain why this should be, but that such is the case must be the experience of every physician. Probably the solution to the difficulty is obtained by inquiring carefully as to the ultimate cause of the retarded convalescence in every individual case. When we do this it will not infrequently be found that a condition of anæmia has been induced, and until this has been got rid of we cannot possibly expect the patient to be well and able for his duties.

Anæmia is certainly largely accountable for the retarded convalescence following on acute rheumatism, nephritis, enteric fever, childbirth and surgical operations generally. This being so, how are we to deal with this secondary anæmia? The erythrocytes may be as low as 2,500,000 per c.mm., and the hæmoglobin 40 per cent. or even less. In such cases little or no benefit will result by giving either hypophosphites or glycerophosphates, though these are largely prescribed at the present time. Neither can we expect any good results from arsenical preparations, or from those containing manganese. It is iron that we look to in such cases as our sheet anchor, but much will depend on our choice of the preparation to be given. The perchloride is too astringent, upsets the stomach and produces constipation, with a coated tongue as well as loss of appetite. The same objections may be raised against the sulphate. The saccharated carbonate is more satisfactory, but its action is too slow for our present purpose. What we need is a remedy which will produce immediate and rapidly progressive benefit to the convalescing patient. Recently a preparation, known as iron vitellin, has been exten-

sively used here and abroad, and in it we believe a distinct advance has been realised in iron therapy.

Iron vitellin, or, as it is otherwise termed, ovoferrin, is an organic compound produced by Drs. A. C. Barnes and Hermann Hille, of Philadelphia. It is a clear, red fluid, with neutral reaction, and both odourless and tasteless. Its chemical formula is $C_6 N_7 S, H_3 Fe_3 O_{22}$. It is synthesised from serum albumen and iron tartarate, and is undoubtedly a true metallo-organic derivative. The minimum dose is two drachms thrice daily, in a wineglassful of water. Apart altogether from its use in convalescence, it may be given to children, and at present we are engaged in a series of observations in connection with this valuable use of it. Recently it has proved of service in the treatment of pernicious anæmia.

The following brief notes of actual cases in which iron vitellin was employed show that it acts better in convalescence than do the usually employed tonics and reconstructives.

CASE I.—A. Y., a girl, æt. 7, who had been operated on for enlarged tonsils and adenoids. She remained feeble and had no appetite. Various remedies were tried, including cod-liver oil and two preparations of iron. Finally, recourse was had to iron vitellin, at first in teaspoonful doses, later in tablespoonful, and finally in one ounce doses. Under this treatment the child rapidly regained strength, the colour returned to her face, and a month later she was in the enjoyment of perfect health.

CASE II.—J. M., male, æt. 24, had a severe attack of enteric fever with high temperature. He had a plentiful eruption of typical spots, and for a fortnight there was fairly profuse diarrhœa. It was not until the beginning of the fifth week that the temperature fell to normal. Ten days later he was placed on light solid food, but his progress towards convalescence was slow. For a fortnight he was so weak that it was only with difficulty that he could walk a few steps into an adjoining room. Change of air was tried, and he was sent to the seaside, where he remained for three weeks. While there he improved somewhat, but his powers of locomotion were very limited, and there was complete incapacity for mental exertion. He was put first on hypophosphites and then on glycerophosphates, but without much improvement resulting. An examination of the blood was then made, when it was found that the red cells numbered 3,400,000 per c.mm., the leucocytes 7,000, while the hæmoglobin was reduced to nearly 40 per cent. This seemed to be a clear indication for the use of iron, and accordingly iron vitellin was given in full doses three times daily. At the expiration of a week the red cells numbered 4,240,000 and the hæmoglobin was 52 per cent., while there was a notable improvement in the patient's condition, physical as well as mental. Another week of the same treatment was marked by still further improvement, and he was now able to walk a considerable distance without difficulty or fatigue. He regained his appetite, and from being pallid and flabby rapidly put on flesh. The red corpuscles were now 4,960,000, and the hæmoglobin was 50 per cent. From this time he progressed steadily, and eventually made a complete recovery.

CASE III.—C. R., male, æt. 35. This was a bad case of influenza, complicated with pneumonia. The patient led a sedentary and studious life. He had had four previous attacks of influenza, although none of them were of so serious a type or attended by complications. He was left weak and destitute of energy. He had little or no initiative power, and found that the slightest effort at writing even a simple letter left him tired and exhausted. He was markedly anæmic, his red corpuscles being only 3,150,000 and the hæmoglobin scarcely 35 per cent. He was placed on reduced iron, but this produced nausea, and entirely upset his digestion. It was persevered with for ten days, but with practically no improvement either in his symptoms or in the condition of the blood. Iron vitellin was then tried, cautiously at first, and then in larger doses. At the expiration of a fortnight, the

red corpuscles had increased exactly one million, and the percentage of hæmoglobin had risen to 49 per cent. A fortnight later his lassitude had entirely disappeared, the red cells were 5,100,000, and the hæmoglobin was found to be 57 per cent.

Equally favourable results were obtained in two cases of fibroid disease of the lungs in which iron vitellin was administered regularly and in full doses.

CASE IV.—T. R. This was the case of a lad about 16 years of age, who had repeated attacks of profuse epistaxis which were checked with difficulty. The bleeding was entirely from the right nostril and a tender spot was found on the anterior part of the septum. The patient looked very ill and anæmic, and suffered greatly from headache and lack of strength and energy. Various local astringents had been tried, but these only gave temporary relief, and the bleeding recommenced as soon as they were discontinued. A blood count was then made, and this showed that the red cells only numbered 3,950,000, the hæmoglobin being 44 per cent. The patient was given iron vitellin three times a day for four days, when the red cells numbered 4,320,000, with hæmoglobin 48 per cent. Four days later, under the same treatment, the red cells had risen to 4,850,000 and the hæmoglobin to 53 per cent. On the expiration of another four days the red cells were found to be 5,260,000, and the hæmoglobin 60 per cent. The patient's general condition was improved to a marked extent under this treatment. His appetite was greatly increased, the bowels became more regular in action, and the patient's capacity for work was distinctly increased. There has now been no return of the epistaxis for nearly three months, but the patient still continues to take iron vitellin from time to time.

CASE V.—R. M., æt. 56. This patient was a business man, stout and flabby, who habitually dined well and took no exercise. He had long suffered from internal hæmorrhoids which caused him no little inconvenience. His liver was considerably enlarged and the urine was loaded with urates, while it contained more than a trace of albumin. An examination of the blood showed that, in spite of his plethoric appearance the patient was really anæmic. His erythrocytes numbered only 3,700,000 per c.mm., while the hæmoglobin was reduced to 40 per cent. This was the average of several observations. The question of operation was discussed but negatived. He was given a mixture containing sulphate of iron with sulphate of magnesia, but this produced headache and much distress, probably due to the condition of his arteries. He was induced to give up using purgatives, and was ordered a drachm of iron vitellin in a wineglassful of water thrice daily. After the third day the bowels acted naturally. The dose was then increased to half an ounce. At the expiration of four days the red cells had increased to 4,000,000, and the hæmoglobin by 4 per cent. A week later his red cells were 4,800,000 and there was still further improvement in the hæmoglobin percentage. He continued taking the iron vitellin for a month, and little by little the bleeding from the piles ceased. He soon regained his accustomed mental energy, and is now in the enjoyment of fairly good health.

In addition to the above cited cases we have used iron vitellin in the treatment of a number of other patients convalescing from typhoid fever, influenza, pneumonia, diphtheria, and rheumatic fever, and have been much impressed with its influence in increasing the blood constituents, and in improving the tone and general well-being. An analysis of these results concerning the effects of iron vitellin in convalescence and in secondary anæmia warrant the following conclusions:—

1. It is readily assimilated. It does not blacken the teeth, and it does not upset the stomach, nor produce constipation or headache.
2. As a tonic it acts promptly and rapidly, while its administration may be continued for long periods without producing deleterious effects.
3. It is palatable and absolutely non-astringent.

4. It acts powerfully as a hæmatinic, and also specifically by imparting tone to the system.

The Out-Patient Departments.

NATIONAL HOSPITAL FOR DISEASES OF THE HEART.

Case of an Unusually Slow Pulse.

By R. O. MOON, M.D. Oxon., M.R.C.P.,
Physician to the Hospital.

A.W., a carpenter, æt. 58, came up to my out-patient department at the Heart Hospital, in January, 1904, with the not uncommon complaint of "pains round the heart, flatulence and fainting attacks." To my surprise, on putting my fingers on his pulse, there were only twenty-six beats in the minute. It was, however, quite regular and of moderate tension. On examining the heart, it was clear that the apex beat and radial pulse fully corresponded. The impulse was in the normal position, but slightly diffuse; there was no murmur or anything unusual in the sounds of the heart.

Family History.—He comes of a healthy and long-lived stock, his father having lived to the age of ninety-nine, and his mother to ninety-six.

Previous History.—He says that he has always enjoyed excellent health until four years prior to his coming to the hospital, having seldom had to see a doctor. He had, however, twelve years ago a mild attack of influenza, in the course of which he recollects the doctor having commented on the slowness of his pulse, but it certainly caused him no symptoms at that time. Eight years later, in 1900, while on some scaffolding, he suddenly fell backwards in a faint, and would have fallen from a great height had he not been supported by a bricklayer who was standing by. For the next week he felt quite well, and then had another similar attack. After that they recurred at intervals of six months, until June, 1903, when they began to come on with great frequency—several times a week. In an attack he would fall to the ground with the suddenness of an epileptic seizure, remain unconscious for half a minute, and then, on regaining his senses, feel perfectly well. On two occasions he injured his head slightly in these attacks; he had, however, never bitten his tongue nor passed his water, and, as far as I could gather, there had been no convulsive movements. These attacks came on while he was quite quiet and making no exertion of any kind. He also suffered from vertigo and had attacks of syncope while in bed.

His general appearance is that of a strongly-built, vigorous, and very healthy-looking man. Before he became subject to these attacks, he was in the habit of taking a good deal of exercise—walking ten miles a day in addition to his work as a carpenter, which was rather of a skilled nature, not involving severe manual labour. There is no history of lues, and as regards alcohol he has been very moderate. He has, however, been a heavy smoker of late years. Up to the age of forty he had been quite moderate in this respect, but he then began to smoke about one ounce per diem of best shag, though for a few months before I saw him he had reduced this. He has also been a large meat-eater.

He came into the hospital for six weeks (February to March, 1904), and improved very much as regards his symptoms. The pulse-rate varied between a minimum of twenty-six and a maximum of thirty-six at different times, but was always regular; it did not appear to be accelerated by position, stimulation, or exercise. Sphygmographic tracings showed a slow pulse and nothing more. While in the hospital a soft, blowing systolic murmur developed, limited to the apex. He had several fainting attacks, being unconscious from ten to twenty seconds, and on two of these occasions the limbs were observed to twitch, but there was no alteration in the pulse-rate. The urine showed no trace of albumin, the optic discs were healthy, no signs of arterio-sclerosis, the lungs were slightly emphysematous, and the temperature was subnormal.

throughout his stay in the hospital. For the last ten months he has been much better in every way, having no cardiac pains or vertigo, and very little flatulence; he has only had three syncopal attacks, and has been able to do his work in moderation. The systolic murmur at the apex has, however, become more pronounced, and is now traceable into the axilla. The pulse continues to be regular and the rate is usually thirty when he comes up to my out-patient department.

As regards treatment, I have reduced his tobacco to one pipe a day, and also cut down the amount of meat he was taking. He seems to derive benefit from moderate doses of strophanthus, and for some months has been having

Tinct. strophanthi, 7min.;
Sp. ammon. aromat., $\frac{1}{4}$ drms.;
Aq. ad. 1 oz.;

t.d.s., together with an occasional dose of a carminative mixture for attacks of flatulence.

The question, of course, arises as to the nature of this condition of things. At first I was inclined to regard the case as being due to his excessive tobacco-smoking, as resembling, in fact, those cases described (a) by Sir Lauder Brunton, in which over-smoking is shown in sudden faintness. "The man falls as if he were shot." He considers that this symptom only occurs among those who smoke the better class tobaccos, and I am not sure if "best shag" comes under that category. Though tobacco is known to stimulate the vagus, and so to give rise to a slow pulse, yet, when it does affect the pulse at all, my belief is that some irregularity is always produced, as well as reduction of the rate. Now, in this case irregularity of the pulse has been most strikingly absent. In many respects the case resembles that curious symptom-complex known as "Stokes-Adams" disease. Thus there are:

1. The slow pulse specially characterised by being unaffected by exercise or diffusible stimulants.
2. Vertigo, which occurs as much in the recumbent as in the upright position.
3. Syncope lasting for a few seconds.
4. Slight epileptiform convulsions.

This is perhaps the most characteristic feature of the condition. In my case there were the two syncopal attacks in the hospital, during which twitchings of the limbs were observed; and as, according to Babcock, (b) the convulsive movements may be no more than a twitching of the mouth, they would naturally have escaped the notice of an unskilled observer, hence, I was never able to obtain any history of convulsive movements in the attacks while he was an out-patient. As an objection to this view, it may be urged that in my case the pulse was not appreciably diminished in rate during the syncopal attacks, as is usually the case in Stokes-Adams disease, but the very short duration of the attack made this point difficult of exact observation.

With regard to the rather sudden appearance of an apical systolic murmur, I do not feel prepared with any adequate explanation; it is well known that patients who have had a cardiac murmur during life have, after death, in Stokes-Adams disease, been found quite free from any cardiac lesion.

Stokes himself, however, believed that in these cases there was always fatty degeneration of the heart. While this view as to the pathology is held by some, others regard it as a pure neurosis, while in a few instances lesions of the vagus and cardiac plexus have been discovered *post-mortem*. The prognosis of Stokes-Adams disease is bad, death occurring suddenly in one of the syncopal attacks; the prognosis in my case would have, therefore, to be rather guarded, in spite of the apparent general improvement of the patient's condition.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

MEETING HELD FEBRUARY 24TH, 1905.

The President, DR. FREDERICK TAYLOR, in the Chair.

DR. J. H. BRYANT showed a case of Anæmia Splenica with marked Pigmentation and Clubbing of the Fingers. The man, æt. 48, temperate, who had never been abroad, had had in July, 1876, a severe fall, and was struck on the left side of his abdomen. In 1900 he suffered acute abdominal pain, and was told that he had an enlarged spleen. In January, 1894, a severe attack of abdominal pain was accompanied by hæmatemesis. He had a yellowish-brown complexion, his fingers were markedly clubbed; he said they had been so as long as he could remember; the spleen was enlarged and extended two inches below the umbilicus; there were numerous patches of dark brown pigmentation in the skin over the dorsum of the foot and front of the legs; the urine was normal; red blood corpuscles 4,350,000 per c.mm., hæmoglobin 70 per cent., colour index 0.8, white blood corpuscles 4,375 per c.mm.

DR. WILFRED HARRIS asked whether Dr. Bryant drew any distinction between cases of splenic anæmia presenting pigmentation and clubbing of the fingers, and those not presenting these symptoms.

DR. TAYLOR referred to a case of splenomegaly with hepatic cirrhosis and jaundice that he had shown before this Society some years ago. That case had pigmentation, large spleen, and clubbed fingers, so resembling the case now shown, save for the cirrhosis.

DR. WALTER SPENCER referred to the good result that had been obtained abroad after splenectomy in these cases. The operation was an easy one if no adhesions were present.

DR. PARKES WEBER thought that the primary lesion in this case was a vascular defect, as the pigmentation was clearly the result of cutaneous hæmorrhages. In some of these cases the enlargement of the spleen turned out to be due to thrombosis of its vessels.

DR. PHEAR did not consider splenic anæmia a suitable name for the case, as no anæmia was present.

DR. BRYANT, in reply, referred to Osler's recent monograph in which Banti's disease was shown to be a terminal stage of splenic anæmia. He did not advise splenectomy on account of the great tendency to hæmorrhages exhibited by the patient.

MR. EDRED M. CORNER showed a case of Dislocation of the Atlas from the Axis, with Fracture of the Anterior Arch of the Atlas. The man, æt. 21, had fallen off a horse upon his forehead. He "saw stars," but was able to mount and ride home. A fortnight later the patient's neck was found to be rigid, and he carried his head a little flexed and turned to the right. He had a difficulty in opening his mouth, also in articulation and in mastication, but not in swallowing. The left transverse process could be felt between the mastoid process and the angle of the jaw; as to the process on the right side the examining finger found in its place a depression, whilst at the back of the pharynx on the right side there was a prominence. A skiagraph showed the dislocation of the atlas from the axis on the right side, and also a fracture of the anterior arch of the atlas. The condition of the odontoid process was doubtful.

DR. PURVES STEWART showed a case of Narcolepsy and Hysterical Blindness. The man, æt. 22, previously healthy, had had an attack of influenza six weeks ago. A fortnight ago he complained of pain in the left side of the chest, but there were no abnormal physical signs, and he had insomnia for four or five nights. He was then given fifteen grains of sulphonal, and slept for nineteen hours continuously. Since then he had had attacks of sudden sleep, occurring at meals, during games, &c., lasting several hours at a time. Four days before admission he developed convulsive phenomena (opisthotonos, &c.) just before waking. Three days

before admission he awoke to find himself practically blind. He could now only distinguish light from darkness, and the gait was that of a blind man. He kept the eyes directed habitually straight forward. Optic discs, pupils, and cranial nerves normal. No headache nor vomiting. Urine normal.

Dr. ALEXANDER MORISON thought that hypnolepsy would be a better term in this case than narcolepsy. Some degree of cyanosis was usually associated with the condition, and they often terminated fatally.

Dr. PURVES STEWART, in reply, justified the term, which was invented by Charcot. The interesting part of the case was the blindness. This was not always present and differed from organic blindness in that the patient did not attempt to look in the direction of the person speaking to him, but kept his head fixed.

Mr. A. H. TUBBY showed a case three years after Muscle-grafting for Paralysis of the Left Upper Extremity. In June, 1901, the boy, then *æt.* 7, had had infantile spastic paralysis of the left upper extremity from birth. The forearm and hand were in the position of excessive pronation, with flexion at the elbow and wrist. The fingers were strongly flexed. The pronator radii teres was detached, then passed behind the radius and re-attached so as to act as a supinator. The palmaris longus and other flexor tendons at the wrist were divided. The patient had regained extension at the elbow, supination of the forearm, and flexion and extension of the fingers, especially when the humerus was fixed.

Dr. FARQUHAR BUZZARD did not think that there was any evidence that muscle-grafting had done any good, as the tenotomy might account for any improvement that had occurred. The child could even now only supinate to the mid-position, and this was brought about purely by the biceps.

Dr. WILFRED HARRIS asked whether massage had been tried before the operation. If it had only been used since, it may have been largely responsible for the improvement.

Mr. DOUGLAS DREW asked as to the state of the supinator brevis at the time of the operation.

Mr. TUBBY, in reply, claimed that great improvement had taken place on the original condition. The supinator brevis had not been examined.

Mr. WILLIAM TURNER showed a case of Primary Sore on the Eyelid of a Child. The girl, *æt.* 3, had been quite well until early in January, when, without obvious cause, a pimple formed on the margin of the right lower eyelid towards the outer side, and had since steadily enlarged. An enlargement of the glands below the jaw on the right side had been first noticed on February 11th, and there had since been a steady increase in size. The child had seemed ill since February 18th. It had been sleeping with its mother. The mother, *æt.* 29, had had several living children, two born alive, who died after a few weeks, and one miscarriage. She had been under treatment in August, 1904, for secondary lesions, mucous patches in the throat with enlarged glands, and an eruption on the hand.

Mr. CAMPBELL WILLIAMS pointed out that acquired syphilis was of worse import to a child than congenital syphilis, perhaps because the latter cases were armed with maternal antitoxins. In this case he advised inunction rather than internal medication. Extra-genital chancres were usually atypical.

Mr. TURNER, in reply, said that he intended to treat the case with Hydrarg. c. creta, but would use inunction if that failed.

Dr. J. G. SLADE showed a case of Lymphatic Leukæmia with Microscopic Specimens of the Blood, showing an enormously increased number of White Blood Corpuscles. The patient, a house painter, *æt.* 49, had been in hospital under Dr. Allchin. He had always been a teetotaller, without venereal history, and was a moderate smoker. He began to complain, in the autumn of 1902, of weakness and pains all over, and lumps in the neck were first noticed by his wife. In May, 1903, a doctor found lumps in the neck, axillæ, and groins, larger than they are now. He

improved under treatment, but before admission lost flesh, was short-winded, and his face became yellowish. He had had no bleeding nor diarrhoea, nor oedema of the ankles. He was found to have enlarged glands, supra-clavicular, axillary, and inguinal; they were soft, discrete, movable, and not tender. The liver extended two inches below the costal margin, the spleen was enlarged, extending two inches below the umbilicus, and the notch could be felt. His urine had a trace of albumin. Blood examination, February 21st, red corpuscles, 2,430,000; hæmoglobin, 24 per cent.; white corpuscles, 1,300,000; small lymphocytes, 96 per cent.; large hyaline corpuscles, 3 per cent.; polymorphic, 1 per cent.; of the polymorphic 5 corpuscles were finely granular to 1 coarsely granular; blood platelets scanty.

Dr. PHEAR pointed out that the polymorphonuclear cells, which composed 1 per cent. of the leucocytes, were relatively diminished, but absolutely these were increased nearly three-fold.

Dr. PARKES WEBER commented on the low colour index, 0.5, which was rare in leukæmia.

Dr. TAYLOR speculated on the date of onset of the leukæmia. Large glands had been present several months before the blood had been examined.

Dr. SLADE replied.

Mr. BATTLE showed a case of a man, *æt.* 37, who had swollen knee-joints. The swelling dated from an acute attack in the elbows, knees, and ankles three years ago. The diagnosis was doubtful.

Mr. CAMPBELL WILLIAMS thought that the case was of syphilitic origin, though gout, rheumatism and tubercle had to be considered.

Mr. DOUGLAS DREW showed a girl, *æt.* 7, showing Complete Restoration of Function after Arthrectomy of the Knee-joint. Arthrectomy was performed in September, 1904, for tuberculous synovitis, which had started after a fall two years before. The whole of the synovial membrane was studded with small tubercles. The sutures were removed a week after the operation, and five days later a daily movement of the joint was commenced. A month afterwards some adhesions, which limited movement, were broken down under an anæsthetic. All swelling subsided, and the child had been running about for some months with full movement.

Dr. DOUGLAS DREW also showed a Girl, after excision of the Navicular for Tuberculous Disease.

Mr. KELLOCK said that the result in the first case was so wonderful that he was forced to doubt the original diagnosis. The tibiæ were thickened and curved as in congenital syphilis. The appearance of the synovial membrane in syphilis might mimic tubercle closely.

Mr. DREW, in reply, had no hesitation in saying that the case was tuberculous. He found no evidence of syphilis. He was himself astonished at the result seeing that, not wishing to cut the crucial ligaments, he had left some tuberculous material behind. The disease was only in the superficial layers of the membrane. The good result was due to the chronicity of the lesion.

Mr. J. HUTCHINSON, jun., showed a case of Ossifying Sarcoma of the Fibula. The patient, a man, *æt.* 35, had observed the tumour during the last two years. It overlapped the tibia, and extended from a hand's-breadth below the knee to the lower third of the leg. The radiograph proved that it grew from the fibula alone, and that there was a large amount of bone towards its centre. It interfered but little with the muscles of the limb, but had caused a certain amount of pain. Pulsation in both anterior and posterior tibial arteries did not seem to be altered at the ankle. The patient had sustained no injury to the part and no other cause could be assigned for the development of the tumour.

Dr. EASTES pointed out that clinical examination seemed to show that the growths proceeded from the tibia, while the radiograph clearly proved that it came from the fibula.

Mr. KELLOCK did not think it made any difference

where the growth came from, as it had crept so far round the limb that amputation at the knee was necessary. He was surprised that Mr. Hutchinson intended only removing the fibula, and feared that the posterior tibial vessels and nerve would of necessity be injured.

Mr. DOUGLAS DREW quite agreed with Mr. Kellock as to the line of treatment. Even when early and high amputation was done in these cases, the prognosis was very bad, death invariably occurring in under a year.

ROYAL ACADEMY OF MEDICINE IN IRELAND. SECTION OF STATE MEDICINE.

MEETING HELD FRIDAY, FEBRUARY 10TH, 1905.

The President, SIR JOHN W. MOORE, in the Chair.

EARTH-TEMPERATURE AND DIARRHOEAL DISEASES IN DUBLIN DURING 1904.

THE PRESIDENT read a paper on this topic. Having quoted the late Dr. Edward Ballard's views on the relation between a critical temperature of 56° F. at four feet below the surface of the ground and an epidemic mortality from diarrhoeal diseases in late summer and early autumn, the author of the paper submitted and explained two diagrams showing a comparison between the death-curve from diarrhoeal diseases in the Dublin registration area during the summer and autumn of 1904, and the earth-temperature records from the Normal Climatological Station, which was established within the precincts of the University of Dublin by the Provost and Senior Fellows of Trinity College on January 1st, 1904. The diagrams show that in 1904 diarrhoeal mortality was trifling till the week ended August 6th—that is, the third week after the subsoil temperature at four feet had passed above 56° F. The mortality increased week by week, until 35 deaths from diarrhoeal diseases were registered in the week ended August 27th—that is, about 10 per cent. of all the deaths from those diseases (339) registered in the course of the whole year 1904. This maximum of mortality followed the maximum of warmth of the soil at four feet (58.5° F.) by an interval of just a fortnight. Such a coincidence is at least remarkable, and may be turned to practical account as a warning that diarrhoeal diseases are about to become rife whenever the earth thermometer at four feet rises to 56°.

Dr. KIRKPATRICK said that the chief interest and value of the observations was to give an indication of the onset of these attacks of summer diarrhoea in children to the authorities, who could then take precautionary measures, and give timely warning of its approach. This was possible, owing to the interval which elapsed between the rise of the earth-temperature to the critical line of 56° and the incidence of the diarrhoea. He did not think there was sufficient evidence to show that the rise of the temperature to the critical line and the summer diarrhoea were connected causally. It was more probable that the earth-temperature reached a certain height only during conditions when epidemic diarrhoea was liable to arise also, and there was probably an organism which could develop when the earth-temperature had been a sufficient height for a certain length of time. This was borne out by the fact that the mortality from summer diarrhoea was much less among breast-fed than bottle-fed children, and everyone knew the difficulty of giving bottle-fed children even moderately sterile food. There could be no doubt that this epidemic diarrhoea was started by the introduction of poisonous food into children, and it was probably caused by organisms capable of producing decomposition in foodstuffs, and not by any specific bacillus. He hoped that active measures would be taken next year to prevent the onset of summer diarrhoea, and warning given in time to take due precautions.

Dr. CRAIG was sure that Sir John W. Moore did not mean to convey that the earth-temperature alone caused this epidemic diarrhoea. It was only lately

that physicians had recognised that this very fatal affection was due to micro-organisms. He thought that the heightened temperature tended to increase putrefaction, and that flies had a great deal to do with carrying the infection. People who were careful with regard to their food were rarely affected with summer diarrhoea. He thought that children used often to be affected through the state of the bottles themselves.

Dr. M'VITTIE said he would like to have an explanation of the statement that diarrhoeal diseases were more markedly on the increase in those districts where the houses were closely built than where there was an excess of population. This would indicate that the earth-temperature could not be the main factor because a large portion of earth covered by closely-built houses could not rise to the same temperature as places where there was a lot of open space between the houses. Closely-built houses maintained a more equable earth-temperature in summer and winter. Therefore there must be a number of other factors in the causation of these diseases, such as increase of fruit supply, &c. Another factor was that young people in cities became exhausted at that time of year, and their capacities for mastering those diseases lowered. Small children played a lot in the sun, got into heats, and then got chilled.

Dr. LANGFORD SYMES thought that those who suggested that there was a multiple series of factors producing those diseases held the correct view. These diseases seemed to destroy more children than adults, and, perhaps, a milk diet accounted for that. We seemed to be more exempt from them in Ireland than in other places, such as New York, where the infant death-rate was much higher. The climate here seemed to minimise them, there being no great difference between the summer and winter temperatures in Dublin. The earth-temperature certainly seemed to have a great deal to do with the development of the organisms which caused the diseases and predicts their onset. As to food, it was found by Holt that this factor greatly influenced their onset among infants. The ground had recently been gone over again in America by bacteriologists, and they had come to the conclusion that not only the earth-temperature, but also food, had a good deal to say to their causation. Again, Holt had noticed in his series seven cases of breast-fed infants who had also got water from the tap without boiling, and the seven had died; therefore the diseases might be water-borne. Another factor was sanitation, and, indeed, these diseases used to be taken as a sanitary index. With regard to infection, light had been recently thrown on this question by Shiga in Japan, who had found a bacillus which gave the Widal and Pfeiffer reactions with blood serum, and which he considered to be the specific bacillus of the diseases. It was called the *Bacillus dysenteriae* of Shiga. Besides this bacillus there was also the Flexner-Harris type, which was found principally in the mucous portions of the stools, and in scrapings from the mucosa after death. An acid medium was necessary for their growth, and we knew that many children's foods developed acidity, which might account for their ready growth. A serum had been made from horses, and injected in these cases, but it had not proved to have much value. He thought that Dr. Craig had struck a good note in referring to flies, insects, &c., as a means of conveying serious infection.

Dr. MATSON asked Sir John William Moore if he thought the nature of the ground had anything to do with those diseases. He himself, whilst in a London hospital, had seen a severe epidemic and had gone from that to Hampshire, where a similar epidemic occurred. The soils in the two places were very different. The following year, whilst in Las Palmas, where the temperature was 80° to 85°, he asked a doctor there what his experience of those diseases was. He told him that he had never seen them in children nursed by their mothers, whilst there was a considerable amount of fatal diarrhoea among older children, who were liable to infection from fruit, garbage, &c.

Dr. WINTER said that Sir John spoke of a heavy rain-

fall seeming to have been followed by a decline in the death-rate. While in England, twelve years ago, he himself had had occasion to examine the reports on the Tees Valley epidemic of enteric fever, and a heavy rainfall there was followed by a great increase in the number of cases. If these two facts were correct, he would say that enteric was water-borne, and these diarrhoeal diseases were not water-borne, but were carried through the air contaminating the food.

Dr. NINIAN FALKNER said he would like to call attention to the nomenclature of these so-called diarrhoeal diseases. Some years ago, statisticians found a lot of cases returned as gastro-enteritis, enteritis, and mucocenteritis, and it soon became evident that these terms were loosely used. A special committee was appointed, the net result of whose labours was that these three divisions were all placed among the local diseases of the digestive system.

Sir JOHN WILLIAM MOORE, in replying to Dr. Kirkpatrick, said that last year the observations had been used to give warning of the onset of diarrhoeal diseases. He had been careful in his paper not to commit himself to saying that the earth-temperature was the absolute cause of these diseases, but said it was a remarkable coincidence. He agreed that various organisms might cause the diarrhoea. A very interesting point was, that the symptoms were referable to poisoning of the centres in the medulla oblongata. He also agreed with Dr. Craig as to the mischief caused by flies, and thought that this was very far-reaching. He believed that small-pox infection had often been carried by them. He could not quite agree with Dr. M'Vittie that the mere placing of houses over the soil would very materially interfere with the rise of the subsoil temperature. With regard to Dr. Symes' observations, he said that everyone agreed that food was of extreme importance. With regard to the nature of the soil he said that clayey soil always warmed up more slowly than gravel or sand, so that diarrhoeal diseases might be expected earlier in the latter case. With regard to what Dr. Winter had said, he thought that the mortality had been checked last year by heavy rains, this going in favour of contamination by dust or flies.

A short paper on "Sicily as a Winter Health Resort" was then communicated by Dr. PARLATO, of Palermo.

HARVEIAN SOCIETY OF LONDON.

MEETING HELD FEBRUARY 9TH, 1905.

Dr. G. A. SUTHERLAND read a paper on
LOBAR PNEUMONIA IN CHILDREN.

He referred to the valuable information to be obtained by a study of the child's expression and breathing. The expression of the face was much more placid in lobar pneumonia than in catarrhal pneumonia, owing to the obstruction conditions present in the latter. The breathing in lobar pneumonia was rapid, superficial, and often of inverted respiratory type. The increased movement of the *alæ nasi* usually consisted of an expiratory and not an inspiratory dilatation, and was due to forcible expiration. He reviewed the clinical symptoms of three leading types of pneumonia, the cerebral, the gastro-intestinal, and the renal, in which all through the disease the pulmonary condition might remain unsuspected. Renal cases might present as the leading symptom hæmaturia or general dropsy. The treatment in ordinary cases was practically that of a specific fever. Coughing, fever, sleeplessness and pain were symptoms which might call for treatment. As a rule the pre-critical stage was the period of greatest severity, and cardiac tonics and leeching were the best remedies at this time.

Dr. GUTHRIE thought that lobar pneumonia was better recognised now, being less fatal than bronchopneumonia. He thought the facies were anxious, not apathetic and placid—the breath being held on account of pain. He believed central pneumonia with distant tubular breathing occasionally occurred. He

remarked on pseudo-crises. Strychnine should be pushed where required.

Dr. JAMES TAYLOR also thought the expression was mostly anxious. Digitalis when given should be started early in the disease. Empyema was more common after lobar pneumonia than after the catarrhal form.

Dr. ALEX. MORISON thought the fever should be treated if high, and not allowed to run riot, as it affected the circulatory system. Ice to the head was soothing and a useful antipyretic. Bleeding was at times useful at the onset. He also thought strychnine was a drug that should be pushed when needed. Digitalis he did not use. Turpentine is useful when there is much secretion in the tubes.

Dr. CAUTLEY was accustomed to differentiate between children and infants in speaking of pneumonia in childhood. One should always remember the possibility of otitis media as a complication, often unaccompanied with pain. Bleeding in children was rarely necessary, and he doubted the advantage of using the ice-bag.

Dr. SUTHERLAND replied.

Mr. LAMING EVANS read a paper on

ANTERIOR METATARSALGIA.

with notes on seven cases. In reviewing the literature of the subject he drew attention to the fact that Morton and Bradford had described the disease in feet otherwise normal, whereas R. Jones had found twelve out of fifteen cases with flat-foot also; that Morton and Jones had resected in the majority of the cases, whereas Bradford, Gibney, and Poldthwait stated that the operation was never necessary. An analysis of these seven cases showed that the fourth metatarso-phalangeal joint was affected in all and the third in two cases. All the cases occurred in women, six in private and one in hospital practice, in this agreeing with all previous records. Neither injury, nor sudden onset, nor rupture of the transverse ligament were present. The longitudinal arch was depressed in three cases, and the transverse arch in three. The fashionable narrow pointed shoe was considered responsible for an aggravation of the mischief, if not the actual cause of it. Five of these cases had been dealt with by palliative measures, with partial relief of symptoms, and two by excision of the head and neck of the fourth metatarsal bone with complete removal of the pain, and with a sound functional foot, without any weakening. He advocated that palliative measures should be tried in the first instance, but if these failed, that removal of the head of the metatarsal bone should be performed with a good chance of curing the disease, and without fear of weakening the foot.

Mr. JACKSON CLARKE had not operated on these cases during the last five years. The general health should be improved and much attention paid to shoes. He advocated the use of steel plates in the boots, carefully made after taking a plaster mould or model of the foot. Metatarsalgia was often a symptom of flat-foot. Patients were often markedly irritable with this condition.

ULSTER MEDICAL SOCIETY.

MEETING HELD IN THE MEDICAL INSTITUTE, BELFAST, ON THURSDAY AFTERNOON, FEBRUARY 16TH.

The meeting was a new departure, consisting of a clinical demonstration of interesting cases, no papers or notes being read. The cases on the agenda paper numbered 34, but several more were brought, so that ample material for the demonstration was forthcoming. The attendance of members was large, including many country members, who cannot conveniently come to the evening meetings, and all agreed that the new departure was most successful, and should be repeated.

The PRESIDENT (Dr. William Calwell) showed (a) A case of Angio-neurotic Edema, and (b) Some Illustrations of Skin Diseases.

Professor LINDSAY showed a case of Acromegaly, with photographs.

Dr. ST. GEORGE showed (a) a case of Pernicious Anæmia, and (b) a case of Syphilitic Ataxia.

Professor Sir WILLIAM WHITLA showed (a) a case of

Lead Palsy, and (b) a case of Paralysis Agitans. The gait in the second case was most typical and interesting.

Dr. CECIL SHAW showed (a) a case of supposed Malignant Growth at the outer side of the eye in a boy *æt.* 5. The case came under his notice five weeks before, with a history of a conjunctival catarrh, following a supposed blow on the eye a fortnight earlier. The eye was examined under an anæsthetic, but nothing could be found except a slight purulent conjunctivitis, with granulation tissue at the outer canthus. In the last fortnight this had increased, and marked swelling at the outer side of the eye had arisen, apparently in the bone, rendering a diagnosis of malignant disease at least probable. (b) A case of Sudden Amaurosis after Influenza. Vision began to fail the second day of a slight attack of influenza in a healthy young man, *æt.* 20, and in three days was reduced to counting fingers at a foot in the right eye, and *nil* in the left. Taste was also lost, but recovered in a few days. There was no headache or vomiting, the discs were normal and the pupils dilated. The patient had been under observation just six days; no improvement had taken place, nor had any other symptoms shown themselves, and a provisional diagnosis of toxic amaurosis caused by influenza had been made.

Mr. A. B. MITCHELL showed five cases:—(a) A case of Tumour of the Upper Jaw. The tumour in this case was an epithelioma simulating an epulis. (b) A case of Club-Foot after operation. (c) A case of Necrosis of the Skull. The interest of this case lay in the fact that it was an extensive necrosis of tuberculous origin occurring in a patient, the subject of hereditary syphilis. (d) A case of Removal of both Pectorals. Removal of both pectorals had been carried out in this patient for a large carcinoma of the breast. Three weeks after operation, a very free range of movement was preserved. (e) A case for diagnosis.

Dr. JOHN McLEISH showed a Cerebral Case for diagnosis. The patient was an ex-soldier, a man of about 45, with a history of syphilis. His present illness began about three years ago, with headache, vomiting, and almost complete right hemiplegia. At the present time the hemiplegia is practically well, but he has complete double optic atrophy, apparently primary, occasional headache referred to the back of the head (not nearly so severe as formerly), occasional nausea, especially when suffering from constipation, and occasional convulsions of the Jacksonian epilepsy type, beginning in the right hand and extending up the arm. The probable diagnosis is a gumma about the hand motor area, or possibly an exostosis of syphilitic origin.

Dr. THOMAS HOUSTON showed a case of Acne of the Face treated by injections of sterilised staphylococci, after the method of Professor A. E. Wright. The affection had been fairly severe for a year, and now after three injections the face was almost clear.

Mr. ROBERT CAMPBELL showed eight cases. (a) A case of Congenital Deformity of Hand and Forearm, combined with Obstetrical Paralysis of the Face. The patient was a child of 13 months, in whom the left forearm and hand were imperfectly developed, the hand being flexed. The obstetrical paralysis of the face, which had no connection with the imperfect development, had persisted unchanged. (b) A case of large simple Meningocele successfully excised. (c) A Meningo-myelocele complicated with a nævoid lipoma, also excised. (d) A patient who had had a large Congenital Hairy Mole, covering half the forehead, the left temple, and the parotid region of the left cheek. It was completely excised, and immediate skin-grafting by Thiersch's method carried out. The result was very good. (e) A boy, *æt.* 3, who had been the subject of three abdominal sections in less than two years, two for intussusception and one for the radical cure of hernia. (f) A case from which a large Hydrencephalocele was excised six years ago. The tumour, which was one and a half times the size of the child's head, was formed by the posterior end of the right lateral ventricle. It was removed at the age of three weeks, and its removal necessitated the removal of the right occipital lobe.

The child is now six, and cannot walk without help. He can only say a few words, but can understand all that is said to him. There is hemi-atrophy of both discs. (g) A case of Deformity of the Elbow, resulting from a fracture of the humerus. The fracture involved the external condyle, with displacement downwards, producing marked gun-stock deformity when the arm was extended. (h) A case of Ankylosis of the Temporo-maxillary Joint. This occurred in a boy, *æt.* 8, as the result of a crush between two wagons. Attempts to remedy the condition by forcible separation with a gag failed, and Mr. Campbell had removed both condyles three weeks ago, with the result that the boy had now almost perfect restoration of movement.

Mr. JAMES CRAIG showed two similar cases of Imperfect Development of the Eyes, occurring in sisters. These children were aged about 10 and 8, and both had aniridia, unilateral in the elder and bilateral in the younger. There was as well an irregular nystagmus, with very defective vision. The children showed no sign of mental defect.

Dr. J. C. RANKIN showed (a) Two cases of Lupus treated by Röntgen Rays, and (b) Two cases of Lupus treated by Finsen Light.

Dr. J. R. DAVISON showed a curious skin case for diagnosis.

Dr. MCKISACK showed (a) a case of Locomotor Ataxy in a young subject, and (b) a case of Paralysis Agitans.

Mr. ANDREW FULLERTON showed (a) a case of Simple Ulcer of the Bladder, successfully treated by Suprapubic Cystotomy. (b) A boy with a testicle in the perinæum. (c) A case of Papillomatous Synovitis of both Knee-joints, successfully treated by partial erosion.

LIVERPOOL MEDICAL INSTITUTION. MEETING HELD FEBRUARY 16TH, 1905.

Dr. JAMES BARR, the President, in the Chair.

MR. RICHARD WILLIAMS exhibited and demonstrated the particular advantages of a modified eye speculum.

Drs. T. R. and E. E. GLYNN related a case of
INTERNAL HYDROCEPHALUS

in which the symptoms simulated those of intracranial tumour. The patient received a blow on the head in 1898, which caused temporary loss of consciousness. Gradually symptoms of cerebral tumour developed, and these symptoms continued until June, 1903, when clear fluid commenced to flow from the right nostril and very soon improvement set in, followed by complete recovery in the course of a few weeks.

Dr. A. G. GULLAN read notes of two cases of
ADDISON'S DISEASE,

in which he had administered suprarenal extract. In the first case, that of a young man, in whom the symptoms of the disease were well marked, 15 grains of the extract were given thrice daily, but with only temporary relief, the patient dying seven weeks later. At the *post-mortem* examination no signs of tubercle were found except in the suprarenal bodies, which were both enlarged and destroyed by caseous masses, evidently of a tuberculous nature. In the second case, that of a woman, the symptoms were less severe, and she had greatly benefited by taking 20 grains of the extract thrice daily.

Mr. DAMER HARRISSON opened a discussion on
THE UNION OF NERVES AFTER DIVISION.

He gave a short history of the subject—physiological and surgical. The more recent histological observations which support the theory of coalescence and the process of regeneration in the peripheral or of a divided nerve were described, together with the criticisms of Mott, Halliburton and Edmunds. On the physiological side he advanced the view that the weight of evidence was on the side of the outgrowth theory; and brought forward a series of observations made by himself and Professor Gotch, after division and suture of the sciatic nerve in the rabbit, which proved that sensation reflexes appeared first in the peripheral and nearest

the point of suture, and at later periods, at the more distant points in the peripheral end. With regard to the motor response, this appeared at an earlier date in proportion to the nearness of the division and suture to the muscles. These facts were difficult to explain by means of the coalescence theory, and strongly supported the outgrowth theory.

Dr. ROBERT KENNEDY said that from the clinical point of view there was a well-established observation, which the central theory of regeneration of nerves could not explain, namely, the early return of sensation after secondary suture of a divided nerve. Ranvier's view does not explain this rapid restoration, for in the first place unnaturally rapid growth of new nerve fibres from the central end would be required, as no sensation could be felt until the axis cylinders had reached the end organs. In the second place, there would be a difference of time in the reappearance of sensation accordingly as the section of the nerve was near or far removed from the end organs, which there is not. As regards suture of the nerve immediately after section, sensation takes much longer to appear, and this is what one would expect, as time is required for regeneration of the new fibres in the distal segment. When suture is performed at a time remote from section, the distal segment has had time to form its new nerve fibres. The only difficulty is to explain the very early passage of impulses across the plane of suture, but this is probably brought about by the junction of neurilemma cells newly formed from the central and peripheral ends, the gap being thus bridged, the impulses apparently having the power to pass along the protoplasm of such cells. The reason why motion recovers later than sensation is owing to the rapid degeneration of the muscles after nerve section, which degeneration must first be recovered from. From observations made in the past few years he was of opinion that muscular tissue never completely degenerates, although separated from the nerve centres for long periods. A series of microphotographs were shown illustrating his views of nerve regeneration in the distal segment as opposed to the recent explanation advanced by Langley and Anderson.

Professor SHERRINGTON said he favoured the peripheral rather than the central theory of nerve regeneration, and remarked that after removal of a spinal ganglion, delicate nerve fibres can be found in the portion of the root attached to the cord.

Dr. W. B. WARRINGTON called attention to certain alterations in the nerve cell which took place after section of its axome. In this condition, known as chromatolysis, the cells assume the embryological form in preparation for renewed activity. Chromatolysis occurs in nearly all the cells of the spinal ganglia when the section is made on the peripheral side, but not at all when the posterior root is divided. In the former case the nerve fibres regenerate, but not in the latter. Similarly after section of the anterior root, nearly all the cells of the corresponding segment in the vertebral horn undergo chromatolysis and ultimately repair; but after cutting off the incoming impulses by division of the posterior roots, and thus producing a permanent isolation, some of the cells of the anterior horn atrophy and undergo complete degeneration. It was submitted that these experiments furnish evidence of the important part taken by the cell in the regeneration of a nerve fibre.

Professor J. S. Macdonald and the President also took part in the discussion.

OTOLOGICAL SOCIETY OF THE UNITED KINGDOM.

MEETING HELD MONDAY, FEBRUARY 6TH, 1905.

DR. THOMAS BARR, President, in the Chair.

The Inaugural Address was delivered by the President, which we hope to publish in our next.

Discussion of Mr. Chas. Heath's paper on the RESTORATION OF HEARING AFTER REMOVAL OF THE DRUM AND OSSICLES BY A MODIFICATION OF THE

RADICAL MASTOID OPERATION FOR SUPPURATIVE EAR DISEASE.

Prof. URBAN PRITCHARD said that it was the experience of otologists that the complete post-aural operation in a large proportion of cases was followed by an improvement in the hearing. He, Prof. Pritchard, was afraid that Mr. Heath operated on many cases which would not be considered by most otologists to require operation. He thought the operation described was practically Stacke's operation. He thought it was a pity that the paper was published in the *Lancet* before the discussion on it took place.

Mr. MACLEOD YEARSLEY thought the only novel thing about the operation, which was really Stacke's, was the indiarubber head sheet. He did not think it was possible to ascertain the condition or extent of the antrum by means of bent probes introduced through a small opening, and ridiculed the idea that in 60 per cent. of the cases the whole of that cavity was situated in the pars petrosa. He did not think it necessary to interfere with the stapes, even if it were possible, as Mr. Heath stated, to snip off the crura.

Mr. CHICHELE NOURSE thought any suggestion which tended to shorten the after-treatment of the complete mastoid operation should be welcomed. He thought the real question at issue was whether Mr. Heath's procedure was a step in advance—the question of the selection of cases did not enter into the paper, though he might remind members that Dr. Dench had advocated operating on every case of suppurative otitis media. Mr. Nourse thought the modifications were matters of small detail rather than of principle—the stitching of the meatal flap, the use of the large tubes and spirit drops, all of which were improvements.

Dr. MILLIGAN said that Mr. Heath's paper started from false premisses, *viz.*, that bad results as regards hearing were obtained by the ordinary method of doing the mastoid operation. He thought it was the experience of every otologist that the ordinary operation resulted, in the great majority of cases, in a marked improvement in the hearing. The number of cases operated upon was rather staggering, especially for a throat hospital. In his experience, not more than 4 per cent. of the cases in an aural clinic required the complete operation. Dr. Milligan did not think it was possible to see the "fenestra" without removing a large part of the posterior wall of the meatus, and thought it unlikely that if the greater part of the mucosa were so diseased as to require removal, the portion around the fenestra would be healthy. He complained that no definite data had been supplied to members, as promised, concerning preliminary treatment and duration of the disease.

Mr. C. A. BALLANCE said he felt unable to discuss the paper without having attached to it details of two or three dozen consecutive cases. He did not think any English otologist should write such a paper without reference to the great work which had been done in Germany. With regard to the operation itself, he did not think any but the most limited and slightest form of disease could be removed or even exposed by it. It was claimed that the incision left no disfiguring scar, neither was there a disfiguring scar in the operation performed by him (Mr. Ballance) or his friends. The flap was described by Stacke in 1889; as to restoration of hearing Mr. Heath must be quite unaware of the results of the radical mastoid operation. He (Mr. Ballance) had examined twenty consecutive old cases last year, and in every one found an improvement in hearing, and in some a very remarkable improvement; but he did not claim that his results were exceptional. All his friends got practically the same result. He had no experience of narrowing of the meatus, nor of delayed healing except where it was impossible to remove the whole of the disease.

Mr. FRED. SPICER congratulated Mr. Heath on his results, such results showed that there was no justification for submitting patients to two operations; indeed,

until that evening, he had been under the impression that the grafting operation had long been given up. He himself owed Mr. Heath a debt of gratitude because since he had adopted his methods, the time during which his patients had been under treatment had been reduced by one-half. The question of the selection of cases was not dealt with in the paper.

Dr. H. MACNAUGHTON-JONES thought the question of the selection of cases for operation was of greater importance than the *technique* of the operation. He complained of the absence of trustworthy statistics which Mr. Heath had promised to provide, if possible. They knew nothing of the conditions which preceded the operation. He could not discuss the paper from an operative point of view, but he certainly could discuss it from the aspect of the experience of therapeutics in otology, and he could not conceive of such a condition of things as Mr. Heath had said existed, *i.e.*, that so great a proportion of cases needed operation.

(Mr. ARTHUR CHEATLE moved, and Mr. FAGGE seconded, that the meeting do proceed to the next item on the programme. As other gentlemen wished to speak, the motion was not adopted.)

Dr. PEGLER was sorry at the turn the whole discussion had taken. He asked whether Mr. Ballance would not grant that Mr. Heath took it for granted that members would be fully acquainted with the details of the Schwartz-Stacke operation, and in that way admit that it was not necessary in a short paper to allude to what those magnificent surgeons had done, and without whose work Mr. Heath would probably not be operating as he was? It would be more correct to speak of Mr. Heath's "methods" than of his "operation." He had been struck with the great care Mr. Heath took in the many details of the operation—particularly with the introduction of the rubber meat tube.

(A suggestion by Dr. JOBSON HORNE that the discussion should be adjourned until statistics had been supplied was not seconded.)

The PRESIDENT said it was to be regretted that Mr. Heath had not submitted to them precise scientific details as to the condition of the hearing before and after, the duration of treatment before, and the exact pathological condition present at the operations. Mr. Heath was no doubt an earnest man, anxious to do right; he might have been carried away by his enthusiasm and his paper had suffered from the lack of precise notes of the cases. Mr. Heath had shown some excellent results without packing, but his (the President's) experience was that judicious and careful packing was essential to get a permanently open epithelial-lined cavity.

Mr. CHARLES HEATH replied. The only statistics he could give them were as follows: Average duration of treatment before operation, 13 months; average duration of the disease, 15 years; percentage cases with improved hearing, 84 per cent. A great many patients were so pleased with the improvement in the hearing that they begged him to operate on the second ear when that was affected. His publication of the paper in the *Lancet* before the discussion was not a precedent. The after-treatment lasted from three weeks to three months. None of the cases were operated upon unless they had urgent symptoms or had been waiting six months for admission into hospital. He was not aware that so large a percentage of improved hearing had been obtained before. He did not think the skin grafting method lent itself to improvement in the hearing. The whole of the cavity, including the fenestra, could be seen in his cases without a speculum. He left the mucosa around the fenestra because any interference with it produced scarring and consequent damage to the hearing. He had referred to his operation as a modification of Stacke's. Mr. Ballance had said that he could not do the operation through the incision described. Many men had seen him do it and were satisfied that he had sufficient room. He went straight for the antrum and removed all the disease as was shown by the cases exhibited. He very much regretted not having the statistics asked for,

but he had now given all that were available. He regretted that members had not discussed the methods more, instead of other principles involved.

Dr. MILLIGAN then read notes of TWO CASES OF LABYRINTHINE SUPPURATIVE RECENTLY OPERATED ON, WITH SPECIAL REFERENCE TO THE PATH OF INFECTION.

CASE 1.—Patient, male, *æt.* 37. Left-sided suppurative middle-ear disease of twenty years' duration. Main symptoms: Deep-seated pain in the head, constant tinnitus, increasing deafness, and foetid discharge. Radical mastoid operation; exposure of outer labyrinthine wall; fistula in horizontal semicircular canal; sprouting granulations; enlargement of fistula; subsequent packing. Complete recovery so far as fresh symptoms concerned.

CASE 2.—Patient, male, *æt.* 46. Duration of disease over twenty years. Latterly severe headache, inability to work, constant tinnitus, intermittent attacks of vertigo, sickness, fairly well-marked facial paralysis, profuse foetid discharge from the left ear. Radical mastoid operation; large fistulous track leading through the fenestra ovalis into the vestibule, from which pus oozed; enlargement of the perforation, curetting, subsequent packing. Uninterrupted progress; recovery.

The cases were discussed by Mr. Hugh E. Jones, Dr. Whitehead, Prof. Urban Pritchard, and the President.

Dr. HERBERT TILLEY: Case of Acute Labyrinthine Suppuration in male patient, the subject of chronic otorrhoea. Symptoms: Severe temporal headache and deep-seated earache, slight dizziness, no tinnitus, temperature 102.2°, and general *malaise*. Radical mastoid operation, fistula discharging pus in external semicircular canal; the latter freely opened up and drained. Recovery.

Mr. L. LAWRENCE: Patient suffering from Chronic Non-Supplicative Middle-ear Disease, in whom a mere touching of either tympanic membrane produces marked and rapidly extending hyperæmia. The condition might be called "urticaria of the drum."

The case was discussed by Dr. Edward Law.

Mr. ARTHUR CHEATLE: A few notes on 250 Temporal Bones of all ages, sectioned vertically through the antrum and mastoid process.

Dr. W. H. KELSON: Notes of an Operation performed for Atresia of the Meatus. The patient suffered from deformity and atresia on the left side, and was shown at the December meeting.

Mr. ERNEST WAGGETT showed a patient, and Macro- and Microscopic Specimens and Drawings of a Case of Endothelioma of External Meatus. The tumour was observed in its early development in a man, *æt.* 43, undergoing treatment for another malady. After microscopical diagnosis the entire cartilaginous meatus was removed in April, 1903, and no recurrence has taken place.

The case was discussed by Mr. Arthur Cheate, Dr. Jobson Horne, and Prof. Pritchard, and the specimens were referred to the Pathological Committee.

Dr. PETERS exhibited a Modified Seigle's Magnifying Speculum which can be fitted to a Gruber's speculum.

Mr. RICHARD LAKE read short notes of Two Cases of Deafness secondary to Mumps, and exhibited specimens of Acute Suppurative Otitis in a child, and Chronic Suppurative Otitis in an adult.

Discussed by Mr. Arthur Cheate, Dr. Milligan, Mr. Yearsley, the President, and Mr. Hugh E. Jones.

Mr. HUNTER TOD read notes of a case of Hernia Cerebri et Cerebelli, the result of Acute Encephalitis. Question of treatment. Boy, *æt.* 10. Acute middle-ear symptoms in June, 1904. Paracentesis. Three weeks later admitted to hospital owing to general malaria and pyrexia, although otorrhoea had ceased and middle ear seemed nearly normal. Typhoid suspected at first. No tenderness, redness, nor swelling over mastoid process. Schwartz's operation. Pus in mastoid cells and granulations covering lateral sinus. Jugular vein ligated and lateral sinus freely opened; no thrombosis. Seven days later, owing to rigors,

drowsiness, and headache, cerebellum and temporoparietal lobe partially exposed and explored. Acute encephalitis found, with resulting hernia. Gradual recovery. Hearing now normal on affected side. Hernia covered with hard black crusts; pulsation at edges. Boy otherwise quite well.

Discussed by Dr. Milligan, Mr. Fagge, Mr. Waggett, Mr. Lake, and Dr. Horne.

Dr. MACNAUGHTON-JONES: (1) Drawing of Traumatic Perforation. Caused by blow of hand. The effect on the hearing will be described. (2) Exostosis of the Meatus.

Discussed by Dr. Horne, Dr. Edward Law, Prof. Pritchard, and Mr. Yearsley.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, February 26th, 1905.

HYPERTROPHY OF THE PROSTATE.

HYPERTROPHY of the prostate, says M. Legnen, is a veritable tumour, a kind of adenoma, similar to the adenomata which are found in the mammary gland. But this prostatic tumour, by reason of its position, produces very important modifications in the calibre of the urethra and the neck of the bladder. The two hypertrophied lateral lobes of the prostate produce a flattening of the urethral canal. It is this fact which induced a surgeon to invent a catheter flattened at the extremity, under the idea that it would slide in more easily. Such an instrument is not necessary, for the ordinary catheters succeed very well.

Besides this flattening, the canal is elongated and sometimes considerably so. The development of a median lobe constitutes another factor in the troubles provoked by hypertrophy of the gland. It pushes up the vesical wall, hence elevation of the neck of the bladder and the creation of a depression or *bas fond* in which the urine stagnates and becomes infected. Besides the elevation of the neck, the mucous membrane is thinned out so as to almost efface the wall. All these modifications necessitate a great effort on the part of the bladder, and finally its contractile power is weakened; retention and consequent infection are the result.

The three symptoms of prostatism are dysuria, acute retention, and incomplete retention with distension.

Dysuria.—The patient gets up at night and finds that urine is slow to come and the jet is weak. These accidents are more apparent at night and in the morning than during the day, by reason of the congested condition of the prostate. It can be observed also after fatigue or cold. In such cases the patient should not persist, but walk about a minute, when he will find the urine will come easily. In stricture of the urethra the patient should make an effort to overcome the obstacle. In hypertrophy of the prostate any effort is bad; it only increases the congestion, the cause of all the difficulty in micturition. This dysuria may last for years, it may remain stationary or lead to one of the two remaining complications.

Acute retention is found in men of about sixty years of age after a copious repast or a railway journey. The patient experiences pain, tension, and is unable to relieve himself. Catheterism puts an end to his sufferings and reduces the congestion at the same time. The organ, which was enormous, retracts the following day, as soon as the bladder has been evacuated, in astonishing proportions. This acute retention is not attended with immediately grave consequences. It is a warning of a malady that is commencing. Years may pass before another attack.

Incomplete retention with distension is otherwise grave, for it frequently passes unnoticed. The bladder becomes distended gradually, and no pain warns the patient of the danger. In a few months the bladder is capable of containing a quart or three pints of urine. The patient, instead of having retention, complains of incontinence. He micturates all the time. A patient, *æt.* 65, suffering from incontinence, is almost

certain to be suffering from incomplete retention with distension. He urinates a great quantity, four or five quarts daily from the ureters, and the kidneys are dilated. Signs of urinary intoxication appear: loss of appetite and strength, acute thirst, dry tongue, cachexia—all symptoms which have been more than once ascribed to cancer of the stomach, a regrettable error for the patient.

The only treatment of incomplete retention with distension consists in frequently emptying the *bas fond* of the bladder by catheterism, so as to prevent infection. Sometimes the placing of a catheter *à demeure* for a few days is necessary.

In acute retention, the patients show no cachectic symptoms. They are exposed, however, to hæmorrhage, through false passages created by the catheter from which infection may result.

OXYGEN WATER.

M. Gallois recommends oxygen water as a gastric stimulant in the dose of a teaspoonful in a glass of water. It excites the gastric secretion. In children oxygen water arrests diarrhoea. It can be given in ten drop doses in the milk. Novikoff employs the following prescription:—

Oxygen water, 12 vol., 1 drm.;

Syrup of oranges, $\frac{1}{2}$ oz.;

Water, 2½ ozs.

A tablespoonful every two hours.

Germany.

BERLIN, February 26th, 1905.

HR. MENZER, of Halle, has an article in the *Muench med. Woch.*, on

THE ANTISTREPTOCOCCUS SERUM TREATMENT OF ARTICULAR RHEUMATISM.

In his opinion this method of treatment is superior to all others, and for the following reasons: By means of it, disease that has become chronic may be cured, or at least improved; further, by its means acute rheumatism is more readily improved, and especially the chances of recovery in cases of endocarditis are better than by other methods; and, finally, recurrences are better warded off than by other methods, and that even in inveterate cases there is a possibility of considerable improvement.

At the Medical Society, Hr. F. Meyer gave an address on the

CLINICAL EMPLOYMENT OF STREPTOCOCCUS SERUM.

The speaker had exclusively used the serum prepared by himself from human streptococcus.

The action of the serum did not depend on its exciting the body cells to destroy the cocci, but it set free the antitoxin of the cocci and destroyed them in doing so. It had first to be ascertained what quantity was required for use, when was the most favourable time for its use, and lastly in what way was it best introduced into the system.

The clinical use of serum was two-fold—first, prophylactic, to prevent the occurrence of general sepsis when local disease was present, as in severe angina, erysipelas, scarlatina, endocarditis, and, secondly, remedial, when general sepsis was actually present. Generally in the first six hours there was a rise of temperature and symptoms of illness were observed; after two to twenty hours improvement set in and the best result was reached in twenty-four hours. Only seven cases of angina were considered; those with necrosing deposits or grave general symptoms. Both were seen to improve after injection. In septic diphtheria he recommended the injection of Behring's diphtheria serum, as well as his own streptococcus serum. He had the impression that complications such as nephritis were not so frequent with his serum, and that existing albuminuria passed off more readily. Erysipelas was only suitable for injection when it occurred in childhood or in operation cases, when it wandered and was accompanied by grave general symptoms. These cases improved, but one not infrequently saw

large vesicles form after injection; the local inflammation progressed, but without the pulse or temperature getting worse.

In scarlatina the serum had a favourable effect on the fever and the general symptoms, but he had not succeeded in cutting the disease short. His chief aim here was to prevent the outbreak of sepsis. Further observations were required on this point. He confirmed the observation of Bumm as regarded puerperal sepsis. It acted most favourably in cases of puerperal endometritis, quickly leading to the casting off of necrotic patches from the intra-uterine surface, without the onset of severe general symptoms. An injection should be made in cases of slight child-bed fever, and also after important or severe manipulations from which there was danger of infection.

The treatment was contraindicated where the centres of infection were large, and implicated vital organs. Thus in ulcerative endocarditis and disease of serous membranes; it was dangerous also in acute rheumatism and tuberculosis with high fever attributable to mixed infection. On the other hand, a favourable effect was often observed in suppurating carcinoma uteri, although, of course, the original disease was not affected by it.

The bye-effects of injection were neither frequent nor important, at most a local urticaria and a transient numbness in the leg into which the injection was made.

Great dilution of the serum was most advisable, even when large doses are given. More important still was a preliminary injection of physiological solution, and this should be repeated in twenty-four hours. In giving serum the essential point was the prevention of general sepsis. It was not to be expected that cases already going to the bad could be saved.

With his method of treatment, therefore, one should not delay until all other means had been exhausted, but it must be put to use in time.

Hr. H. Aronson denied that all bactericidal sera were alike: with streptococcus serum one was often in time after twenty-four hours; it required living cells to act on the living leucocytes, as Neufeld had shown.

He preferred serum obtained from animals, that from the human subject could not be tested. On the whole, he confirmed the clinical observation, but he did not agree with the contraindication fever. If the treatment was begun early small quantities of serum sufficed.

Hr. Heubner had experimented with serum in scarlatina, and on the assumption that sepsis was secondary had begun early. In spite of this, however, he had not been able to prevent sepsis; on the other hand, during recent periods both with and without the use of serum, he had seen cases recover after suppuration of the glands that he would formerly have looked upon as lost.

These experiences did not encourage further experiment in the case of scarlatina, but this did not show the valuelessness of serum in other forms of sepsis.

He did not look upon the so-called septic diphtheria as a mixed infection, but as a peculiarly severe form of bacillary diphtheria. Any effect from streptococcus serum here was not to be expected.

The discussion was adjourned.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, February 26th, 1905.

LARYNGEAL TUMOURS AND SUNSHINE.

SORGO showed several cases of laryngeal tubercle to the members of the Gesellschaft, which he had treated with perfect success by the rays of the sun. Since 1903, Kunwald had recorded fourteen such cases, which led him to adopt a similar method of treatment. The method is simple, only requiring the use of an ordinary toilet mirror and a throat lens, which the patient can easily be taught to manipulate himself. The toilet mirror is hung in a room where the sun strikes it best; the patient seats himself before it and with his throat mirror can reflect

the rays into the larynx where the tumour infiltration or ulceration is present. Under the influence of the rays the tuberculoma disappears in a very short time, not exceeding twenty applications. One of the cases he presented had suffered from tuberculous thickening of the left cord with tuberculous ulceration, which was now smooth and pliable, after twenty applications. His experience was that the infiltrated forms were more stubborn. He had recently accompanied the treatment by painting the mucous membrane affected with adrenalin in order to increase the specific effect of the rays as the blood seems to retard their action; hence by producing anæmia with the adrenalin the intensity of the rays on the deeper structures is increased. Unfortunately for this form of treatment weather does not permit of an unbroken course, hence the necessity of resorting to artificial light, which Finsen inaugurated and whose rays are probably more parallel with throat affections. In the discussion that followed Lang thought this form of treatment would be better adapted for lupus cases and might be tried. Exner recommended a silver mirror instead of the common glass used by Sorgo.

ESSENTIAL NEPHRITIC HÆMORRHAGE.

Zuckerkindl presented a male patient, æt. 17, who had suffered from what he terms essential nephritic hæmorrhage. According to the young man's history he had suffered for several months before presenting himself at hospital with hæmaturia, which apparently was induced or aggravated by exertion. Six weeks after admission the bleeding was continuous, and by the aid of the cystoscope it was discovered that the hæmorrhage was from the left kidney. To determine whether it was stone or tubercle it was resolved to operate in the lumbar region, using ether as the anæsthetic. After opening the capsule and examining the organ, neither of these morbid conditions were found present, but before closing the wound a small section of the kidney was taken for microscopic purposes. The whole was then closed; the hæmaturia immediately ceased; the patient rapidly recovered, and now is perfectly well. The histological examination under the microscope revealed a condition of glomerulitis proliferans which seems to have been the source of the nephritis hæmorrhagica.

Kapsamer, in the discussion that followed, said that he had performed nephrectomy in three similar cases with perfect recovery. Paltauf said that in such cases the abduction would probably give no indication of an inflammatory condition, and was inclined to disagree with its being a nephritis hæmorrhagica. Albrecht was of opinion that the changes were probably in the pyramid of the kidney or papillæ, which has recently been demonstrated histologically.

FIBROMA WITH SARCOMATOUS DEGENERATION.

Clairmont exhibited a female who had already been operated on three times for myomatous fibroma in the left labium majus. The tumour had now assumed large proportions, and it was his opinion that a radical operation was not likely to meet with any success.

LACTIC SECRETION IN PREGNANCY.

This subject was again reopened by Halban, who affirmed that the phenomenon of puerperal involution was gradual, and that the separation of the placenta immediately checked further physiological progress. He was firmly convinced that the placenta was the determining cause, because the embryo was often found to be dead months before the placenta separated and no lactic secretion discovered, but immediately the placenta is eliminated the milk secretion has been noted to be present. Mandl told us that one of his cases which he depended upon as proving the death of the fœtus as the cause was a mole. Now the separation of a mole is equal to the separating of the placenta, and would thus be proof against his own argument.

Kreidl again repeated his hypothesis, which was opposed to Mandl's, and assured the members that the separation of the placenta was the determining cause of the secretion. Popper said that all these experiments were against Czerny's hypothesis, that a

leucocyte condition was the cause of the colostrum. The opinion of an epithelial colostrum, such as the older authors believed in is now gaining ground.

Foges said that his own experiments were diametrically opposed to the uterus and the ovaries being the cause of the milk secretion. Biologically and mechanically from the distribution of the blood, as Schein has demonstrated, the separation of the placenta is a determining cause of the secretion.

Halban in reply, said he never believed the subject would have assumed such dimensions, but he was firmly persuaded that the death of the embryo or foetus was the real cause of the milk secretion and that the placenta had nothing to do with it.

The Operating Theatres.

ST. THOMAS'S HOSPITAL.

RUPTURED OVARIAN CYST WITH AN INGUINAL HERNIA.—Mr. BATTLE operated on a married woman, *æt.* 60, who had been sent to hospital by Dr. Hallam. She is said to have ruptured herself three years ago in opening a window; the hernia used to go back at night except within a year of admission, when it could be no longer reduced. Some nine months ago she began to get stout round the abdomen; this gradually increased for three months, when she was tapped by a doctor, who drew off, according to the patient's account, twelve quarts of fluid; the fluid soon re-accumulated, and four months afterwards she was again tapped, when about thirteen quarts were drawn off. On examination, when the patient was admitted, the abdomen was markedly swollen below the umbilicus and chiefly in the middle line. A somewhat tense, fluctuating tumour could be felt rising to a point just below the umbilicus, where it had a firm, rounded margin. There was resonance to about an inch below the umbilicus, but dulness in the flanks on dorsal decubitus. The patient had a large inguinal hernia on the right side which was easily reducible. Mr. Battle made an incision over the hernia, the sac was tapped, and a large quantity of pale yellow fluid escaped, after which the abdomen diminished considerably in size. An incision was next made in the middle line below the umbilicus about six inches in length; the large tumour found was brought to the surface and tapped; a thick, darkish-coloured fluid was drawn off, which at first flowed readily, but afterwards, becoming grumous and sticky, did not run through the cannula; but with the assistance of pressure round the tumour the contents were evacuated. After this the pedicle was ligatured and the cyst removed. There was a little difficulty in securing the vessels in the pelvis and a slight quantity of blood was lost. The other ovary was healthy. The tumour was a multilocular ovarian cyst. After the removal of the abdominal tumour, and the cleansing of the peritoneum and removal of all fluid from it, the operation for radical cure was performed by Mr. Battle on the hernia, whilst the house surgeon sutured the abdominal wall. Mr. Battle said that it was interesting to have the combination of the three conditions of ovarian tumour associated with much free fluid in the peritoneum and a distended hernial sac. The presence of the abdominal tumour was unsuspected at the time the first paracentesis abdominis was performed, and it was only after the abdomen had been emptied a second time that the medical man who sent the patient into the hospital discovered a tumour. The question was as to the nature of the fluid; was it ordinary ascitic fluid

or was it fluid which had arisen in consequence of irritation of the peritoneum, caused by the pressure of the tumour, or did it result from rupture of a cyst? The last was thought to be the most likely supposition, and it was thought also that the great distension of the hernial sac pointed to the presence of fluid of a higher specific gravity than ordinary ascitic fluid. At the operation a cyst in the posterior aspect of the main tumour was found to have an opening into it, and this was probably the source of the fluid. The intestines did not return very readily into the pelvis, being collapsed and compressed by the weight of the fluid, which had accumulated chiefly in the pelvis and pressed them upwards, so that a certain amount of air occupied the lower part of the abdomen, when the abdominal wall was closed, which should have been occupied by intestine. In a case of similar character some years ago, which had been described in the Medical Society's "Transactions" by Mr. Battle, the patient had double inguinal hernia, but in consequence of extensive heart disease it was not thought desirable to prolong the operation by doing radical cures of the herniæ; there also the patient had similar compression of intestines, and the pelvis and hernial sacs contained hardly anything but air at the conclusion of the operation, and for three weeks afterwards free air could be demonstrated to be still present, for pressure on the abdomen forced the air into one of the hernial sacs.

The patient made an uninterrupted recovery.

ITALIAN HOSPITAL.

OPERATION FOR THE REMOVAL OF AN ABDOMINAL CYST.—Mr. LENTHAL CHEATLE operated on a woman, *æt.* 45, who had been admitted under the care of Dr. Vincent Dickinson, suffering from a fixed cystic swelling which occupied the hypogastric and left iliac regions, but did not involve the pelvis. There was resonance over the front of it. There was a three years' history of the growth. The patient was a healthy-looking woman; there were no signs of intestinal obstruction. The abdomen was opened in the middle line. The cyst was found behind the sigmoid flexure and between the layers of its meso-colon the external layer of which was dissected off and the cyst enucleated. Its main vascular attachments came from an upward and inward direction, but were not traced to their source. The external layer of the meso-colon was then sewn up again after the enucleation of the cyst and the abdomen closed in the usual way. Mr. Cheatele said he had no idea as to the exact nature of the cyst. He suggested it might possibly be a cystic condition of some embryonic remnant. The cyst contained a fluid of brown colour, and microscopically tufts of papillomatous tissue could be seen. The wall of the cyst was covered by epithelium arranged in a slightly papillomatous manner, that is to say, here and there the epithelial lining was raised into little papillomata. Mr. Cheatele had never seen a cyst of this nature and in this region unconnected with the pelvis and its viscera; this particular cyst, he pointed out, did not pass below the true brim of the pelvis, and had it been allowed to grow it must have caused intestinal obstruction through pressing on the sigmoid flexure. The woman's ovaries, Fallopian tubes, and broad and round ligaments were normal. The cyst was the size of an adult head, contained about a pint and a half of fluid, but no hair.

The patient made an interrupted recovery.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MARCH 1, 1905.

THE LONDON HOSPITAL FUNDS, THE ORTHOPÆDIC HOSPITALS, AND SCOTCH QUALIFICATIONS.

THE attempts of the Metropolitan Sunday and the King Edward's Hospital Funds to guide, govern and direct the policy of the small hospitals have been on various occasions freely criticised in the columns of THE MEDICAL PRESS AND CIRCULAR. Those attempts have been, in our opinion, ill-advised, chiefly because they have been based on insufficient or wrong apprehension of the issues involved. So far as the orthopædic hospitals are concerned the principle of amalgamation has been insisted upon with apparent disregard of ultimate consequences. In this connection we feel it to be in the public interests unfortunate, to say the least of it, that the Chairman of the National Orthopædic before amalgamation should at the same time have occupied one of the most important honorary posts on one of the Hospital Funds concerned. The National Hospital has gathered £40,000 into its coffers by the sale of the site of the Royal Orthopædic in Oxford Street. That sale took place under the chairmanship of Mr. Harry Marks, M.P. It was opposed by a powerful minority and by two out of the three leading medical journals. That opposition forced up the purchase price by £12,000, and the contention of the opposition is that the valuable freehold site should never have been sold at all, that its value must go on rapidly increasing, and that the site should have been kept as a perpetual endowment in the hands of the charity. Lastly, they claimed that, if sold, its exact value should have been ascertained at public auction in Tokenhouse Yard. Now, the amalgamation scheme approved and advocated by the Funds permits Mr. Marks and his supporters to merge their financial mismanagement in the hotch-potch

of the common chest of the amalgamated hospitals. We claim that the public interests demand an impartial inquiry on the part of the Sunday and the King Edward's Funds before they put their final seal of approval upon the recent policy of the Royal Orthopædic Hospital. We submit that otherwise both these Funds lay themselves open to the suggestion that they may possibly have been made the catspaws of boards of management, the one desirous to hide financial mismanagement, and the other to secure a huge endowment with no particular regard to whether the money involved in the transaction had been acquired by prudent wisdom or by reckless folly. Surely, if the Funds take upon themselves the responsibility of advocating amalgamation of small hospitals, they cannot shrink from the further duty of informing themselves fully as to the issues that are involved in the process. We have in a previous issue (January 18th) referred to the condition imposed by the National Orthopædic excluding surgeons not holding the diploma of an English College. Hitherto Scotch diplomates had been justly and properly admitted to the staff of the Royal Orthopædic, and one of their most distinguished surgeons held that qualification. When amalgamation took place, however, the injustice of the rule at the National Orthopædic was, by private agreement, extended to the "Royal." It is true that one of the surgeons holding a Scotch diploma was permitted to enter the Amalgamated portals, but that was consented to only under the express understanding that, his term of office being nearly completed, his tenancy of the post would be short. Now we ask the Sunday and the King Edward's Funds if they, in advocating amalgamation of the orthopædic hospitals, were alive to the injustice they were inflicting, not only upon certain surgeons, but also upon whole colleges and nationalities. Were they not once again being made the catspaws of men who wished to secure a valuable monopoly in hospital appointments, regardless of the unfairness and injustice thereby inflicted upon holders of Scotch qualifications? As we have asked on former occasions, did the Funds know and not care, or did they not know and not care? Anyway, this monopoly of hospital appointments is unworthy and indefensible, and should be discountenanced by the Funds. What do the Funds propose to do in the case of the City Orthopædic, which they are now pressing to join the amalgamated hospitals? Two distinguished surgeons of the City hospital hold Scotch qualifications; are they to be compelled to abandon their staff appointments at the behest of the surgeons and the Committee of the National Orthopædic, or of the composite orthopædic body formed by the fusion of the Royal and the National Hospitals? We understand on good authority that the Funds have been so far stimulated by our criticisms as to inquire officially whether the National have excluded, and propose to exclude permanently, holders of Scotch qualifications from their

amalgamated medical staff. The public requires information as to this injustice which is being carried on in the charities they support. The Funds, which are supposed to guide the public and are now asserting their right to guide the hospitals, will do well to note the flowing tide of discontent that is gathering against this unjust monopoly of hospital appointments. In many ways we welcome the promise of some sort of central control of the medical charities of the Metropolis. It is well, however, that the movement should be conducted in the light of full information and publicity. We are proud to assume that under no other conditions would the countenance of two good and great members of the reigning house, King Edward and the Prince of Wales, be bestowed upon the Funds which they grace by their personal interest and patronage. But they may be reminded that the colleges of Scotland are Royal no less than those of England.

THE LEGALITY OF COMPANIES FORMED FOR MEDICAL AND DENTAL PRACTICE.

THE Council of the Irish branch of the British Dental Association have earned the sincere gratitude, not only of their professional brethren, but of all members of the medical profession throughout the United Kingdom, for the energy and perseverance with which they have attacked the unregistered practitioners in dental surgery who carry on a fraudulent and, we fear, lucrative trade under the mask of public companies. More than a year ago proceedings were instituted by the Irish branch against a company carrying on business under the name of Jaffé, Surgeon Dentists, Limited, to recover the penalties prescribed by the Dentists Act in the case of persons who, without being registered under the Act, assume a title thereby appropriated to duly qualified and registered dentists. The magistrates before whom the case came refused to convict, and the King's Bench Division decided upon a "case stated" that a corporation or public company was not a "person" within the contemplation of the Act, and might carry on trade under the prohibited titles with absolute impunity so far as any penal consequences were concerned. Undeterred by this reverse, the Council waited until one S. G. Rowell, who perceived the advantages to be gained by forming himself into a company similar to Jaffé, Limited, applied to the Registrar of Joint Stock Companies for a certificate of incorporation of "S. G. Rowell, Surgeon Dentist, Limited." The Board of Trade, to whose notice the facts of Jaffé's case had come, directed the Registrar to withhold for a time the certificate of incorporation. Rowell applied to the King's Bench for a mandamus to compel the Registrar to grant the certificate, and the Council of the Irish branch, by leave of the Court, appeared to show cause against the making of the order sought. The Lord Chief Baron, in a luminous judgment, in which Judges Andrews and Johnson concurred, held that the company had not been formed "for any lawful

purpose," as required by the Companies Acts, that its very name involved a false representation, and that its object was to deceive the public and to defraud registered dentists; the mandamus was accordingly refused, and "S. G. Rowell, Surgeon Dentist, Limited," perished in embryo. The Council had now succeeded, at least, in preventing the formation of any new fraudulent dental companies, but they were not satisfied with that result, and determined to attack those already in existence. Accordingly, proceedings were instituted in the name of the Attorney-General against "Mr. Appleton, Surgeon Dentist, Limited," a company carrying on business in Co. Down, for an injunction to restrain the company from advertising under or using a title calculated to deceive the public, and to compel the directors and shareholders to wind up the company. The case was heard by the Master of the Rolls on February 15th. No defence was filed by the company, which endeavoured to avoid costs by an abortive attempt to commit suicide before the motion for judgment came on for hearing, but two affidavits were put in by the directors, in which they tried to justify the formation of the company under the decision in Jaffé's case. The Master of the Rolls declined to yield to such an argument, and granted an injunction, with costs, not only against the company, but also against the directors, shareholders, and the signatories to the memorandum of association. In the course of this judgment—a perusal of which we commend to the directors and shareholders of similar concerns—he characterised the formation of the company as "an audacious fraud," expressed a clear opinion that the parties concerned in it might have been indicted for a criminal conspiracy, and held that the Attorney-General was fully justified, upon the highest grounds of public policy, in intervening to protect the public "whose health and, possibly, whose lives might be imperilled," by the imposition and fraudulent misrepresentation of unregistered quacks. The justice of his observations is demonstrated by a parliamentary return obtained during the last session on the motion of Sir John Tuke, which shows that no fewer than 89 companies have been registered in the United Kingdom "for dental practice" up to July, 1904, of which twenty-one carry on their trade in Ireland. We commend to the Council of the British Dental Association the example of the Irish branch, and suggest that the latter is deserving of more support and encouragement than it has hitherto received from the General Association in its campaign against illegal competition. We should be glad to see a united effort throughout the kingdom to stamp out a trade as dangerous to the public health as it is injurious to the regularly qualified members of the profession. That this question is of urgent moment to all our professional readers, and subscribers is demonstrated by the return alluded to above, from which it appears that, in addition to eighty-nine dental companies, a large number of companies have recently been formed "for the specific purpose of carrying on medical

practice," and so far as we can see, the decision of Sir Andrew Porter in the Attorney-General *v.* Appleton applies to every company which assumes the distinctive titles of registered medical or surgical practitioners, whether its alleged cures be effected by electricity, magnetism, hypnotism, or humbug, as much as to those which profess the practice of dentistry alone.

Notes on Current Topics.

The London and Counties Medical Protection Society.

THE London and Counties, although not the oldest of the medical defence associations, is to be congratulated on having led the way in the important matter of the accumulation of reserve funds. Last year, 1904, the balance of receipts over expenditure reached the handsome sum of £2,183. It is impossible to doubt that the stability of any organisation of the kind is enormously increased by the possession of a substantial endowment fund. To live, so to speak, from hand to mouth is always to incur a certain amount of risk from unlooked-for emergencies. The work of the Society has been characterised by the usual amount of thoroughness and energy. We are glad to note that the proceedings of Mr. Coroner Troutbeck have not escaped attention. The 1904 report says, regarding him, that "the liveliest indignation continues to be manifested by medical men practising in his district, and cases have been constantly brought under the notice of the Society in which Mr. Troutbeck departs from the recognised usage of coroners. A Committee, appointed by this Society, has been acting in conjunction with the British Medical Association, the Medical Defence Union, and the South-West London Medical Society, and has joined in a protest to the Lord Chancellor on the subject of Mr. Troutbeck's methods. A satisfactory solution of the difficulty has not yet been attained, and the question is receiving the close attention of the Society."

Medical Responsibility in Obstetrical Matters.

At the last meeting of the Central Midwives Board, Miss Wilson, a member of the Board, moved, and Dr. Cullingworth seconded, a resolution to the effect that the secretary of the Central Midwives Board should write to the Local Government Board and ask for a copy of all printed instructions and circulars issued by the Local Government Board dealing with the question of midwifery nurses. It then transpired that the reason Miss Wilson required this information was in order to obtain a circular issued by the Local Government Board, in which it was clearly laid down that the Board recognised the medical officers in infirmaries as responsible in regard to births, midwives being recognised and described as "midwifery nurses." We may be in error in our interpretation of this proposal, but it certainly conveys to us that Miss Wilson is desirous of trying to force the Local Government Board to alter

its regulations so as to make the midwife, and not the medical officer, responsible for the care of parturient women. We can quite understand Miss Wilson bringing forward such a proposition, but the only thing that makes us doubt the correctness of our interpretation of her remarks is that Dr. Cullingworth seconded it. What is the object of such a proposal, and does Miss Wilson seriously think that, supposing the impossible, supposing that her wishes were carried into effect, such an arrangement would conduce to the ends for which the Midwives Act was passed? Does she seriously think that the women trained by many of the teachers and in many of the institutions recognised by the Central Midwives Board are suitable persons to replace the medical practitioner in the care of parturient women in an institution. At the time of the passage of the Act it was indignantly denied by its supporters that it was brought forward with the object of creating an order of women to replace the medical practitioner; why, then, Miss Wilson's resolution? The "unfortunate" Central Midwives Board appears determined to pile the Ossa of stupidity on the Pelion of ignorance, but in this case it graciously gave permission to Miss Wilson to withdraw her resolution!

"Gouttes de Lait."

It is now some years since the philanthropic public in France established a large number of dépôts, under the names of *gouttes de lait*, where suitable artificial food might be distributed to infants and instruction given to nursing mothers as to the care of their young. The institutions became so popular that they have increased greatly in number, and have spread not only to the various cities of France, but to Brussels and other Belgian cities. From the start the movement received a good share of criticism from the medical profession, and with the growth of popularity among the people, the criticism has become more pronounced. As long as the main object of the "*gouttes de lait*" was the instruction of the mothers, there could be no opinion adverse to their utility, but, as the very name implies, their principal work is the distribution of artificial food. In a recent number of the *Journal Medical de Bruxelles* there is a strong criticism of the whole system by Dr. Marique. He cites as an example of the work done at the dépôt the fact that at one, of the mothers who attended only 2½ per cent. were suckling their children. He further points out that the establishment of these institutions has diverted funds from much more important and useful charities. Moreover, better results would be obtained if, instead of giving milk to the babies, money were spent in enabling the mothers to stay from work sufficiently long to suckle the children themselves. An instance is quoted of the result of the action of an employer of labour in Dornach in Alsace many years ago. This gentleman insisted on female employes remaining from work for at least six weeks after confinement, and he

continued to pay them as if they were working ; infant mortality fell from 40 to 25 per cent. The defence of the "*gouttes de lait*," as given in the same journal by Dr. Lernst, appears to be that the mothers will not suckle their children at any rate, and that therefore it is better that the infants should be provided with suitable artificial food. There is doubtless some scope for institutions of the sort, but there is the greatest need for care in their management. Anything which encourages mothers to substitute artificial for natural feeding is a danger to the vitality of the race.

Oysters and Sewage.

AN interesting series of experiments has just been carried out by Dr. Klein, at the instance of the Fishmongers' Company, with a view to ascertaining the condition and appearance of shell-fish contaminated with intestinal organisms. Oysters, cockles, and mussels were used, and their behaviour examined both when directly infected artificially with *Bacillus typhosus*, and also when kept for twenty-four hours in infected sea-water. Dr. Klein was able to show that in the case of oysters the bacilli were readily taken up into the organs of the molluscs under both sets of conditions, but that if the oysters were clean at starting they rapidly rid themselves of the micro-organisms when placed in fresh sea-water that was frequently changed. On the other hand, the clearing process was found to be much slower if the oysters were kept for any length of time in a dry state before being put into clean water. All the oysters taken from polluted sources were much more difficult to cleanse than those that were clean at the outset, and this process was again further prolonged if they were kept away from sea-water before the cleansing process was finished. Mussels took up the bacilli rapidly, and rid themselves of them fairly quickly when placed in sea-water ; but cockles, though they eagerly absorbed the organisms, took a long time to disembarass themselves of them. It must be remembered, however, that interesting as these experiments are, all experiments are open to fallacies, especially when all the accompanying conditions cannot be reproduced, and it will not do for merchants to fatten their oysters in polluted waters, and then place them for a few days in sea-water to clean themselves. There can be no positive safety in any process short of keeping oysters and other shell-fish in absolutely irreproachable water throughout their whole existence.

The Orthopædic Hospital of Ireland.

AN interesting function took place last week in Dublin, when the new premises of the Orthopædic Hospital were opened by the Lord Lieutenant and Countess Dudley. It is only something over twenty years since the Orthopædic Hospital was first started in very modest premises on the quays near Messrs. Guinness and Co.'s brewery. After some years in these quarters a move was made to the more central situation of Great Brunswick

Street, and now still larger premises having been required, the hospital has been again moved to Upper Merrion Street. It has there acquired an excellent and commodious house, which should afford every convenience for the carrying on of its work. During the whole course of its life, one of its founders, Mr. R. L. Swan, has been upon the staff of the hospital, and it is a matter for congratulation to him and his colleagues that the institution in whose small beginnings he took part a quarter of a century ago has now become housed in premises more suitable for modern surgical requirements.

The Prospect of Drought.

SOME justifiable anxiety is being felt at the present moment in many parts of the country as to the water prospects of the year. Last year was a dry one in England, only 20 inches as opposed to 24 inches of rain on the Continent having fallen, and much of this was evaporated quickly by the heat of the sun. So far this year things have been quite as bad, the rainfall in London being only about half the normal. If this state of things continues a serious situation may be created, for if there be not plenty of rain before the end of March we shall have to wait some five or six months before any considerable quantity can soak into the ground to supply wells and streams. Many local authorities in the North and in the Midlands are feeling disturbed at the prospect before them, and in Bath already the question of limiting the water supply is under discussion. London, Manchester, and the big towns which have practically unlimited resources to draw upon will probably not be affected perceptibly, but places that depend on spring and well water will be placed in an invidious position. It is hardly necessary to point out the grave menace to health that any curtailment of the water supply over large areas of the country is likely to entail, for water is intimately related to every aspect of personal and public hygiene. Moreover, dry years are invariably unhealthy years, in which diarrhoea and typhoid are rife, and apt to exact a high complement of victims. Although it may be better for umbrella-makers than for milliners, we must all hope for rain unless we wish the undertaker to have an exceptionally prosperous season.

The Effect of Anti-Vaccination.

If anti-vaccinationists were people who could learn from experience, then the present condition of the Union of Dewsbury would be an object-lesson of value to the country. As it is, it is merely a disgrace to our civilisation. Dewsbury has always been notorious for its anti-vaccinationist prejudices, and like Leicester and Gloucester, of similar repute, it has now suffered for them. Moreover, the Dewsbury Guardians not only declined to take the necessary steps to prevent an invasion by small-pox, but even when small-pox was present, they refused to attempt to

limit its spread either by the vaccination of the unaffected or the isolation of the stricken. The Local Government Board Report by Dr. Wheaton, recently issued, discloses an appalling condition of affairs. The Dewsbury Union contains, in addition to the borough of Dewsbury, the six urban districts of Thornhill, Ravensthorpe, Liversedge, Soot Hill Upper, Soot Hill Lower, and Ossett. In none of these, except in Dewsbury itself, was there at the beginning of last year any hospital provision for small-pox. Of the Dewsbury Hospital, Dr. Wheaton reports that it had not been put in proper repair, its windows were broken, heaps of refuse lay around it, and the wards were overcrowded, dirty, and ill-smelling. There was, moreover, undue incidence of the disease within a quarter of a mile of the hospital. Even up to last September, when about 600 cases of small-pox had occurred during the year, no provision for vaccination had been made. In Ravensthorpe, there being no hospital accommodation, small-pox patients were treated in their own homes. Nurses were not provided, and in some homes those who were convalescent had to nurse those who were still sick. In one house a convalescent girl of fourteen had the care of three younger children still in the acute stage. In the same house there was one unvaccinated child, and the father even then declined to permit vaccination. Even the men employed by the Urban Council to watch the infected houses and maintain isolation were not vaccinated, and many of them sickened. During the year 1904 there were in all 1,302 cases of small-pox in the Union of Dewsbury. Yet no one has been hanged.

Training of Nurses.

A MEETING was held on Wednesday last, at 20 Hanover Square, to protest against the Board of Trade licence being granted to the Incorporated Society for Promoting the Higher Education and Training of Nurses. The gathering was convened by the Matron's Council and the Society for the State Registration of Nurses, and was presided over by Lady Helen Munro Fergusson. A good many of the leaders of the nursing profession were present, and the speeches made were emphatic in condemnation of the proposed body as exponents of nursing and hospital opinion. It was pointed out that of the signatories to the memorandum of the projected association only Mr. Cosmo Bonsor had any knowledge of hospital administration, whilst of nursing questions in particular no single one had any special experience. The attempt to gain by a side wind an advantage that had been denied those who sailed ahead met with universal disapprobation, and on votes being taken on the resolution condemning the proposal, there were found to be no dissentients. In the face of this decision the Board of Trade are likely to be chary in consenting to the licence, and rightly so. We dealt with the subject ourselves in a recent issue, and we pointed out at that time the absurdity of the plan as put forward,

for it was proposed to fill the seats of the Council that was to control the education and examinations of nurses with nurses, leaving only two representatives of the medical profession. The Society for the State Registration of Nurses must, however, be very obtuse to the signs of the times if they imagine after their experiences of last session that a Bill embodying their proposal is likely to receive Parliamentary sanction in the near future. The same may be said of any plan that seeks to render nurses independent of medical men, and give them a colourable sanction to practise their profession as other than a subordinate one.

Pneumonia in America.

It is a striking feature of the death returns of the large American cities that pneumonia should hold so prominent a position, and the fact that it does so is giving much uneasiness to the rulers of the States. In Philadelphia pneumonia heads the list of deaths from all causes, and last year accounted for 3,360 deaths out of a total of 25,972. This contrasts markedly with the tuberculosis deaths, which numbered 3,107, and with 2,289 from the next highest cause—heart disease. In New York the prevalence of pneumonia amounts almost to the dignity of an epidemic, and the hospital resources are being somewhat severely taxed to deal with patients. In the meantime the Pneumonia Commission of the Board of Health is endeavouring to trace the origin of this unhappy state of things, and it hopes by next summer to have completed the programme of investigations that it has laid out for itself. The Commission has twenty men at work in different cities and laboratories, all pursuing independent lines of research from the clinical, preventive, and pathological points of view. The bulk of the pathological work is being carried out in the Bellevue Hospital Laboratory, a new building lately fitted up at considerable expense, and placed under the charge of Dr. Norris, who for many years assisted Dr. Prudden, pathologist to the Colleges of Physicians and Surgeons. It is greatly to be hoped that the clue to the alarming increase in pneumonia may be forthcoming, for it is not unnatural that the authorities should view with concern the rise in the pneumonia deaths from 7 per cent. to 17 per cent. in the course of twenty years. At the present moment, as we have said, pneumonia produces an even greater fatality among the population than does tuberculosis.

Medical Advice in Lay Papers.

THE question as to how far it is good taste and how far it is ethically correct for medical men to write on technical subjects in lay papers is one that is constantly cropping up, and we have our attention frequently called to border-line articles, and even to some that are over the border. It is, however, generally conceded that it is not permissible for medical men to advise and prescribe for patients in the columns of the ordinary press.

and we think that the General Medical Council would take a severe view of the case of writers who regularly contribute answers to correspondents on medical subjects, were the anonymity under which they usually shelter themselves unveiled. What, then, are we to think of a medical man who, under his own name and with his qualification appended, advises correspondents under the thinly-disguised plea of "Diet and Training"? In the March number of *C. B. Fry's Magazine* that lies before us—a healthy-toned publication, and one devoted to sports and physical culture—we find an article by a medical man whose name is associated with a certain class of popular literature, dealing with various matters under the heading mentioned above. The writer is gaining a certain *clientele* of correspondents, and to these he offers advice on subjects connected with the maintenance of "condition" from the medical point of view. In the particular number in question—whatever may be thought of the rest—there are two answers to correspondents which we think deserve careful attention. The first advises a gentleman who suffers from constipation to use Lucca oil with his daily diet, to massage the abdomen with castor oil, and if an aperient is needed not to take salines except in hot weather. The other is in reply to "Reader," who suffers from a sprained *tendo achilles* (*sic*), and this gentleman is asked if he has tried a Martin's rubber bandage. We submit to our readers the question as to how far such blind prescribing is in accordance with the traditions of the profession?

"Pathological Delirium."

It is a well-known axiom of British law that a plea of drunkenness is no excuse for crime committed by a person in a state of intoxication. Many a time the attempt has been made to override that position. Not long ago an Irish judge in a notorious case accepted a plea of the kind in question in extenuation of a most serious crime. The ingenuity of the lawyers in our own country, however, has never yet attained so sublime a height as that reached in a recent trial at Bundenburg. A large landowner of the district was accused of attempting to murder his steward by firing at him with a revolver in the course of a quarrel. Defendant's counsel pleaded that the prisoner was not responsible for his act, as he had been drinking, and several authorities on psychiatry declared him to be suffering from "pathological delirium," in consequence of free indulgence in intoxicants. The prisoner was thereupon promptly acquitted, and German law became enriched by a precedent that, without casting any great slur upon the national character, is likely to become extremely popular in the beer-drinking Fatherland. Were a drunken man held to be not criminally responsible in the United Kingdom, a large proportion of crime would go unpunished, including murder and many of the most serious offences against the person. It

would be a sorry day for society were the doctrine of "pathological delirium" to become established in British law. It appears to be really a hybrid kind of permissive class legislation, to be used on special occasions.

Myoidema.

A PECULIAR form of muscular contraction occurring in connection with diseases of the chest was first described by Dr. William Stokes, of Dublin, in 1830. Sixteen years later, Dowler, of New York, observed the same phenomenon in the cadaver. The term "myotatic irritability" was applied by Lawson Tait, in 1876, to the contraction of muscle fibres when percussed. Small, transient, local swellings, with a well-defined border, and elevated above the surrounding skin, may appear sometimes, the condition being then spoken of as "myoidema." Dr. H. L. Shively, (a) of New York, has summarised the literature upon the subject, and it may be at once noted that this curious muscular phenomenon does not only occur in phthisis, but in several wasting diseases. The pectoralis major is the muscle most usually affected, while the sign is hardly ever seen in the lower extremities. An attempt was made by Rudolph Schmidt to explain the occurrence of myoidema in pulmonary tuberculosis on the grounds of the anatomical relationship of the apex of the lung to the nerves of the brachial plexus. Its value as a clinical sign of early phthisis has many times been discussed, and very opposite views regarding it have been expressed. Dr. Samuel West found that myoidema was present in 3 out of 275 general medical and surgical cases. Dr. Shively has examined 750 consecutive cases of tuberculosis of the lungs with a view to ascertaining whether any form of myotatic irritability was at all frequent. The sign was present in 703 instances. Of 196 cases of incipient phthisis, myoidema was only absent in 18. It is not always constant, however, even in the same patient. When properly sought for, myoidema can never be overlooked, and although it cannot be absolutely regarded as having any real pathognomonic value, yet its occurrence in conjunction with other symptoms may be of some assistance in the diagnosis of early phthisis.

Governesses' Insanity.

THE altered system of modern education, the earlier age at which most children are packed off to school, combined with the growing refusal on the part of parents to employ uncertificated instructresses, are responsible for the increasing difficulty experienced by the individual who seeks to make a living by private teaching. A glance at the advertisement columns of the daily papers is sufficient to show that 50 per cent. more is required of governesses nowadays than was the case twenty years ago. They are expected to be thoroughly conversant with at least two modern languages, to be accomplished pianists and voice

(a) *New York Medical Journal*, January 14th, 1905.

trainers, to understand elementary science—physiology, most probably, excepted—to be well up in the classics, and to excel with the pencil and brush. In addition to these items, they must also be willing to supervise home-work, including pianoforte practice, and to throw themselves heart and soul into the various games and recreations of their young charges. A highly-educated woman may, perhaps, fulfil all or chief of these modest requirements, but unless she happens to possess a diploma of some sort she will have little chance in securing a good berth. This straining after certificates which is often undertaken when the proper work of the day is over, together with the worry experienced by the insecurity of their position, are among the chief predisposing causes of mental unsoundness as met with in these individuals as a class. So large, indeed, is the percentage of female private teachers amongst the patients of asylums that Dr. Savage has recently classified the disease as "governesses' insanity." Many of these hapless ladies have had to resort to teaching as a result of sudden ill-fortune, perhaps at an age when they can no longer adapt themselves quickly to new surroundings. The old-fashioned style of teaching may have some advantages, but it is not suited to the needs of the present day.

Surgeon-General Evatt and the Royal Colleges of Physicians and Surgeons of Ireland.

SIR THOMAS MYLES, in delivering a presidential address before the annual meeting of the Leinster branch of the British Medical Association made a full and explicit reply to the extraordinary charges brought by Surgeon-General Evatt against the Irish Colleges. Sir Thomas Myles referred to the ignorance displayed of the functions of the Colleges as nothing short of colossal; he described the limitations that hedged in their actions and dwelt on the many occasions on which the Colleges had striven to assist the officers of the Poor-law Medical Service, and to push forward the work of reform. Sir Thomas considered that the most extraordinary part of an extraordinary document was the reference to the position of the Irish Medical Association, and the manner in which it was to terrorise the Colleges. We are glad to notice that the Editor of the *Journal* of the Irish Medical Association stated that Surgeon-General Evatt's report had not been adopted by the Association, and that so far as he knew it would never be adopted, as a resolution had been passed by the Committee of Council recommending the Council to reject it altogether. This is a wise course to adopt, so far as that part of the report which deals with the Royal Colleges is concerned; but we should like, in the interests of the Irish Medical Association, that Surgeon-General Evatt's criticisms on the present management of the affairs of the Irish Medical Association should see daylight. We know that in this direction a radical reform is necessary, and it would be of value to

know what the General recommends, even if his recommendations in this case also are fatuous.

PERSONAL.

THE new Orthopædic Hospital of Ireland was opened by His Excellency Earl Dudley, when a very large company assembled to receive him and the Countess of Dudley. The hospital has now been established in Upper Merrion Street, a fine house having been secured and admirably fitted up for the special work.

A PAVILION for light and electric treatment has been opened at the Cardiff Infirmary. Through the generosity of Mrs. W. H. Martin, the building comprises an X-ray room, high-frequency sinusoidal room, Finsen lamp room, photographic and dark rooms, and a dressing and waiting room.

MR. PAUL WATERHOUSE has been unanimously appointed by Sir Donald Currie's Donation Committee architect to carry out the erection of the School of Advanced Medical Studies, students' house, and the nurses' home in connection with University College Hospital.

DR. W. A. MACKAY and Dr. Ian Macdonald, two Scottish practitioners in Huelva, Andalusia, Spain, have been elected honorary members of the Academy of Medicine and Surgery of Seville.

DR. WILLIAM OSLER, in bidding farewell to Johns Hopkins University, where he resigns the professorship of medicine on leaving for Oxford, advocated frequent changes of professors for their own good and that of their universities.

THE Transvaal Medical Council has elected Dr. W. F. Davies, of Johannesburg, as its first president. Dr. Davies is the son of Dr. Ebenezer Davies, Swansea, medical officer of health for Swansea.

THE council of University College, London, have appointed Dr. A. R. Cushny, of the University of Michigan, United States of America, to the Chair of Pharmacology and Materia Medica.

ON receiving from Professor F. T. Roberts his resignation of the Holme Professorship of Clinical Medicine and his physicianship at University College Hospital, the council adopted the following resolution: "That the council, in accepting with much regret the resignation of Professor F. T. Roberts of his offices of Holme Professor of Medicine and Clinical Medicine and physician to the hospital, desire to place on record their high appreciation of the services he has rendered to the college and hospital during his long connection with them, and of the distinction he has conferred upon the chair he has held."

PRINCE FRANCIS OF TECK presided on the 23rd inst at the annual Court of Governors of Middlesex Hospital, which was held in the board-room at the hospital.

DR. B. BARNETT, Assistant Medical Officer of Health, Hong Kong, is leaving that Colony to take up duty as Assistant Inspector of Hospitals in Egypt. Dr. Barnett, before proceeding to Hong Kong, in 1903, was Assistant Medical Registrar of St. George's Hospital, London.

THE President of the Royal College of Physicians of Ireland, Dr. W. J. Smyly, will entertain the Fellows of the College at a banquet in the College Hall on Saturday next, March 4th. The Lord Lieutenant has signified his intention of honouring the dinner by his presence.

AMONG those on whom the Senatus of the University of St. Andrews has resolved to confer the honorary

degree of LL.D. at the graduation ceremony this month, is Dr. Geo. A. Gibson, Edinburgh, author of "Diseases of the Heart and Aorta," and other well-known books.

THE managers of the Edinburgh Royal Infirmary have filled up the medical registrarship rendered vacant by the untimely death of Dr. Lockhart Gillespie, who had occupied the position for twelve years, by appointing Dr. A. Dingwall Fordyce, F.R.C.P.Ed., from among four applicants for the post.

ALEXANDER CRUM BROWN, M.D.Edin., D.Sc.Lond., F.R.S., Professor of Chemistry in the University of Edinburgh, a position which he has held since 1869; and Sir William Whittla, M.D., R.U.I., L.R.C.P., and S. Edin., Professor of Materia Medica and Therapeutics, Queen's College, Belfast, are among those upon whom the Senate of Glasgow University at its meeting on February 16th, resolved to confer the honorary degree of Doctor of Laws (LL.D.).

DR. DONALD MACKINTOSH will read a paper on "The Control of Hospital Expenditure with Efficiency" before the Hospitals Association at Charing Cross Hospital on Friday, March 3rd, at 8 o'clock. Tickets from the Hon. Secretary, the Hospital Building, 28, Southampton Street, Strand, W.C.

THE Gold Medal, founded by the late Sir Gilbert Blane, Bart., to be given biennially has been awarded by the Medical Director General of the Navy, and the Presidents of the Royal College of Physicians and the Royal College of Surgeons, to Surgeon S. T. Reid, R.N., for his "Journal" of H.M.S. *Vestal*, 1901-2, and to Surgeon R. W. G. Stewart, M.B., R.N., for his "Journals" of H.M. Ships *Latona* and *Thames*, 1903.

Special Correspondence.

[FROM OUR OWN CORRESPONDENTS.]

EDINBURGH.

ANNUAL DINNER OF THE ROYAL MEDICAL SOCIETY.—Professor Ronald Ross, C.B., F.R.S., was the guest of the evening at the President's Annual Dinner, which was held in the Hall of the Society on February 14th. About eighty were present, the guests including the Lord Provost, the Lord Justice Clerk, the Bishop of Edinburgh, the Presidents of the two Royal Colleges, and several members of the Senatus Academicus. A most successful and enjoyable evening was passed, Dr. Fletcher, Senior President, who was in the chair, proposing Professor Ross's health in felicitous terms, while the latter after replying, gave the toast of "The Royal Medical Society," to which Dr. Campbell Geddes responded. "The Sister Professions" was given by Dr. G. A. Gilson, and replied to by the Bishop of Edinburgh, and the Lord Justice Clerk.

PHYSICAL CONDITION OF SCHOOL CHILDREN IN DUNDEE.—Under the auspices of the Dundee Social Union an investigation was made during last summer of the physical condition of a section of the people. The inquiry was conducted in four board schools, one voluntary school, and one private academy; over 1,000 children were examined in these institutions. The following are a few of the facts elicited in the inquiry:—In elementary and board schools the physique of the children is defective, as regards both weight and height, when compared with Sir Francis Galton's averages, and with the average for the Harris Academy, Dundee. For example, the average weight of a boy of thirteen is 9 lb. below Galton's average, and that of an elementary school girl of twelve is 9 lb. below the average of the Harris Academy for the same age. The lengths and weight of 498 babies born in the Maternity Hospital, belonging to the same class as the poorer children in elementary schools, give an average weight less than, and an average height greater than Sir Francis Galton's figures. Dr. Templeman, Medical

Officer of Health, in his introductory medical report calls attention to the deficient weight of the poorer children, and states that their dietary does not include sufficient of the special elements necessary for growth, much of the parents' earnings being wasted on foods of low nutritive value, but which to them have the great advantage of requiring little or no preparation. A remarkable state of affairs was found in connection with the vision of the children, no less than one third of those examined suffering from defects so great as to interfere with their power of receiving instruction by ordinary school methods. Assuming the same proportion to prevail throughout the Dundee schools it means that nearly 7,000 children are seriously handicapped in the educational race, and at least 600 are in the position of running the risk of serious structural changes in the eyes. As a whole the nutrition of the boys was bad; the only bone disease found was rickets; the teeth show great evidences of neglect. Dr. Emily Thompson, reporting on the physique of the girls, notes that the condition of the heart was in many cases, specially from eleven to thirteen years, unsatisfactory, with signs of weakness and flabbiness from underfeeding and over-exertion. The whole report is well worthy of perusal.

SMALL-POX has again re-appeared in the neighbourhood of Edinburgh, four cases having been intimated during the past ten days in Leith. As the Burgh of Leith was very thoroughly re-vaccinated last year, thanks to the enterprise of the Town Council in offering free vaccination and a bonus of half-a-crown to all who submitted to the operation, it is unlikely that the disease will spread to any extent.

GLASGOW.

THE PROGRESS OF SURGERY.—At the meeting of the Glasgow Southern Medical Society, held on Thursday last, 24th ult., Prof. H. E. Clark, after expressing his great appreciation of the high honour conferred upon him by his election to the office of President of the Society, delivered an address on the progress of surgery, during the last thirty-four years, representing as they do the years of his professional life. He referred to the rapid tendency there had been to specialism in surgery and the growth of confidence in surgical methods. In the year 1870 the number of operations performed in the Royal Infirmary, the only general hospital then existing in the city, were 470, whereas in the year 1903, over 6,300 operations were performed in the Royal Western, and Victoria Infirmaries, exclusive of the operations performed in such special hospitals as the Samaritan and others. The rate of mortality in the Royal Infirmary in 1870 was 5·8, in the year 1903 it was 8·7; this considerable increase was to be explained on the ground that there were now a much larger number of serious surgical cases in the wards of general hospitals, compared with what there were in 1870. In the Royal Infirmary the rate of mortality was slightly below what it was in the Western or Victoria Infirmaries. Mr. Clark proceeded to sketch briefly and succinctly the operations now performed on the various organs of the body, brain, kidney, liver, stomach, peritoneum, etc. The presence of albuminuria is no longer, he held, an objection to the performance of any operation. The rapid advances in bacteriology were next passed in rapid review, and the valuable assistance rendered by the bacteriologist to the surgeon was readily acknowledged. In the Royal Infirmary the bedding was constantly being tested in the laboratory and when it was found septic was, in some very bad cases, destroyed, and in others subjected to disinfection by boiling, etc., before being again used. In this way many troublesome forms of dermatitis were now avoided which were at one time prevalent. A case was mentioned where a man entered the hospital with a badly swollen lip. The house-surgeon, discovered on examination the anthrax bacillus, and at once sent for Mr. Clark, who immediately operated, and so saved the man's life. In the experience of Mr. Clark the treatment by means of anti-toxins had been disappointing. The Rontgen Rays had proved most valuable in-surgical.

work, and their possibilities in the future, both in surgical and medical cases, it was quite impossible to estimate at present. A highly interesting and instructive address was brought to a close by the demonstration of several peculiarly interesting cases, including that of a young man, who was shown, and from whom the left arm including the scapula, and a portion of the clavicle were removed for a sarcomatous growth. Another case was that of a railway porter who got stabbed in the thigh, and where on account of profuse hæmorrhage the profunda femoris artery had to be ligatured; the hæmorrhage recurring, the femoral wasted and again it became necessary to ligature the common iliac artery through the lumbar muscles by means of an incision from below the ribs and along the crest of the ilium. The man made an excellent recovery. The ex-President of the Society, Dr. James Hamilton, in moving a hearty vote of thanks to Professor Clark for his admirable address, expressed the hope that it would be printed.

BELFAST.

The New High Sheriff.—Dr. Henry O'Neill, B.L., J.P., was last week sworn in as High Sheriff of the city of Belfast, and celebrated the occasion in a manner worthy of imitation by giving donations as follows:—To the Royal Victoria Hospital, £50; to the Mater Infirmorum Hospital, £10; to the Forster Green Hospital for Consumption and Diseases of the Chest, £5; to the Home for the Blind, £5; to the Maternity Hospital, £5; to the Day Nurseries, £5; to the Society for Providing Nurses for the Sick Poor, £5; to the Samaritan Hospital, £5; to the Presbyterian Orphan Society, £5; to the Protestant Orphan Society, £5; and to the Domestic Mission to the Poor, £5.

Prospective Legacy to the Forster Green Hospital.—It is said that the late Mr. R. W. Murray, of Belfast, has left a sum of over £120,000, the life interest of which goes to his widow, and at her decease the sum will be divided equally between the Forster Green Hospital for Consumption and the London Missionary Society.

Belfast Maternity Hospital.—The one hundred and eleventh annual meeting of this hospital was held last week, and was the first in the new building, which was opened in November. In spite of the interruption caused in the work by the removal from the old hospital to the new, 297 patients were admitted during the year, and 291 attended in their own homes. A serious outbreak of German measles occurred in the spring, and proved fatal to two patients. There was one fatal case of acute mania, and five other deaths were all in-patients moribund on admission. Ten nurses were trained, and received their diplomas.

Belfast Samaritan Hospital.—The annual meeting of this institution was held last week, but the medical report presented at it does not give many details of the work, as is natural. The patients treated in the extern department numbered 435, and in the intern department 134, of whom 118 required surgical operations. There were seven deaths.

Small-pox has reappeared in Belfast, some three or four cases having been notified during the past week.

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

THE LINCOLN EPIDEMIC.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.
SIR,—My attention has been drawn to the leading article in your issue of the 22nd inst., on the epidemic at Lincoln, and the means to employ to assure a supply of uncontaminated water to the citizens. You mention the "Salvator" (Vaillard-Dennarde's system) sterilising apparatus. Now, I happen to be much interested in the operation of that most useful appliance and have seen it at work in France, where it renders important service in many towns and institutions where the water supply—as so frequently happens in

Continental towns—is drawn from polluted sources. It is the only method I know of that will instantly produce indefinite quantities of cool potable water, sterilized in the only manner that will render dangerous water innocuous, by the use of great heat for a definite period. I am astonished the Lincolnians do not set up half a dozen of the machines in their town in places readily accessible, so that all those families who choose to use the water for drinking and cooking might ensure immunity from the scourge. From personal experience I can testify that the apparatus has been found to answer all requirements where it has been used in France. From a practical point of view Lincoln could have the apparatus brought over and set up within a week. In other words, within ten days the citizens of Lincoln could be drinking clean water. There is no other way yet devised by the wit of man in which that desirable end could be accomplished.

I am, Sir, yours truly,

VIATOR.

Hastings, February 26th, 1905.

OXONIENSIS!

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Oxford may be wise in having chosen as its Professor of Medicine a man who holds the view expressed by Dr. Osler, that after the age of forty men are worth little or nothing.

It looks rather as if Dr. Osler's views were correct if we may judge by the Oxford School of Medicine, and perhaps the University has chosen well. It is only to be hoped that Dr. Osler does not take the view that his life is finished, and that as he can be of no use in America he had better come over to Oxford and retire from active life. Oxford won't gain much if he does.

I am, sir, yours truly,

R. L.

STATE REGISTRATION OF NURSES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Referring to an article in your issue of Feb. 15th, I beg to point out that you have fallen into a grave error in assuming that the application to the Board of Trade, to incorporate a Society for promoting the Higher Education and Training of Nurses, has been made by the promoters of the Bill for the State Registration of Trained Nurses. On the contrary, the subscribers to the petition to the Board of Trade are seven well-known philanthropic financiers of the City of London, and the general body of nurses, as well as the members of the Society for State Registration have not been consulted and strongly oppose such a measure.

I am, Sir, yours truly,

AN ADVOCATE FOR STATE REGISTRATION.

February 20th, 1905.

[We are aware that the Society for the State Registration of Nurses is opposed to the issue of the proposed licence, as "An Advocate of State Registration" will see in reading our editorial columns this week. There are, however, other parties interested in the question besides the official society, and it was to these we referred. While no one can object to the higher education of nurses in the abstract, our own opinion on the constitution of the projected body was strongly expressed in the article our correspondent mentions.—Ed.]

Obituary.

S. THOMSON, M.D., D.Sc., OF GLASGOW.

THE profession in Glasgow has sustained a serious loss, and the citizens have lost an accomplished physician, through the too premature death of Dr. Thomson. He was only forty-eight years of age. He had been laid aside from active professional work for five or six months from granular kidney disease. Some improvement in his condition followed the first two or three months' rest, when the hope was cherished that he might be

spared to resume his professional work as family physician, consultant and teacher, but it was decreed otherwise. A *post mortem* examination revealed an aneurism of the aorta. Dr. Thomson graduated B. Sc. in 1880 and M.B. in 1882. In 1897 he graduated M.D. with honours and Bellahoustan Gold Medal, and D.Sc. in 1901. As assistant to Dr. James Finlayson he was closely identified with the teaching of clinical medicine in the wards of the Western Infirmary. In the year 1899 he was appointed to the Chair of Medicine in Anderson's College. He was generally recognised as a most successful teacher, his success being largely due to his painstaking methods in imparting to the large number of students in his classes the true essentials of medicine. For many years he gave much of his time to the teaching of the nurses in the Western Infirmary, by all of whom he was held in the highest regard and esteem. Always a close student of medicine himself, he was always in complete sympathy with his students in their desire to acquire a knowledge of their profession. By students, the whole of the medical profession in the city, and the citizens generally his loss is deeply mourned, as well as by a sorrowing widow.

J. HAMLLEN-WILLIAMS, M.R.C.S., L.R.C.P.LON., J.P.

WE regret to record the death of Dr. Hamlen-Williams, J.P., who for many years resided at Pontypridd, where he took a prominent position as a district councillor and holder of other public posts. He had had a successful career at the Middlesex Hospital, but he did not practise, preferring the enjoyments of a country life. The deceased's original name was Theophilus Richard Hamlen, but after the death of his uncle he assumed the name of Hamlen-Williams.

LT.-COL. E. DENHAM TOMLINSON, A.M.D.

WE note at Folkestone, in his sixty-ninth year, the death of Lieutenant-Colonel Edward Denham Tomlinson, A.M.D. (retired), and late of the York and Lancaster Regiment. He entered the army in 1860 as assistant surgeon, served in the New Zealand war, and was present at the capture of the redoubt of Katikara, and of the Pahs at Manutahi, and the destruction of Pahs and villages in the neighbourhood of Warea. He retired in 1880.

HORACE VAVASOUR SANDFORD, L.R.C.P.LOND.

MR. H. V. SANDFORD who died on February 5th, at the age of seventy-eight years, was one of the first medical officers of health to be appointed to a combined sanitary district, having been elected medical officer of health of the City of Hereford in 1874. In 1899, owing to failing health he resigned all his appointments. His reports were of the utmost value in the young days of public health work and were printed from the first. His death removes one of the pioneers of public health science.

SAMUEL HOLLINGSWORTH AGAR,
L.R.C.P.IREL., L.R.C.S.IREL.

THE death of Mr. Samuel Hollingsworth Agar, at Henley-in-Arden, Birmingham, on Feb. 11th, has removed a useful member of the profession in which he was well-known and much respected. Mr. Agar was in his seventy-fourth year. He was a native of county Wicklow and after taking his L.R.C.S.I., went to Henley-in-Arden in 1854. After a time, giving up general practice, he devoted his attention to the care of the insane, and became proprietor of a large private asylum—Glendossill, Henley-in-Arden—and his conduct of this establishment and his care and attention to the patients obtained him a wide reputation. Mr. Agar was a man of much public spirit and a member of the Warwickshire county council and a justice of the peace for the county. Mr. Agar leaves two sons, one of whom is a member of the medical profession.

ALEXANDER CRAWFORD, M.B., C.M.GLAS.

WE much regret to announce the death of Dr. Crawford, of Burdett Road, Stepney, London. At the outbreak of typhus fever in the East End he was called to attend one of the sufferers from that complaint. Soon afterwards he was attacked with illness, supposed to be influenza, and was admitted to the London Hospital, where he shortly afterwards died. As the cause of death was in doubt an inquest was held, but the *post-mortem* examination revealed no further facts. The Medical Officer of Health for Stepney, Dr. D. L. Thomas, inclines strongly to the opinion that the cause of death was typhus fever. In any case the sympathy of medical men will be with a professional brother, who has fallen in the front of the battle.

ON Wednesday, March 15th, at 7.30 p.m., the anniversary dinner of the Medical Society of London will be held at the Whitehall Rooms of the Hotel Métropole. Communications with regard to the dinner should be addressed to the honorary secretaries at 11 Chandos Street, W.

A SOCIETY for the study of questions of social medicine and hygiene and medical statistics was formally constituted in Berlin on February 16th, at a meeting of a large number of medical practitioners, political economists and sociologists. Professor Mayer, of the Imperial Statistical Bureau, Dr. Dietrich, of the Russian Cultus-Ministry, and Professor Lassar were elected Presidents.

THE Court of the Worshipful Company of Fishmongers has granted a sum of £1,000 towards the funds necessary for the incorporation of University College in the University of London. By this grant the amount still required to complete the funds necessary for incorporation is reduced to £17,000, a total of £183,000 having now been raised for this purpose. The Bill for the transfer of the College to the University was approved at the annual general meeting of the College on February 22nd.

Literature.

SHAW-MACKENZIE ON HYPODERMIC MEDICATION IN THE TREATMENT OF INOPERABLE CANCER.(a)

THE chemico-biological theory of the etiology of cancer is one which all who are interested in this fell disease will do well to follow up. Indeed, it may not be long before some startling developments will be evolved in this regard, judging from the scientific hold which the theory is beginning to acquire. The whole matter simply teems with interest; it offers an entirely new field of investigation and research in the endeavour to elucidate what cancer is, and in view of the lamentable failure of the parasitic theory of the disease, one can only hope that in this new field of research tangible results will be obtained which will go far towards robbing cancer of its horrors. That there is at least a reasonable hope of the possibility of this is proved by the results recorded by the author in this pamphlet. The method of hypodermic injection in the treatment of cancer is, of course, not new. But it is undoubtedly remarkable that chian turpentine when employed in this form should have yielded the gratifying results which the author's cases show. This would seem to indicate that the late Mr. Clay of Birmingham was probably right in his estimation of the value of chian turpentine in the treatment of cancer, but wrong in the mode by which he administered the drug. In the second part of his pamphlet the author deals with the hypodermic methods of treat-

(a) "Some Methods of Hypodermic Medication in the Treatment of Inoperable Cancer." By John A. Shaw-Mackenzie, M.D. Lond. London: Baillière, Tindall and Cox. 1904. 1s. net.

ment practised by Mr. Webb, of Melbourne. The hypodermic solution upon which the latter relies is one prepared with soap, more euphemistically described as oleate of sodium. Notes of some cases are given, all of which unmistakably show that hypodermic injections of a soap solution not only remove some of the worst features of the disease, namely, pain and fœtor, but even seem to have the power of arresting its progress. Precisely how chian turpentine and the soap solution act in this connection is, of course, still a matter of conjecture. But herein is concerned the chemico-biological theory of the origin of cancer. Mr. Webb holds that the first lesion in carcinoma is "crystallisation of cholesterol from the living cell, which may be caused either by local injury or chemical change in the cholesterol, as is affected by soot or by some change in the liver secretion." Dr. Shaw-Mackenzie points out that oil of turpentine is a solvent of cholesterol, and it is claimed by Mr. Webb that the same is true of soap; thus it may be by this action that the good effects of these two preparations in cancer are brought about. We have read this pamphlet with much interest, and can therefore cordially recommend its perusal, more particularly by reason of the important issues which it opens out, as well as upon the ground that it deals with facts which should be known to the profession generally.

MACNAUGHTON-JONES ON DISEASES OF WOMEN. (a)

The ninth edition of Dr. Macnaughton-Jones's most popular and valuable work will be sure of a warm welcome not only from the students and practitioners for whom it is intended, but also from all gynaecologists. The present edition appears for the first time in Messrs. Bailliere, Tindall and Cox's well-known "University Series," to which it constitutes a valuable addition. It has been practically rewritten, and a large number of beautifully coloured and plain plates and other illustrations in the text have been added.

The general system and arrangement of the book is similar to those of former editions, and is so well-known as not to call for criticism. We are sorry, however, that the author still adheres to his former plan, and that the diseases of the vagina and vulva find their place in one of the last chapters of the book. Such an arrangement is an inversion of the usual order of things and does not appear to us to be suitable.

There is a very excellent description of atmocausis and zestocausis, but there are two plates shown which are apt to prove misleading. Both of them show "Uterus and adnexa removed by atmocausis." This is surely a printer's slip for "after atmocausis." This, however, is a minor blemish. To criticise, however, in detail a book which has reached its ninth edition and become a recognised standard authority, would, indeed, be superfluous, and we need only heartily congratulate Dr. Macnaughton-Jones and his publishers on the present edition of what we have always considered to be one of the best epitomes of gynaecology in the English language.

YEAR-BOOK OF PHARMACY. (b)

The present volume of this excellent year-book is of more than ordinary interest, both for what it omits to mention in the progress of chemical knowledge and for what it contains. The space at the disposal of

(a) "Practical Manual of Diseases of Women and Uterine Therapeutics for Students and Practitioners." By H. Macnaughton-Jones, M.D., M.Ch., F.R.C.S., formerly University Professor of Midwifery and Diseases of Women and Children in the Royal University of Ireland, and Examiner in the same subjects; ex-President of the British Gynaecological Society. Ninth Edition. "University Series." London: Bailliere, Tindall, and Cox. 1904. Pp. xxv. and 1,044. With 137 Plates and 653 Illustrations in the text. Price 21s.

(b) "Year-Book of Pharmacy, comprising Abstracts of Papers contributed to British and Foreign Medical Journals from July 1st, 1903, to June 30th, 1904; with the Transactions of the British Pharmaceutical Conference at the Forty-first Annual Meeting, held at Sheffield, August, 1904." Edited by J. Braithwaite, R. Seville Park, M.A., and Edmund White, B.Sc., F.I.C. London: J. and A. Churchill. 1904.

the editors did not admit of reference to radium, hence no mention is made of the researches of the Curies, Dewar, and others. On the other hand, an excellent summary of the investigations of Charpentier and Becquerel into the nature of Blondlot's N-rays. As might be expected, arsenic and its compounds occupy considerable attention. A very valuable contribution is the summary of the papers of the Paris Municipal Laboratory on the analytical chemistry of brandy and its substitutes. Wobbe's tests for the purity of ether should interest anaesthetists. New, or newly applied, remedies are described with considerable fulness, so that both the pharmaceutical chemist and the medical practitioner have their wants provided for. We think there is no better year-book for the physicians' desk than that of pharmacy, and we cannot imagine how anyone interested in the progress of therapeutics and therapeutic remedies could be without it.

NEW BOOKS AND NEW EDITIONS.

The following have been received since the publication of our last list:—

- FELIX ALCAN.
Les Nerfs du Cœur, Anatomie et Physiologie. Par Blie De Cyon. Pp. 252.
- Le Traitement de l'Hypertrophie sénile de la Prostate. Par Dr. A. Guepin. Pp. 141. Price 2fr. 50.
- BAILLIÈRE, TINDALL AND COX (London).
A Dictionary of New Medical Terms. By George M. Gould, A.M., M.D. Pp. 571. Price 21s. net.
- Cancer and its Treatment. By A. W. Mayo Robson, D.Sc., F.R.C.S. Eng. Pp. 69.—Price 7s. 6d. net.
- Ship Surgeon's Pocket-Book and Medical Officer's Log. By W. E. Dawson. Pp. 61. Price 2s. 6d. net.
- Lateral Curvature of the Spine and Pelvic Deviations. By Richard Barwell, F.R.C.S. (sixth edition). Illustrated. Pp. 103. Price 3s. net.
- The Diagnosis and Modern Treatment of Pulmonary Consumption. By Arthur Latham, M.A., M.D., &c., &c. Second Edition. Pp. 224. Price 5s. net.
- The Principles and Practice of Asepsis. By Arthur Styles Vallack, M.B. Pp. 95. Price 2s. 6d. net.
- JOHN BALE, SONS AND DANIELSSON, LTD. (London).
The Radical Cure of Corns and Bunions. By E. Harding Freeland, F.R.C.S. Eng. Second Edition. Pp. 34. Price 1s.
- CASELL AND CO., LTD. (London).
The Open-air Treatment of Pulmonary Tuberculosis. By F. W. Burton-Fanning, M.D. Pp. 176. Price 5s.
- CHATTO AND WINDUS (London).
Herbert Fry's Royal Guide to the London Charities. Edited by John Lane. Forty-first Edition, New and revised. Pp. 387. Price 1s. 6d.
- J. AND A. CHURCHILL (London).
St. Thomas's Hospital Reports. New Series. Edited by Dr. H. P. Hawkins and Mr. W. H. Battle. Vol. 32. Pp. 463. Price 8s. 6d. net.
- The Infectivity and Management of Scarlet Fever. By W. T. Gordon Pugh, M.D., B.S. Lond. Pp. 21. Price 1s.
- C. J. CLAY AND SONS (London).
The Harveian Oration delivered before the Royal College of Physicians on June 21st, 1904. By Richard Caton, M.D., F.R.C.P. Illustrated. Pp. 34.
- HENRY J. GLAISHER (London).
The Intestinal Catarrhs. By Edward Blake, M.D. Second Edition. Pp. 356. Price 5s. net.
- A Short Essay on Insanity. By Charles Williams, L.R.C.P., L.R.C.S., &c. Pp. 22. Price 1s. net.
- H. GREVEL AND CO. (London).
Chemistry in Daily Life. Popular Lectures by Dr. Lassar-Cohn. Translated by M. M. Pattison Muir, M.A. Illustrated. Third Edition. Revised and augmented. Pp. 340.
- HENRY KIMPTON (London).
Materia Medica of Vegetable and Animal Origin. With notes on the Properties, Uses and Constituents of Crude Drugs. By John Humphrey. With an Introduction by E. M. Holmes, F.L.S. Pp. 495. Price 5s. net.
- H. K. LEWIS (London).
The New Sydenham Society. Vols. 183 and 184. Tenth, Eleventh, and Twelfth Fasciculi of the Atlas of Clinical Medicine, Surgery, and Pathology.
- J. B. LIPPINCOTT CO. (London).
The Diseases of Society. By G. Frank Lydston, M.D. Illustrated. Pp. 626. Price 15s. net.
- International Clinics. Vol. 4. Fourteenth Series, 1905. Edited by A. O. J. Selby, A.M., M.D. Pp. 314.
- LONGMANS, GREEN AND CO. (London).
Intemperance. By Henry Horace Pereira, Bishop of Croydon. Pp. 173. Price 2s. 6d. net.
- THE MEDICAL PUBLISHING CO., LTD. (London).
Operative Treatment of Chronic Constipation. By W. Arbuthnot Lane, M.S., F.R.C.S. New Edition. Pp. 31. Price 2s. 6d.
- YOUNG J. PENTLAND (Edinburgh).
The Edinburgh Medical Journal. Edited by G. A. Gibson, M.D., F.R.C.P. Edin., and Alexis Thomson, M.D., F.R.C.S. Edin. New Series. Vol. 16. Pp. 560. Price
- THE PRACTITIONER, LTD. (London).
Congenital Dislocation of the Hip. By J. Jackson Clarke, M.B. Lond., F.R.C.S. Second Edition. Pp. 37. Price 1s. 6d. net.

- THE SANITARY PUBLISHING CO., LTD. (London).
Sanitary Law and Practice. By W. Robertson, M.D., Glas., D.P.H., and Charles Porter, M.D., B.Sc. Pp. 756. Price 10s. 6d. net.
The Sewage Problem: a Review of Evidence Collected by the Royal Commission on Sewage Disposal. By Arthur J. Martin. Pp. 363. Price 8s. 6d. net.
Simple Methods of Testing Sewage Effluents for Works Managers, Surveyors, &c. By George Thudichum, F.I.C. Pp. 60. Price 2s. 6d. net.
W. B. SAUNDERS AND CO. (London).
Diseases of the Liver, Gall, Bladder and Bile Ducts. By H. D. Rolleston, M.A., M.D., F.R.C.P. Illustrated. Pp. 794. Price 25s. net.
Atlas and Epitome of General Pathological Histology. By Prof. Dr. H. Durck, of Munich. Edited by Ludwig Hekstoen, M.D. Illustrated. Pp. 371. Price 21s. net.
A Text-Book of Legal Medicine. By Frank Winthrop Draper, A.M., M.D. Illustrated. Pp. 575. Price 18s. net.
A Handbook of Surgery. By Frederic R. Griffith, M.D. Illustrated. Pp. 579. Price 10s. net.
SMITH, ELDER AND CO. (London).
St. Bartholomew's Hospital Reports. Edited by A. E. Garrod, M.D., and W. McAdam Eccles, M.S., F.R.C.S. Vol. xl., 1904. Pp. 207. Price 6s.
JOHN WRIGHT AND CO. (Bristol).
Lectures on Diseases of the Stomach and Intestines for Practitioners and Students. By Boardman Reed, M.D., Illustrated. Pp. 1021. Price 21s. net.
The Naked-Eye Anatomy of the Human Teeth. By Thos. E. Constant. Illustrated. Pp. 194. Price 7s. 6d. net.

Medical News.

The Training of Nurses.

LADY HELEN MUNRO FERGUSON presided on the 22nd ult. at a meeting, convened by the Matrons' Council of Great Britain and Ireland and the Society for the State Registration of Trained Nurses, to "enter the strongest possible protest against the licence of the Board of Trade being granted to a society which seeks to obtain absolute authority over trained nurses." The chairman said that no voluntary association could ever accomplish for the nursing profession what could be done by State registration. At present there was no recognised standard of education for a nurse and no means of control of trained nurses. The registration of nurses by Act of Parliament was the only way by which a general standard of education could be obtained. The following resolution was carried unanimously:—"That this meeting of hospital matrons and trained nurses emphatically protests against the attempt now being made by seven gentlemen in the City of London to obtain the licence of the Board of Trade to incorporate a society which seeks for authority to organise the professional education of trained nurses, to exercise disciplinary powers, and to control their work. This meeting is strongly of opinion that no such powers can be usefully or successfully exercised except by a body composed of professional persons upon which trained nurses have direct and sufficient representation." Another resolution, carried unanimously, ran:—"That this meeting earnestly supports the Bill for the registration of trained nurses, introduced into the House of Commons by Mr. Munro Ferguson, being convinced that the only possible remedy for the present disorganised condition of nursing education in this country, and the many evils now existent in the nursing world, would be the institution of a representative nursing council, empowered by Act of Parliament to supervise nursing education and maintain common rules of discipline in the nursing profession."

Education and Training of Nurses.

A LARGELY attended meeting of the Irish Nurses' Association was held on Friday last to protest against the granting by the Board of Trade of articles of association to the proposed Incorporated Society for Promoting the Higher Education and Training of Nurses. The signatures of the applicants to the Board of Trade are those of Lord Rothschild, Lord Revelstoke, Mr. G. A. Hambro, Mr. S. Hope Morley, Mr. C. H. Goschen, Mr. Hugh C. Smith, and Mr. Cosmo O. Bonsor. It was considered that, however, eminent these gentlemen may be as financiers and philanthropists, they can hardly be considered experts on the education and training of nurses, and that the scheme stands self-condemned by its want of medical and nursing repre-

sentation among the signatories, and it is also most undesirable that a fresh scheme should be submitted to a Government Department while the whole nursing question is under Parliamentary consideration. It was resolved that a petition should be sent to the Board of Trade objecting to the incorporation of the proposed Society; that the Registrars of the Royal College of Physicians and Surgeons should be asked to bring the matter under the consideration of the Fellows with a view to lodging objections; that a letter should be sent to each of the seven signatories informing them of the nurses' view of the question; and that full information be furnished to the Irish members of Parliament. We are informed that the Royal College of Physicians will consider this important matter at their monthly meeting on Friday next.

Royal College of Surgeons in Ireland.

THE annual Charter Dinner of this college was held on Saturday last, and was a most successful function, although the unavoidable absence of the Lord Lieutenant caused some disappointment. Before dinner, the Provost of Trinity College was admitted to the Honorary Fellowship of the College by the President, Dr. Arthur Chance. The President in the course of a short speech referred to the Provost as the head of a great college, a position which he had attained by his varied learning. It was because he was the first member of their profession to hold the office of Provost that the college had asked him to share with them the honour he possessed and so fully deserved. The addition of his name to the roll of Fellows would go far to add to the reputation, the dignity and the honour of the college. The Provost responded after dinner to the toast of "Our New Honorary Fellow." Other toasts followed, and amongst the speakers were Sir Antony MacDonnell, Under-Secretary of State for Ireland.

The "Sanitas" Company.

THE annual general meeting (27th in number) of the "Sanitas" Company, Limited (disinfectant manufacturers) was held on the 22nd ult., under the presidency of the Chairman, Mr. C. T. Kingzett, F.I.C., F.C.S., who congratulated the shareholders upon the continued prosperity of the business and their prospects for the future. Although the past year had not been by any means a favourable one to their class of business, it had, nevertheless, continued to expand, and their sales were greater than in any previous year. Their manufactures included practically all kinds of disinfectants and many sanitary appliances, and "Sanitas Fluid" still easily held first place as a non-poisonous and effective disinfectant for household and sick room purposes. A final dividend of 4½ per cent., and a bonus of ½ per cent., was subsequently declared, making, with the interim dividend already paid, the usual total distribution of 7½ per cent. for the year.

Irish Medical Schools and Graduates' Association.

THE annual general meeting will be held at the Hotel Cecil, Strand, on Saturday, March 18th, at 6.30 p.m. The festival dinner will be held on the same evening, when the Association will dine at the Grand Hall of the Hotel Cecil, at 7.30 p.m., the President, Sir William Whitla, in the chair. The guests of the Association on this occasion will be Mr. Thomas Lough, M.P., and probably Signor Marconi. Application for tickets (7s. 6d. each exclusive of wine), accompanied by remittance, together with the names of guests, should be forwarded as early as possible to E. Canny Ryall, Hon. Sec., 30, Harley Street, London.

The Pharmacy Bill.

A COPY of Mr. Lough's Bill to provide for the further regulation of the sale of poisons and the compounding of medical prescriptions, and to amend the Pharmacy Acts of 1852 and 1868, has been issued. The objects of the Bill are to provide that each shop for the sale of poisons shall be under the *bona fide* personal conduct and supervision of a duly qualified person, and, among other things, that the compounding of prescriptions shall be in the hands only of persons duly qualified to sell "poisons."

Notices to Correspondents, Short Letters, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in re-forwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

ORIGINAL ARTICLES or **LETTERS** intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

VIATOR.—The sale of proprietary nostrums last year reached over £2,000,000. The total revenue amounted to more than £283,000.

GYNÆCOLOGIST.—Cases of galactorrhoea in virgins are extremely rare, but in 1903 Prof. Gauthier of Paris reported such a case in a spinster of 25, who suffered twelve months from it.

DR. W. H.—In selling a practice it is not obligatory to hand over the case books, but the purchaser is entitled to a full list of patients.

R.A.M.C.—One of the handiest volumes is *The Health of Armies in the Field*, by Surgeon-Major Caldwell. It ought to give all you want. The publishers are Billiers, Tindall & Cox.

LIBRARIAN (Hastings).—A surgeon in the British Service, Winterbottom, first called attention to the negro lethargy he had noticed among the natives along the littoral of Benin in 1836.

ANNALS OF NOMENCLATURE.—"Phthisiophobia" is the name given by New Yorkers to those opposing the landing of tuberculous aliens but an enterprising American chemist advertised "Hypophosphitopathy" as his new "cure for consumption."

J. G. HODGSON.—In the hope of escaping a penalty, hypnotism is often given by a prisoner as a scientific excuse and explanation for wrong-doing, but a criminal act implies a criminal intent. Unfortunately, the press in its love of sensationalism is only too willing to lend countenance to these hypnotic theories.

R. T. (York).—There is no lack of good general practitioners in Durban and Johannesburg, but if you would go "up country" a little the chances are fair. The leading medical men generally manage a trip to London every three years in order to keep in touch with medical matters.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, MARCH 1st.

OBSTETRICAL SOCIETY OF LONDON (20 Hanover Square, W.).—8 p.m. Specimens will be shown by Dr. Giles and Dr. H. Williamson. Short Communications: Surgeon-Captain J. C. H. Leicester: A Case of Chyluria with Pregnancy.—Dr. A. H. N. Lewers: A Case of Pregnancy in a Rudimentary Uterine Cornu. The President (Dr. W. B. Dakin): The Present Teaching of Practical Midwifery in England (Inaugural Address).

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chancery Street, W.C.).—4 p.m. Mr. C. E. Ryall: Clinique. (Surgical.) 5.15 p.m. Dr. L. Williams: Dyspepsia and its Treatment.

CENTRAL LONDON THROAT AND EAR HOSPITAL (Gray's Inn Road, W.C.).—5 p.m. Demonstration:—Dr. Abercrombie: Nose.

THURSDAY, MARCH 2nd.

CHILDHOOD SOCIETY AND THE BRITISH CHILD-STUDY ASSOCIATION (Parker Museum, Margaret Street, W.).—8 p.m. Lecture:—Dr. F. Warner: Mental Faculty of the Child, its Growth and Culture. (Arranged by the Childhood Society.)

NORTH-EAST LONDON CLINICAL SOCIETY (Tottenham Hospital, N.).—4 p.m. Paper: Mr. A. de Frenerville: Anæsthetic Difficulties and how to Combat Them.

BOSTON SOCIETY (20 Hanover Square, W.).—8.15 p.m. Discussion on the Necessity of Accurate Measurement in X-ray and High Frequency Work (opened by Dr. W. D. Butcher).

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chancery Street, W.C.).—4 p.m. Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m. Mr. E. Clarke: Ocular Headache: Its Causes, Diagnosis, and Treatment.

MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (7 Fitzroy Square, W.).—5 p.m. Lecture: Dr. T. D. Lister: Bronchial Affections of Children. I. Primary. (Post-Graduate Course.)

FRIDAY, MARCH 3rd.

SOCIETY OF ANÆSTHETISTS (20 Hanover Square, W.).—8.30 p.m. Paper:—Dr. Flux: A Fatality associated with Ethyl Chloride (opened by Dr. McCardie).

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chancery Street, W.C.).—4 p.m. Mr. E. Clarke: Clinique. (Eye.)

TUESDAY, MARCH 7th.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—4.30 p.m. Dr. H. Corner: Mental Affections of Childhood and Adolescence.

Vacancies.

- City of London Hospital for Diseases of the Chest, Victoria Park, E.—Resident Medical Officer. Salary £100 per annum, with board &c. Applications to the Secretary.
- City of London Hospital for Diseases of the Chest, Victoria Park, E.—Pathologist. Salary £105 per annum. Applications to the Secretary.
- Hampstead General Hospital.—Resident Medical Officer. Salary £120 per annum, with allowance for rooms. Applications to George Watts, Secretary, Parliament Hill.
- Paddington Green Children's Hospital, London, W.—Matron. Salary £100 per annum, including washing allowance. Applications to the Secretary, Paddington Green Children's Hospital, London, W.
- Birkenhead Union.—Resident Assistant Medical Officer. Salary £120 per annum, with board, washing, and apartments. Applications to John Carter, Clerk to the Guardians, Poor-law Offices, Birkenhead.
- Navy Medical Department.—Three Dental Surgeons for Portsmouth Plymouth and Chatham. Salary £1 per diem and travelling expenses when necessary. Applications to the Director General, Medical Department of the Navy, 18 Victoria Street, S.W. (See Advt.)
- East London Hospital for Children and Dispensary for Women, Shadwell, E.—Medical Officer for the Casualty Department. Salary £100 per annum. Luncheon is provided at the Hospital. Applications to Thomas Hayes, Secretary.
- Lincoln County Hospital.—Senior Male House Surgeon. Salary £100 per annum, with board, lodging, and washing. Applications to the Secretary, 2 Bank Street, Lincoln.
- Licensed Victuallers' Asylum, Asylum Road, Old Kent Road, London, S.E.—Medical Officer. Salary £200 per annum. Applications to the Board of Management under cover to Alfred L. Annett, Secretary, 28 New Bridge, Street, London, E.C.
- County Borough Asylum, near Middlesbrough, Yorkshire.—Medical Superintendent. Salary £450 per annum, with unfurnished house, rates, taxes, fire, light, washing, and garden produce. Applications to Alfred Sockett, Clerk to the Visitors, Municipal Buildings, Middlesbrough.

Appointments.

- CHAPMAN, WALTER, M.B., B.Ch. Birm., L.R.C.P. Lond., M.R.C.S.**, Public Vaccinator for the Fourth District of the Totnes, (Devon) Union.
- COOK, HERBERT, G. G., M.D. Lond., F.R.C.S. Eng., D.P.H. Camb.**, Medical Officer to H.M. Prison at Cardiff.
- DOUGLAS-CRAWFORD, DOUGLAS, M.B. Edin., F.R.C.S. Eng.**, Honorary Consulting Surgeon to the Liverpool Dental Hospital.
- EVANS, H. W., M.R.C.S. Eng., L.R.C.P. Edin.**, Certifying Surgeon under the Factory and Workshop Act for the Littleport District of the county of Cambridge.
- HAWES, G. C. B., M.B.C.S., L.R.C.P. Lond.**, Certifying Surgeon under the Factory and Workshop Act for the Pangbourne and Whitechurch District of the counties of Berks and Oxford.
- KENT, PRECY WHEELER, M.B.C.S., L.R.O.P., D.P.H. Camb.**, Surgeon to the Glamorgan County Police at Barry.

Births.

- HENRY.**—On Feb. 27th, at Wincott House, 175 Kennington Road, S.E., the wife of George Nicol Henry, M.B. C.M., of a son.
- JELLETT.**—On Feb. 27th, at 61 Lower Mount Street, Dublin, the wife of Henry Jellett, M.D., of a son.

Marriages.

- BOWLE-CUFFE-ADAMS.**—On Feb. 24th, at St. Mary's Church, Isleworth, Clement Bowle, R.A.M.C., second son of Edward Bowle, Esq., of Salisbury, to Marjorie, daughter of Mrs. Charles Cuffe-Adams, and the late Charles Cuffe Adams, Esq., of Ealing.
- HENMANS-TINLEY.**—On Feb. 15th, at All Saints' Church, Holbeach, Lawrence Fielder Henmans, M.B., of 9 Lewisham Park, S.E., to Harriet Annie, elder daughter of the late Joseph Tinley, of Holbeach.
- SHELDON-CAITHNESS.**—On Feb. 25th, at St. Peter's, Ealing, Walter Sirt, M.B.C.S., L.R.C.P., eldest son of Thomas Sheldon, M.D., J.P., of Powis Square, W., to Ethel, second daughter of the late James Ernest Caithness and Mrs. Y. E. Caithness, of Berrisdale, Ealing.

Deaths.

- ALLEN.**—On Feb. 26th, at 3 Carlisle Parade, Hastings, Ella Louise Katherine, wife of Bryan H. Allen, M.D., and daughter of the Rev. R. H. Dover, late Vicar of Wisden, Yorkshire, aged 56 years.
- BROWNE.**—On Feb. 21st, Charles Browne, F.R.O.P. Edin., &c., youngest son of the late Tobias Browne, of Camberwell, aged 72.

Original Communications.

A TYPHUS FEVER OUTBREAK IN LONDON IN 1899.

By F. J. WALDO, M.A., M.D. Cantab., D.P.H.,
Coroner for the City of London; late Medical Officer of Health
for the Parish of St. George-the-Martyr, Southwark,
London, &c.

THE recent appearance of typhus in the East End of London reminds us that the disease in question is an ever-present danger. Typhus fever is so highly infectious, so deadly, and liable to so many variations in its symptoms that medical men will do well to refresh their minds with a review of its chief characteristics. Some years ago, while acting as Medical Officer of Health for a large and populous parish in South London, it fell to my lot to investigate the history of several cases of typhus fever in my district. The resulting record showing the train of infection and the pitfalls of diagnosis associated with unrecognised typhus, is so striking that I venture to republish my original report presented to the sanitary authority of St. George-the-Martyr, Southwark.

On February 28th, 1899, a case of typhus fever was notified to me as occurring at No. —, Southwark Bridge Road. On inquiry I found that the patient had come from Bermondsey suffering from the malady, and that several of her relatives had been attacked with mysterious illnesses. During 1898 two other cases of typhus fever occurred in this parish. The first of these was in April and was traced to Kensington, but did not spread in St. George's. The second occurred in October, and its origin could not be ascertained. Some of the members of the infected family went to a house in Bermondsey, where the disease subsequently developed. Under these circumstances it occurred to me that there might be a possible connection between the case notified to me last October and the one brought to my notice in February. On inquiry I found such a connection, and was enabled to trace the following interesting and suggestive train of events:—When the first case was notified I closed the house and induced all the inmates to enter the reception house, with the exception of the father, who went away and slept two nights at No. — (a), Minto Street, Bermondsey. This fact I at once communicated to the Medical Officer of Health of Bermondsey. In the house at No. — (a), Minto Street, there were resident four families. On or about December 15th, Mrs. F., a resident at No. — (a), was taken ill, and was admitted to Guy's Hospital on December 18th. She was there treated for supposed enteric fever, and was discharged to a convalescent home on January 22nd. The father's visit to No. — (a) was paid to his son and daughter-in-law, who on December 24th, 1898, removed to No. —, Tabard Street, Newington. On January 13th, 1899, the son was taken ill, and removed in a delirious con-

dition to Newington Workhouse, where he died on January 18th. The wife of the last patient was taken ill about the same date, and died at the aforesaid No. —, Tabard Street, on January 14th. Returning to No. — (a), Minto Street, we find that Mrs. F., who was first attacked there on the night before she went into Guy's, called at No. — (c), Minto Street, and arranged for one of her boys being taken there as a lodger. At the same time she interviewed a woman from No. — (b), who undertook to take charge of a second son. Towards the end of January the son, who had been left at No. — (b), Minto Street, was removed to St. Olave's Union Infirmary, where he still remains at the time of report (March 13th, 1899). Returning to No. — (c), Minto Street, we find it inhabited by the W. family—father, mother, three sons, and two daughters—and the recently admitted son of Mrs. F. Seven of these eight persons were admitted to hospital at various dates up to March 7th, and all these cases have been recognised, either at the time or subsequently, as typhus fever. The son, Richard W., was taken ill on January 14th, and admitted on the 19th to King's College Hospital, where he died on the 30th. The son, Frederick W., was notified as enteric fever on February 11th, admitted to Guy's Hospital, found later to have typhus fever, and sent to the South-Eastern Fever Hospital.

F.'s son was notified enteric fever on February 15th, sent to Guy's Hospital, also found later to be suffering from typhus fever, and dispatched to the South-Eastern Fever Hospital, where he and Frederick W. still remain. Mrs. W. was admitted on February 14th to the Park Hospital, where she is still under treatment. The father was notified as enteric fever on February 18th, and taken to Guy's Hospital, where he died on the 22nd. The daughter, Alice W., entered Guy's Hospital on March 4th, and was sent to the South-Eastern Hospital with typhus fever on March 6th. The son, George W., went into St. Olave's Union Infirmary on February 21st, and was removed with typhus fever on March 7th to the South-Eastern Hospital.

My own patient, Mrs. B., was notified on February 20th, from Guy's Hospital, as having resided at No. —, Southwark Bridge Road, in the parish of St. George-the-Martyr. She had removed to that address two days previously from No. —, Weston Street, Bermondsey. On inquiry, a direct communication with the group of cases at No. — (c), Minto Street, was established by the fact that she sat up one night with her brother, Richard W., while a patient at King's College Hospital, where he died, as already stated, on January 30th. Other cases doubtful in nature and origin are still under investigation.

On the strength of the above facts, I think we may be fairly justified in arriving at the following conclusions:—1. That there has been a direct

chain of communication between the two cases of typhus fever notified in the parish of St. George-the-Martyr on October 19th, 1898, and February 20th, 1899. 2. That the infection was carried out of the parish by the father of the first patient. Had he entered the reception house with the rest of the family in all probability the centre of original infection would have been stamped out.

In conclusion, I have to acknowledge the cordial assistance afforded me in the course of the above investigations by the authorities of the various hospitals, the Medical Officer of Health, and the local medical men concerned.

THE ETIOLOGY OF CARCINOMA: DOES IT PERFORM ANY PHYSIOLOGICAL FUNCTION? (a)

{ By GEO. THOS. BEATSON, C.B., M.D.Ed.,

Lieut.-Col. Royal Army Medical Corps; Surgeon to the
Glasgow Cancer Hospital.

SOME recent utterances, he said, favoured the idea that carcinoma was a microbic disease. To name only the latest researches, neither Doyen's work nor that of Ford Robertson and Wade had yet fulfilled Koch's criteria. If Doyen's serum actually had the specific curative reaction claimed for it then it would prove the correctness of the theory of the microbic origin of the disease. In the published accounts of cases treated by Doyen's method there is conspicuous absence of evidence of changes in the cancer-cells, and stress is chiefly laid on the increased mobility of the tumours. Such an increased mobility was only what was to be expected from the use of a serum, because a great part of the fixity of malignant growths was due to small-celled infiltration. A serum derived from microbic tissue might well influence favourably this small-celled inflammatory deposit, and by loosening and defining the boundaries of a neoplasm be a valuable adjunct to operative procedures, just in the same way as Watson Cheyne advocated the preliminary use of antistreptococcal serum in operations for excision of the tongue in order to diminish sepsis. The speaker was more and more inclined, however, to regard carcinoma as a tissue vice, and to advocate the germinal theory of its origin, a view to which he had been led by the remarkable results of oöphorectomy in mammary cancer. Analysis of the reported cases in which this had been done was favourable to the procedure. Hewlett's recent collection showed that not less than 36 per cent. of the cases had benefited. The result of oöphorectomy was an increase of the stroma of the tumour and a fatty degeneration of the cancer-cells—that is, conversion of the tumour into a fibro-scirrhous carcinoma. If the germinal theory of cancer were true, we ought to find among cancer cells signs of the activities characteristic of reproductive tissue, *i.e.*, extension of polar bodies and reduction of the chromosomes. With the assistance of Dr. Ernest Fortune, a number of specimens had been examined to this end, but they had not found unequivocal evidence of extension of anything like polar bodies, and on account of the great difficulties involved in the task no very prolonged search had been made for signs of reducing division. A series of observations had

been made on the effects of inoculating rabbits with testis and ovary, but without positive result. Confirmation of the germinal theory, however, had been recently afforded by Farmer's researches on mitoses in cancer-cells. It was important to remember that the cell was the essential feature of the carcinoma—not the stroma. The characteristic of the tumour was the fact that it was composed of large polygonal cells irregularly distributed, with no nerves, vessels, or lymphatics, and no tendency to organise like ordinary granulation tissue. The stroma consisted of the pre-existent elements, among which the cells were forced; such cells, of course, were prone to degenerate easily; they proliferated only to perish, and had no constructive power. Another evidence that cancer-cells were part of the tissues of the body and not microbic in origin was the fact that they were non-irritating, as was shown by the fact that local secondary growths did not reveal themselves by any signs until they had attained a considerable size. Hence in many cases delay in seeking medical advice was inevitable on account of the latency of the symptoms. Dr. Beatson, however, protested emphatically against the advice that in order that cancer might be recognised in its early stages information as to the symptoms of the disease in its incipient period should be disseminated broadcast. People should be taught to consult their medical advisers when definite symptoms arose, irrespective of what they were due to; but to raise the spectre of cancer in the minds of the laity by inculcating the doctrine that the most trivial signs might be due to malignant disease would be to superinduce a frame of mind in which anxiety and fear would actually go far towards producing what they wished to prevent. Some peculiar appearances noticed in the fat of cancerous patients were then mentioned. The bodies of cancer patients were sometimes strikingly well nourished, and the fat was highly pigmented and of the reddish-yellow colour of yolk of egg. This was possibly associated in some way with the lemon-yellow tinge of the cancerous cachexia. Again, he had often observed an oily fluid state of the fat at operations, and in these cases there was a greater tendency to dissemination of the growth than persons of spare habit. He had endeavoured, though without success, to elucidate the nature of this abnormal pigmentation; the chemistry of the pigments of human fat was a matter about which very little was known. In both the ovaries and testes the reduction of the chromosomes and extrusion of polar bodies preceded maturation of the germ cell, and maturation was accompanied by a rapid growth of cells. He took it that there must be in the body some stimulus to this reducing division and extrusion of polar bodies, and this stimulus he believed to be a fluid in the tissue juices; it might either be a secretion of some particular organ or of all the tissues. In castrated persons there was a tendency to the deposit of fat in the body; this he regarded as due to a storing up or diversion of this fluid from its proper end, namely, the stimulating of reproductive cells. The current view of cancer, that it occurred irrespective of the requirements of the body, was possibly not correct. It was a mere assumption that the proliferation of cancer-cells was autonomous; possibly cancer-cells functioned in place of others which had passed into a state of inactivity. Recent investigations on the rounded

(a) Abstract of Paper, specially reported for this Journal, at a meeting of the Edinburgh Médico-Chirurgical Society, March 1st, 1905.

bulbs or nodules on the roots of healthy bean and clover plants were specially interesting. These tumours or nodules varied from the size of a bean to that of a potato, and were found to be packed with bacteria, which were constantly absorbing nitrogen from the air and feeding the plant. This fact had been made use of in scientific agriculture by inoculating soils with these bacteria to increase their crop-bearing power. Here, then, was a tumour which played a beneficial part in the life of its host. Now, Farmer and his colleague had shown that cancer-cells revealed a reducing division, therefore they might assist, or even replace, the reproductive cells. Carcinoma had an action not unlike that of the testes and ovary; it was constantly throwing off cells, some of which proliferated, and others degenerated. Operation on cancer had some bearing on the view that the tumour was a secreting organ. If they were successful, the patient rapidly put on fat; this he supposed to be due to a cessation of the drain from the tissue of the procreative fluid used up by the tumour. The procreative fluid in the tissues which was not dealt with by the testes or ovaries, on account of their function having fallen into abeyance, or for other reasons, was stored up by the fat, but the fat could not go on storing it up indefinitely, and so at last it stimulated some of the body cells to take an activity analogous to that of the reproductive cells—that is, to become carcinomatous.

THE APPLICATION OF PLASTER OF PARIS FACILITATED BY ANEW APPARATUS. (a)

By W. I. WHEELER, M.D.,

Surgeon to Mercer's Hospital, Dublin.

THE application of plaster of Paris to recent fractures has gained favour, not only on the Continent, but also in London, and to a lesser extent in Dublin within recent years; however, whether plaster be applied immediately, or at any time subsequent to the injury before union has taken place, many difficulties arise in its application which are especially noticeable when it is intended to secure the entire limb and pelvis in a plaster casing when the femur is broken. For instance, it is impossible by the existing methods to fix the leg and pelvis in plaster of Paris with any certainty that the deformity has been accurately corrected, or that sufficient extension has been maintained to reduce permanent shortening to a minimum. During the operation two or three assistants were always essential, and when the pelvis was reached, the greatest awkwardness accompanied the hoisting of the patient off the bed or table at every roll of the bandage. With these manipulations it was unlikely by the time the plaster was completely on that the fragments had remained in proper apposition.

Various appliances have been thought of to overcome the difficulties enumerated above. The principles of the machine about to be described were suggested to my mind by a device described by Agnew twenty years ago, and also by the knowledge that various surgeons, notably Kocher, of Berne, and Doyen, of Paris, have appliances to aid them in the accurate setting of fractured femurs, and their results show many cases where no permanent shortening has existed. Even

(a) Read before the Surgical Section of the Royal Academy of Medicine in Ireland.

Agnew, by the device just alluded to, treated fractured femur by the primary plaster method, with results very rarely surpassed at the present day. His apparatus consisted simply in an upright bar well padded and fastened to the end of a table to receive the perineum. A horizontal bar attached to the upper end of this, extended backwards parallel to the patient; the latter was slung by a towel to this, so as to raise him slightly from the table, and thus to give easy access to the pelvis, which was encased in plaster of Paris, together with the entire limb on the fractured side. This machine, simple and easily extemporised, did not overcome the disadvantages of having to rely on an assistant to keep up extension during the application and subsequent drying of the plaster. Such extension is likely to be very inaccurate, and there is no guarantee that it is not relaxed at intervals, or that the two legs are ever exactly the same length. An error in this respect is rendered all the more likely by the fact that relative abduction and adduction of the two legs can usually only be roughly estimated. Indeed, obliquity of the pelvis is a factor likely in these cases to cause considerable error in estimating length.

A modification of Doyen's apparatus I have seen used allows free access to the limbs, but not to the pelvis. It registers abduction but does not provide for extension, and therefore fails to supply two of the most necessary requirements for the treatment of these injuries. Kocher's apparatus I have not had an opportunity of seeing in use. It is very perfect, but an expensive and somewhat complicated machine, fitted with a system of dynamometers, which ensure the greatest accuracy. It is necessary before describing the application of the plaster to call special attention to an elementary point, but one often disregarded, *i.e.*, that it is well worth while to make sure that the plaster itself is thoroughly reliable in all respects, because after an extensive application, and where much trouble has been taken to accurately reduce the fractured limb, it is most disappointing if the dressing is found defective, either failing to set or else cracking in the places where strength is most required. As an example of the latter, the groin may be mentioned, and it is wise to apply strips of aluminium or lead, or bits of sticks through the plaster in this region, to give it strength.

The apparatus (Figs. 1, 2, 3) is very simple and inexpensive. It consists essentially of two iron gates (E) about four and a half feet long, swung on an upright (B), which latter is surmounted by a padded crutch (A), so shaped that a small portion of the padded surface is horizontal (X), and will afterwards be seen to support the coccyx and lower part of the sacrum when plaster is being applied to the pelvis (Fig. 3). The crutch and upright on which it sits are supported by a heavy stand (C) with two diverging legs on each side drilled with holes, so that if required it can be screwed permanently to the ground; this, however, is not necessary. At the distal end of the gates can be seen a roller (D) over which the bandage is placed while extension is being applied. The roller is square on section in order to obtain a firm hold on the bandage, and also because, when sufficient extension is obtained, by gently pushing the handle inwards the square bar fits into a hole of the same shape and diameter, and so locks. By this means,

FIG 1

FIG 2

FIG 3

every quarter-turn the handle can be fixed, a simple substitute for a ratchet.

Now comes an important part of the machine, a bar (F) fixed to the stand and running at right angles to it between the two gates. To the end of this bar a graduated curved iron is attached (G), so that the gates can be diverged from the middle line each to a measured amount, and so the limbs abducted to the same extent. By this method there can be no obliquity of the pelvis.

To make the apparatus complete two Salter's sportsmen's balances are necessary, registering at least fifty pounds, so that by attaching these to the rollers the extension can be accurately measured, and the same amount applied on both sides if required (H).

I will now briefly describe the setting of a fractured femur on the new apparatus either immediately after the injury or at any time subsequently before union has taken place, according to the indications present. The patient being anaesthetised, the apparatus is brought to the end of the table, which is raised or lowered until the horizontal part of the crutch is level with the surface of the table (Fig. 1). If the table cannot be raised or lowered, it would be better to have the crutch fitted like a bicycle saddle in order to be able to make it any required height.

A clove hitch is applied to the ankle, the latter having been first well padded with wool, or, better, a skein of knitting wool is applied to the foot (figure 8 fashion) and fixed by a bandage, as recommended by Watson Cheyne. Either of these will do for extension purposes. A leather anklet with stirrups would serve the same object.

The patient is now brought to the end of the table astride the crutch (Fig. 2), the surgeon taking

charge of the injured limb. The skein of wool, or whatever is used, is attached by a bandage to the iron roller, the graduated balances intervening. Both legs having been thus fastened, the gates are opened to the same measured extent; this will vary in different cases. The limbs can now be accurately measured and extension put on by means of the rollers until both are equal; they are then securely held by the apparatus in this position. The plaster is rapidly rolled on, there being free access to the leg, until the pelvis is reached. The table is now lowered two or three inches, the coccyx and last bit of the sacrum are supported on the crutch, the back becomes arched, and a space remains between the table and the greater bulk of the pelvis, round which the roller bandage can be continued without any assistance, and little disturbance of the patient (Fig. 3). It is recommended not only to encase the injured limb and the pelvis, but also to continue the plaster down the sound limb as far as the knee, and thus secure the immobility of the pelvis, and provide counter extension at the perineum.

It is wonderful to see how well patients can walk with crutches, and even sit down after a fashion, with one and a half legs in plaster together with the entire pelvis, and it is safe to allow them to do this in many cases four or five days after the accident, provided the plaster be firm, and all the weight is kept on the sound leg; a bandage round the neck supporting the injured limb.

It must not be thought that this device is only of use to those who apply plaster as a primary treatment; it is hoped that it may also be of service to everyone who uses plaster of Paris at any period during the treatment of fractured thigh bones, and also during certain operations on the bones where extension is required and a plaster dressing used.

I have treated five or six cases in this manner with success in every instance; the plaster was rapidly applied, scarcely any assistance was necessary, and the patients expressed themselves free from pain and more comfortable than when a McEntire's splint or weight and pulley was used. An oblique fracture in an adult near the middle of the shaft is the most suitable case. In a great number there should be no permanent shortening in fractured femur, and there have been many such results in this country and abroad.

I am indebted to Dr. Haughton's paper read before the Academy two years ago for much information on this subject; and to Dr. Harnett, one of the house surgeons at St. Thomas's Hospital, London, for showing me many cases of fractured femur treated there by the primary plaster method.

One of the residents in Mercer's Hospital (Mr. Smith) was kind enough to act as model while photographs were being taken from which the accompanying illustrations have been made. Finally, it is quite obvious that some cases of fractured femur could not be treated by the method described, with the apparatus in its present form, but a few alterations which have been presented to me would make it, I think, suitable for almost every case.

Vaccination Grant.

MR. PHILIP E. HILL has been awarded for the fourteenth time in succession the Government grant for efficient vaccination in the Crickhowell district of the Crickhowell union.

ORGANISED AND SYSTEMATIC RESEARCH IN OTOLOGY. (a)

THE PRESIDENTIAL ADDRESS,

By THOS. BARR, M.D., F.F.P.S.Glasg.,
Lecturer on Aural Surgery, Glasgow University; Senior
Surgeon to the Glasgow Hospital for Diseases of the Ear.

AFTER thanking the members for the honour conferred on him by his election as President of the Society for the second year, he said: My first aspiration is the institution of organised and systematic research in connection with the Otolological Society. I would ask, is there any part of the body which presents problems so eminently demanding research as that with which we have to do? Difficult problems, complicated problems, we are sometimes apt to think insoluble problems. By means of organised and systematic research, we could grapple more closely with these difficulties and hope to solve at least some of them. As one subject well worthy of research I would suggest the further elucidation of the pathological conditions present in ear disease, especially in the dry, non-purulent middle-ear forms, by more thorough clinico-pathological methods, so as to help in differentiating their varieties more accurately; this differentiation being, I think, one of the main conditions of advance in treatment.

I am probably correct in saying that, since the time of Toynbee, the pathological anatomy of the ear has not received adequate attention in this country. There is probably no region of the human body so habitually ignored by the pathologist in the *post-mortem* room, and yet there is probably no part where it is so important in the interests of progress that such an examination should be made, and that thoroughly. The difficulty of the processes involved in both the macroscopic and microscopic examination of the ear and the apparent lack of any practical result commensurate with the trouble have, I fear, deterred many. The British type of mind is essentially a practical one, and is impatient to see definite and immediate fruit resulting from its labour. It may be held that the otologist himself should see to the examination of any specimen coming from his hands, but this is, with the most of us, impracticable, as the thorough examination of the temporal bone and organ of hearing requires more time and technical experience than fully-occupied otologists can usually command, while the operative work which now falls to the otologist renders it, perhaps, undesirable that he should engage in *post-mortem* work.

Might it not, therefore, be possible to make arrangements with gentlemen at important centres, say, young men having in view the practice of otology and duly qualified by pathological training for the work, by which temporal bones, sent by any member of this Society, might be examined anatomically and pathologically and reported upon? Instructions might be issued to members how to prepare such specimens for safe transmission, forms of questions might be furnished to elicit the clinical history of the person from whom the specimen was removed, when that is possible. Our dissections and specimens have hitherto lost much of their value owing to the

(a) Delivered at a meeting of the Otolological Society of the United Kingdom, February 6th, 1905.

frequent absence of such clinical records, and, if such an investigation were to be profitable, this lack must in future be supplied. With the knowledge that specimens would be thoroughly utilised, members would be more on the outlook for suitable prospective cases, perhaps putting themselves in communication with physicians in general hospitals or in parochial or workhouse hospitals. In this way members might become aware of appropriate cases in such institutions—such as patients suffering from fatal diseases, and at the same time the subjects of deafness or ear trouble. Those, when known, might be carefully examined clinically, so far as the ear and hearing are concerned, with the expectation that, if brought to the *post-mortem* room, the temporal bone or other implicated parts might be removed and subjected to careful examination under the light of the clinical records.

No doubt it might be difficult to find young pathologists fitted for this work. Such a pathologist must be specially interested in otology, and all the better if engaged in clinical work with the intention of following up the specialty. What a splendid foundation would a year or two of this work form for the life work of the future practical otologist.

I am afraid, however, that such a scheme, to be successful, would involve the expenditure of money. We have, unfortunately, no research fund, such as is possessed by the Odontological Society, but I believe there are sources from which funds could be obtained to aid in such research, if any of our members, or even suitable gentlemen outside the Society, were willing to undertake the work under the supervision and co-operation of this Society.

My second aspiration is the formation of a permanent museum of anatomical and pathological specimens, including also instruments, models and appliances for the teaching of otology, a place to which members might resort for leisurely inspection and study. Speaking as a member hailing from the distant provinces, such a museum would prove specially attractive. Those of us who live at a distance from London have sometimes a few hours to spare on the day of the meeting, as I had lately, when, having no museum to inspect, I placed myself under the courteous guidance of Mr. Bethell and surveyed the premises of the Medical Society. I was conducted for the first time to our library, which I am bound to say presented a very modest appearance, "cabined, cribbed, confined" within the limits of a few feet of shelving. In looking, however, at its very limited proportions, I reflected that many great things spring from small beginnings, and that these meagre shelves might present the "promise and potency" of a future great library. I confess, however, that I did not keenly feel the lack of a great library, because, after all, most of us have very little difficulty in procuring, wherever we are, any book we may desire. I felt that the contents of a museum were the books I should have liked to peruse during my hours of waiting. There is no doubt that our department lends itself to the production of anatomical and pathological specimens, both microscopic and macroscopic. The temporal bone itself is a perfect mine of possible specimens, without taking into account the neighbouring cranial, nasal and pharyngeal cavities. We saw what could be done in the splendid collection of the

memorable museum of 1899, a valuable and permanent souvenir of which is to be seen in the volume prepared by Mr. Arthur Cheatle and Dr. Jobson Horne. The only pity was that such a unique collection, gathered together with so much labour, was open to inspection for only one short week.

I am confident that, if we had a place for their reception, we would soon have a collection forming a great attraction to our members. There are many sources from which we might draw. For example, if research work were set agoing the museum would naturally become the home of the specimens resulting from research. Each of us, I am sure, would contribute something from time to time. Donations from outside workers would, no doubt, be forthcoming, when it became known that this is a feature of the Society. Legacies from private museums might also be looked for in time. It is even conceivable that the Royal College of Surgeons might hand over Toynbee's historical specimens, which would form a grand nucleus, as well as a stimulus to future workers. In such a museum I would look forward to a department for instruments, into which every member of the Society, who might devise something new, would be expected to place a duplicate. Other otologists, not members of this Society, might be disposed to do the same. Instrument makers, both at home and abroad, would, I believe, contribute to such a collection, and would, no doubt, if invited, be willing to show from time to time, perhaps on the days of our meetings, new instruments or appliances bearing upon our department. This would especially prove a boon to country members, who would thus be saved the trouble of visiting instrument makers' establishments in search of new and improved instruments. Even models, diagrams, casts, &c., might appropriately find their places in such a collection and be helpful, especially to those of us who are engaged in teaching. The possibilities of usefulness connected with such a scheme are almost limitless. If the gentlemen who did so much to make the London Museum of 1899 so striking a success would take this matter in hand, our museum would soon become an accomplished fact, and from a small beginning it would, ere long, expand, and I would not be surprised were it ultimately to reach the dimensions of that of 1899—a permanent source of interest and education to all otologists.

Clinical Records.

ROYAL FREE HOSPITAL.

Case of Prostatectomy and Lithotomy.

Under the care of Mr. JAMES BERRY.

[Reported by Mr. A. W. HOGG, House Surgeon.]

THE following is a short summary of the notes of a case of enlarged prostate in a man, æt. 67, who was sent up to the Royal Free Hospital on October 6th, 1904, by Dr. Franklin Eminson, of Scotter, complaining of painful and frequent micturition and frequent attacks of retention.

History.—About ten years ago patient began to have slightly increased frequency of micturition, especially at night. Two years later, after exposure to cold and damp, he suffered from retention, and for six months afterwards his urine had to be drawn off with a catheter. Since then there has been more or less urinary trouble, although now and again there have been intervals, sometimes as long as three months, of comfort. Pain has been present at times. Dribbling

of urine has been a marked feature of the case during the greater part of patient's trouble. Blood has been occasionally present, but this was attributed to catheterisation. The urine was noticed frequently to be thick and muddy-looking, and it was observed that at such times the pain was more severe. There is no history of stone or gravel. Family history good. Previous health good.

Urinary System.—The following are a few points concerning the urine: October 6th (day of admission), quantity, 16 ozs.; sp. gr., 1020; reaction, acid; pus present. 7th, quantity, 24 ozs.; sp. gr., 1020; reaction, acid; pus and stellar phosphates. 8th, quantity, 39 ozs.; sp. gr., 1015; reaction, acid; pus and stellar phosphates. 9th, quantity, 49 ozs.; sp. gr., 1013; reaction, neutral; pus and stellar phosphates; urea, 1.3 per cent. 10th, catheter specimen faintly acid; albumin, blood, and pus; urea, 1.45 per cent. Other systems quite normal. Temperature on admission, 97° F.; pulse, 64.

Local Condition.—On examination *per rectum* a round, smooth swelling, firm in consistence and without pain on pressure, was felt in the region of the prostate.

Diagnosis.—Simple enlargement of prostate and cystitis. The patient was at once put on acid sodium phosphate and urotropin.

Operation.—On October 15th, Mr. Berry did a suprapubic cystotomy. After washing out the bladder with warm boracic lotion, a few ounces of which were left in, likewise a silver catheter in urethra, an incision 3 ins. long was made in middle line of abdomen beginning just above the symphysis pubis. The peritoneum being pushed up, the bladder was exposed and opened by a vertical incision downwards. The catheter was at this stage withdrawn, and the operator's left middle and forefingers having been introduced into rectum, the prostate was pushed forwards. Mr. Berry then divided the mucous membrane over the prostatic growth and enucleated two adenomata—one a roughly globular mass, 2½ ins. by 2½ ins., the other somewhat larger and more irregular, with a diameter of 3 ins. Both tumours were encapsuled and weighed together 3 ozs. The bladder was next washed out and two large drainage-tubes, and also a gauze drain were inserted, reaching to the bottom of the bladder. Finally, a dressing of 1-2,000 bichloride of mercury was applied. The whole operation took eleven minutes.

Progress.—The patient had a rigor lasting ten minutes on recovering from anæsthetic, his temperature rising to 102°, pulse to 104. These, however, soon returned to normal. The gauze drain was withdrawn the same evening, and the bladder washed out with boric solution *per urethram*. The irrigation was repeated five times during the night.

On October 11th the bladder was irrigated five times. 12th and 13th.—Four irrigations in the twenty-four hours.

14th.—Three irrigations in the twenty-four hours.

15th.—Three irrigations in the twenty-four hours. Patient passed a small quantity of urine naturally.

17th.—Patient up for a few hours.

19th.—Irrigations twice in the day.

24th.—A little urine passed naturally—alkaline in reaction and containing some blood and mucus.

November 2nd.—Bladder irrigated once a day, but suprapubic wound dressed every eight hours as dressings got soaked with urine. One to four ounces passed naturally.

5th.—Catheter tied in, but could not be retained owing to difficulty in keeping it in place.

8th.—Drainage not being satisfactory it was decided to do a mid-perineal cystotomy.

11th.—**Operation:** The bladder having been first washed out, both suprapublically and *per urethram*, the wound in the prostate was scraped out and found to contain much granulation tissue, covered with much phosphatic deposit. From the bladder a piece of membranous-looking structure covered with phosphates was washed out. This was thought to be the sloughing remains of part of the prostatic capsule. A calculus about the size of a damson stone was also found and removed. The bladder was again irrigated thoroughly, and the

patient then put into the lithotomy position, and a mid-perineal section performed. A drainage-tube about 4 ins. or 5 ins. long and about ½ in. in diameter was introduced through this opening into bladder, which was again irrigated to see if drainage were quite free. The wounds, suprapubic and perineal, were dressed with gauze wrung out in 1-2,000 hg. Cl.

Progress after this operation was as follows:—

November 12th.—Bladder is being well drained through tube in perineal wound.

13th.—Perineal tube removed, but as drainage not quite satisfactory it was reintroduced and left in until November 23rd. The bladder during these ten or eleven days was irrigated *per urethram* every second day. The amount of urine passed every night about this time was about 16 ozs. to 22 ozs.; alkaline in reaction, and contained albumin.

November 28th and 29th.—As little or no urine had been passed naturally, Mr. Berry passed Lister's bougies 11-14 and 12-15 through urethra into bladder.

30th.—A catheter, No. 11, was tied into urethra and 32 ozs. of urine passed. The suprapubic wound was quite closed, and perineal was gradually becoming smaller.

December 9th.—Patient passed 2 ozs. to 3 ozs. naturally.

14th.—Patient passing nearly all his urine naturally; perineal wound nearly closed.

21st.—Patient went home quite well and with both wounds healed.

Except for some slight attacks of bronchitis the patient's general condition during his stay in hospital was extremely good.

On account of the alkaline reaction of the urine, patient had always beside him the following medicine:

Sodii acid. phos., 1 drm.;

Urotropin, 5 grs.;

Syrup limonis, 1 drm.;

Aq. ad 1 pint; t.d.s.

REMARKS BY MR. BERRY.

The chief interest of this case lies in the fact that besides the enlargement of the prostate there was a small calculus in the bladder which was not suspected or discovered at the time of the first operation. The value of urotropin and acid phosphate of soda in correcting alkalinity of the urine is well known. The patient was put on the above-mentioned mixture of these drugs several days before this operation and continued to take between two and three pints of it daily throughout his stay in the hospital. Nevertheless, his urine until after the second operation was never quite clear, and to this must be attributed the failure of the suprapubic wound to unite and the deposition of phosphates upon the prostatic wound. After removal of the calculus and the clearing away of the phosphatic deposits, the urine soon became clear, and the wounds healed up. It is well to note that acid phosphate of soda should be given in large quantities of water. Made up in the manner above mentioned, it forms a palatable drink like lemonade, and the patient should be encouraged to drink as much of it as he can, generally three or four pints per diem. In ordinary cases of simple prostatectomy, the urine can by this means be kept quite sweet and the wound in the bladder, if kept aseptic, heals readily. Another important point in the treatment of a patient after prostatectomy is to drain the bladder thoroughly for a few days by means of two large tubes in the suprapubic wound and to get the patient up early, if possible within three or four days of the operation.

Transactions of Societies.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD FRIDAY, FEBRUARY 3RD, 1905.

C. M. TUKE, Esq., President, in the Chair.

MR. J. D. MALCOLM read a paper on "Extra-Uterine Fœtation," and divided his observations on the subject

into *first*, a short description of the natural history of the condition; *secondly*, the points on which a diagnosis may be founded; and *thirdly*, the indications for treatment. Mr. Malcolm said that in a large number of cases of extra-uterine foetation a fairly certain diagnosis was possible from the history of the case alone. As a rule, menstruation is delayed for a week or two, or even a month or two, and then comes on irregularly, but cases are recorded where there has been amenorrhœa during the whole period of extra-uterine foetation. If, in addition to the irregularity just mentioned, a woman is seized by a sudden pain in the pelvis with symptoms of collapse, suspicion of extra-uterine foetation becomes almost a certainty. Severe hæmorrhage may occur before the patient has missed a period, in which case examination yields but little information, as the foetal sac is small, and the escape of blood makes the parts so soft that they can hardly be felt. If the blood escapes into the broad ligament, the uterus would be dragged and pushed upwards to the healthy side, but if the blood escapes into the peritoneal sac, it is very difficult and sometimes impossible to detect it. There may, therefore, be only the symptoms to indicate the condition. These are severe pain, vomiting, hæmorrhage and collapse. Under these conditions a definite diagnosis between a ruptured Fallopian tube and a strangulation or ruptured viscus is impossible, except by opening the abdomen. Later on, when a gestation sac can be felt, or when a clot forms, physical examination is important. When progress has advanced so far that the foetal parts may be defined, there should be no difficulty in diagnosis. With reference to treatment, Mr. Malcolm said that when profuse hæmorrhage is diagnosed there should be no delay in operating. The more serious the condition of the patient, the more urgent is the necessity for operative interference. The bleeding vessels are generally and most quickly secured by removing the ovary and tube. If symptoms are not urgent, the patient should be kept absolutely quiet in bed, and arrangements for an immediate operation made should hæmorrhage recur. If there is no further hæmorrhage, but a growing mass be found in the pelvis, operative treatment should be resorted to, but if a mass remains without any change of size, a further period of rest should be insisted upon. A considerable proportion of such cases will get well without surgical interference. When pregnancy is more advanced, and it is diagnosed that there is a living foetus developing outside the uterus, an operation should be undertaken without delay. If the foetus dies when pregnancy is fairly advanced, and there are no urgent symptoms, the question of operating may be open to discussion.

Mr. J. A. MANSELL MOULLIN could not accept Mr. Malcolm's views as to treatment of cases where a hæmatocele had formed, and considered that in all cases of pelvic hæmorrhage an operation should be undertaken, without waiting for the patient to recover after a lingering convalescence, with the danger of recurrence of hæmorrhage or suppuration. Mr. Moullin advocated waiting for the death of a foetus, when approaching maturity, before operating.

Dr. G. H. DRUMMOND ROBINSON agreed with Mr. Malcolm in his view that operation is not called for in every case of extra-uterine pregnancy in the early stage.

Dr. SEPTIMUS SUNDERLAND asked Mr. Malcolm in what proportion of cases under his notice he has observed that there has been no absence of menstrual flow. In his experience, the menses occurred regularly during the early months of extra-uterine gestation.

Mr. MALCOLM replied to Dr. Septimus Sunderland by saying that he was quite sure that menstruation is not *always* in abeyance until the tube ruptures.

Dr. F. J. McCANN delivered an address (illustrated by a large series of lantern slides) on the "Early Diagnosis of Cancer of the Neck of the Womb." A short description was given of the normal anatomy of the cervix and the importance of the "transitional area"—*i.e.*, where the squamous epithelium covering the vaginal portion joins the columnar epithelium lining the cervical canal—was especially emphasised as the starting

point of malignant growths. The subject was considered under two headings—(1) Cancer affecting the vaginal portion (portio vaginalis); and (2) cancer affecting the cervix proper. This distinction, however, is only possible in early examples of the disease, for the advent of ulceration alters the relationship of the different parts of the cervix. Three clinical types of cancer of the vaginal portion of the cervix occur. (a) The papillomatous or polypoid type, where a sprouting growth extending upwards into the vaginal canal originates by a somewhat broad base from the margin of the external *os uteri*. In this class is included the so-called cauliflower excrescence. (b) The infiltrating type, where the tissue of the vaginal portion is infiltrated with cancerous growth, one or both lips of the cervix being affected. (c) The superficial, flattened type prone to early ulceration. Here the growth creeps over the surface of the vaginal portion, and as there is a tendency to early ulceration a true malignant ulcer in an early stage is seen. Two special types of cancer affecting the cervix proper may be identified. (a) Superficial carcinoma of the mucous membrane of the cervix proper, characterised by the growth of papillomatous masses of different sizes in the interior of the canal, followed later by ulceration changes which hollow out the cervix and produce the characteristic crateriform ulcer, and (b) the infiltrating type where the walls of the cervix are infiltrated in part or in their entirety with cancer. This last type tends to spread rapidly to the lymphatics, and hence is frequently discovered when it is beyond hope of eradication. The early signs of cancerous disease are discharge and hæmorrhage. Discharge is the first sign, but hæmorrhage is the sign which prompts the patient to seek advice. It will be found that careful inquiry into the history of early cases will elicit the fact that an alteration in the quality and quantity of the leucorrhœal discharge is observed before any bleeding has occurred. For this reason all cases of discharges or a typical bleeding should be carefully examined and the *os uteri* inspected through a speculum. The signs elicited on examination are as follows: 1. Friability, a sign of great importance which can be tested by the finger nail, the curette, the uterine sound or a long probe. If there be much fibrous tissue present in the growth, friability may be entirely absent. 2. The occurrence of bleeding, the amount of which is entirely out of proportion to the extent of the injury inflicted. 3. The definite occurrence of new growths from the surface of the cervix, from the lining of the cervical canal, or in the substance of the cervix. The most common pathological changes in the cervix which may be confused with cancer are (1) Erosion. In the common erosion there is no ulceration. It surrounds the *os externum*, the edge is not sharply defined, but fades away into the surrounding mucous membrane. Epithelial islets and plugged follicles may be noted on the surface, and there is no infiltration of the base. (2) Chronic cervical catarrh in elderly multiparæ associated with fissures and hypertrophy of the cervical walls. The examining finger passes into the patulous cervical canal, whose lining is rough and furrowed with thickened, hard, cervical walls. On withdrawing the finger blood may be seen upon it. *Per speculum.* The mucosa of the cervix is smooth, shining, bright red, with total absence of any ulceration. It is only by firm pressure of the finger or sound that bleeding from the surface occurs, and above all, neither the sound nor the sharp curette can detach pieces from the cervical lining. If still in doubt, the microscope can be used.

A full description was given of the different varieties of ulcer met with on the cervix. The differential diagnosis from polypi and small myomata, distended follicles, &c., was given.

Dr. G. R. DRUMMOND ROBINSON pointed out that one of the most reliable signs of early cancer was the presence of friability of the suspected tissues.

Mr. DONALD ARMOUR asked Dr. McCann whether in cancer of the vaginal portion of the cervix he always

performed a pan-hysterectomy or is satisfied with supra-vaginal amputation.

Mr. CECIL H. LEAF wished to know Dr. McCann's opinion as to how much importance he attaches to the presence of ulceration, as he did not consider it a reliable guide.

Dr. McCANN emphasised Dr. Robinson's remarks as to the importance of friability being an early sign, and in reply to Mr. Armour said that he was still in favour of supra-vaginal amputation of the cervix in early cases of cancer affecting the vaginal portion, whilst he preferred hysterectomy for other forms. Dr. McCann, in replying to Mr. Cecil Leaf, said that apart from traumatism, a *genuine* ulcer of the cervix was either malignant, tuberculous or syphilitic, and as the last two were rare, cancer should be suspected.

THE SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.

DR. EDMUND HOBHOUSE (Brighton) in the Chair.
MEETING HELD FRIDAY, FEBRUARY 17TH, 1905, AT
11 CHANDOS STREET, W.

Mr. N. BISHOP HARMAN showed a case of Unilateral Paralysis of the third and fourth cranial nerves, of congenital origin.

Dr. PORTER PARKINSON agreed that it might be due to an anterior poliomyelitis.

Mr. SYDNEY STEPHENSON pointed out that in some cases there was a marked history of heredity.

Dr. E. HOBHOUSE showed a child, æt. 5, with Hemiplegic Spasticity and Inco-ordination on the right side; weakness of the right arm was followed a year later by inco-ordinate movements of the leg; six months before any nervous symptoms appeared the child had convulsions. There was no optic neuritis and no mental impairment. The condition had remained stationary for the last eight months. There was considerable spasticity on the right side and it was almost impossible to obtain a knee-jerk.

Dr. F. PARKES WEBER showed a girl, æt. 12, with Chronic Joint Disease, Splenomegaly and Enlarged Axillary Glands. There had been a definite general reaction to tuberculin, and he regarded this as a valuable indication for treatment.

Dr. F. J. POYNTON showed a boy, æt. 8, with Chronic Arthritis which had begun, without apparent cause, three years before. The affection was most marked in the hands and feet. The course was characterised by relapses and fever, with a good deal of local pain. The axillary glands were enlarged, but no splenic enlargement had been found. Radiography showed no changes in the bones. The appearance of the fingers was that of rheumatoid arthritis.

Dr. EDMUND CAUTLEY showed boy, æt. 9, with early Osteomyelitis or Epiphysitis of the Upper End of the Femur. He was admitted to hospital on December 16th, 1904, as a case of rheumatic fever. The symptoms were pyrexia, leucocytosis, anæmia, unduly frequent pulse, and pain and swelling in the upper part of the left thigh. An exploratory incision on December 28th was negative in result. On January 27th, skiagram showed definite changes in the neck and upper part of the shaft, and in both trochanters. On February 8th, pus appeared under the scar of the exploratory incision and on re-opening the wound a probe passed down to bare bone. Dr. Cautley regarded the case as one of mild osteomyelitis, starting as epiphysitis of the great trochanter.

Mr. DOUGLAS DREW advised further exploration.

Mr. ARTHUR EDMUNDS showed a boy, æt. 7, with Syphilitic Arthritis of the Right Knee, forming a painless swelling, of two years' duration, which had markedly decreased under anti-syphilitic treatment.

Dr. C. A. SUTHERLAND showed a boy, æt. 12, with Syphilitic Arthritis of both Knees, of one month's duration and quite painless. The joints contained free fluid. There was no other evidence of disease. He stated that in his experience drugs had proved of little use and that the affection ran a prolonged course, ending in spontaneous recovery.

Mr. DOUGLAS DREW showed a case of Excision of both Hip-joints for Tuberculous Disease and one of Acquired Club-foot with marked hereditary tendency.

Dr. E. PRITCHARD showed a child, æt. 2, with Spastic Diplegia and Optic Atrophy. The head was microcephalic. Labour was difficult and prolonged. Spastic rigidity was almost universal and almost constant choreiform movements were present in the hands and arms. Frequent mild fits occurred. The first fit was said to have been on the third day of life. There were no signs of intelligence. He regarded the condition as one of microcephalic congenital idiocy due to arrested or perverted development of the nerve elements.

Dr. HOBHOUSE showed a specimen of Congenital Absence of the Gall-Bladder and Bile-Ducts from a female, æt. 8 months, jaundiced since birth. Urine contained no bile salts or pigment. Fæces were white. The liver weighed 8 ozs. and the child 9 lbs. at death. There was marked interlobular cirrhosis.

Dr. HOBHOUSE also read a paper on a case of Interstitial Nephritis, with extensive Renal Retinitis, in a girl, æt. 6. The eye symptoms appeared two months before death, and were very intense. Urine was rather copious, contained a few hyaline casts and blood for a time. There was no evidence of congenital syphilis, but the child had had scarlet fever at the age of three. The kidneys were exhibited.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY. MEETING HELD MARCH 1ST, 1905.

PROF. JOHN CHIENE, C.B., President, in the Chair.

DR. GEORGE THOMAS BEATSON (Glasgow) read a communication entitled "The Etiology of Carcinoma: Does it Perform any Physiological Function When Present in the Human Body?" a full abstract of which will be found in another column under the heading of "Original Communications."

A long discussion ensued on the conclusion of this interesting paper, in which Professor A. R. Simpson, Dr. McBride, Dr. Taylor, Mr. H. J. Stiles, Professor Chiene, Dr. Ritchie, and Dr. Wm. Russell took part.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

A MEETING HELD IN THE MEDICAL SCHOOL, SHEFFIELD,
ON FEBRUARY 17TH, DR. LLOYD ROBERTS, PRESIDENT, IN THE CHAIR.

MULTIPLE PAROVARIAN CYSTS WITH UTERINE FIBROID.

Dr. S. BUCKLEY showed a fibroid the size of a hen's egg, enucleated from the uterus, together with both appendages, removed on account of ovarian pain and enlargement. In close proximity to each ovary there was a cluster of small cysts which were clearly of parovarian origin.

DERMOID CYSTS OF THE OVARY.

Dr. FAVELL showed an ovarian dermoid as large as a seven months pregnant uterus. It presented two well-formed teeth and a mammary gland with a nipple, together with a large quantity of hair. The patient had menstruated regularly, but had suffered pain during the last six months.

Dr. SINCLAIR WHITE showed an ovarian dermoid removed from a girl, æt. 13, who had never menstruated. It was generally adherent and the pedicle was twice twisted.

HÆMORRHAGE NEAR THE MENOPAUSE.

Dr. A. J. WALLACE instanced three cases. The first patient, æt. 50, had a sanguineous discharge for nine months. Cancer of the body was discovered and vaginal hysterectomy was done, facilitated by Schuchardt's vaginal incision. The speaker had been troubled by suppuration in this incision in several cases, and, in two, had seen rapid recurrence of cancer in the scar. The second patient, æt. 53, had ceased to menstruate for four years, when discharge began, and some months later the uterus was removed by the abdominal route,

the vagina being very narrow. The condition was again cancer of the body. The third patient, *æt.* 51, had suffered from menorrhagia for six years. The enlarged uterus at one time reached the umbilicus, but three weeks later was found to be considerably reduced in size, although no mass had been expelled from it. Vaginal hysterectomy was done, the large uterus being delivered by means of free vaginal incisions. The uterine walls were found to be thickened by a layer within, and distinct from, the original uterine wall, composed of fibrous trabeculæ enmeshing masses of muscular tissue.

The PRESIDENT would have preferred the abdominal route in the third case.

Dr. DONALD had given up the use of vaginal incisions in hysterectomy and preferred to reduce the tumour by morcellation.

Dr. GEMMELL had also observed suppuration in Schuchardt's incision and rapid recurrence of cancer in the scar.

ECTOPIC PREGNANCY.

Dr. BUCKLEY showed a thick-walled cyst of the outer portion of the Fallopian tube which contained blood clot, and was lined by a layer of granulation tissue. The diagnosis lay between ectopic pregnancy and hæmatosalpinx of inflammatory origin. The history suggested the former, but no chorionic structures could be found on microscopic examination.

ABDOMINAL MYOMECTOMY FOLLOWED BY PREGNANCY.

Dr. A. DONALD reported the case of a patient, *æt.* 31, on whom he operated for the relief of pain and hæmorrhage. There was a single soft fibro-myoma, as large as a cocoanut, growing from the uterus into the left broad ligament. It was enucleated without opening the uterine cavity, the bed being closed by both buried and superficial sutures. Two years later the patient became pregnant and was naturally delivered in due course of a healthy child.

ANOMALOUS UTERINE TUMOUR.

Dr. DONALD mentioned the case of a woman, *æt.* 40, who had a hard lump in the hypogastrium for two years, which recently caused acute pain and rapidly increased in size. On operation the hard fibroid uterus was found to be surmounted by a softer growth emerging in fan-shaped manner from the fundus. This vascular, deep red tumour proved to be a spindle-celled sarcoma, while the uterine tumour was an ordinary fibro-myoma.

HYSTERECTOMY AT THE SIXTH MONTH OF PREGNANCY.

Dr. FAVELL showed a uterus with sixth month fœtus and containing two large subserous fibroids in the lower uterine segment. The patient was *in extremis* with pressure symptoms, jaundice and albuminuria, when the operation, the only one possible, was performed, and recovered very rapidly.

PRIMARY SARCOMA OF THE OVARY.

Dr. GEMMELL narrated two cases of very malignant and rapidly recurring ovarian sarcoma in young women. The first, *æt.* 17, gave a history of three weeks abdominal pain and swelling. A hard, solid growth reached the costal margin and bulged into the pelvis. It was completely removed, but in three months the patient was readmitted with a large soft recurrence. This affected the mesentery and omentum and was scooped out by hand, but was beginning to reappear a month later. The second patient was *æt.* 20, and complained of two months' pain, wasting and weakness. An abdominal swelling reached above the umbilicus, and there was an irregular mass behind the uterus. On opening the abdomen blood-stained serum escaped, and after removing the ovarian sarcoma, deposits in the pelvis were found which could not be completely extirpated. There was rapid increase in the growth during the patient's recovery from the operation.

NORTH-EAST LONDON CLINICAL SOCIETY.

MEETING HELD THURSDAY, MARCH 2ND, 1905.

Dr. R. MURRAY LESLIE, President, in the Chair.

Mr. A. DE PRENDERVILLE read a paper on some ANÆSTHETIC DIFFICULTIES AND HOW TO COMBAT THEM, which will appear in a future issue.

The PRESIDENT, in congratulating the author, remarked upon the comparative frequency of post-anæsthetic pneumonia, and he considered, in view of the fact that the pneumococcus had been found in about 65 per cent. of healthy mouths, that some of the cases might be due to direct infection from inhalers or to the acquisition of virulent properties of the germ, which flourished in a mucous membrane whose resistance was lowered from the irritation of the anæsthetic.

Mr. ALEC. H. BREWER (introduced) referred to the so-called "chloroform sleep," which might well be classed as an anæsthetic difficulty. He had met with several instances of this condition, which was apt to prove deceptive, for bystanders usually remark that patients in this state "are taking it beautifully," whereas true anæsthesia is seldom present. Children were most often affected in this way by chloroform, the pupil being small and the corneal reflex abolished, but the respiration was not automatic. With regard to the tendency of bronchitis often met with in ether anæsthesia, he had found a combination of oxygen with ether very useful as a prophylactic.

Dr. F. J. TRESILIAN (Enfield) inquired if sudden oedema of the lungs was common after ether, as instanced by Dr. Murrell, and he related an unfortunate experience with somniform in a dental case.

Dr. A. J. WHITING considered that the recent work of Emby and Martin marked an epoch in the progress of anæsthetics. He had been, like many others, brought up in the creed that chloroform was the most convenient anæsthetic, but if it were now a question of having to regulate the percentage of the vapour, it would become altogether a different matter. Indeed, it would almost appear that chloroform should never be used again, in the light of recent research!

Dr. ARTHUR E. GILES thought that the operator should, at least, have some choice in the matter of what anæsthetic should be employed in a given case, but in many instances this was better left absolutely in the hands of the administrator. For his own part, he preferred ether as a routine anæsthetic, as tending to minimise the rise of blood pressure and consequent late hæmorrhage which sometimes followed the administration of chloroform in severe gynæcological operations.

Dr. E. HOOPER MAY recalled the time when there was no other anæsthetic in use but chloroform, and he never saw any bad results ensue from the "bold" method of administration then advocated by the Edinburgh School, even in the dental posture.

Mr. HERBERT CARSON considered that there was an added risk of giving an anæsthetic in the upright position in throat operations, and he referred to the special difficulties encountered in such major operations as those performed for cerebral compression for abscess and for intestinal obstruction. In the former case, the breathing not infrequently stopped quite early in the operation, while in the latter he had known grave risk incurred from the regurgitation of gastric and intestinal contents into the air-passages.

Mr. C. F. HUTT referred to the difficulties met with in anæsthetising patients when in the lithotomy position. As a general rule, he preferred a mixture of chloroform and ether. Mr. DE PRENDERVILLE replied.

France.

[FROM OUR OWN CORRESPONDENT.]

Paris, March 5th, 1905.

INFANTILE BRONCHO-PNEUMONIA.

BRONCHO-PNEUMONIA is a much graver affection than pneumonia in children, generally secondary, as a complication of small-pox, grippe, diphtheria, typhoid fever, or measles. When children are affected by any of these maladies, rigorous antiseptics of the natural orifices should be enjoined. In children of a certain age antiseptics of the nasal fossæ will be obtained by inhalations of—

Menthol, 3 grs. ;

Boric acid, $\frac{1}{2}$ dr.

For one powder, dissolved in an infusion of the leaves

of the eucalyptus tree and inhaled through a funnel. In young children, these inhalations can be replaced by instillations of—

Menthol, 20 grs. ;
Oil of sweet almonds, 2 ozs.

The mouth should be frequently rinsed with a solution of boric acid, and the eyes bathed with the same liquid, while oxygen water reduced to half strength should be instilled into the ears. With such precautions, says Professor Vidal, the lungs may be kept clear of infection.

When in the absence of such prophylactic measures, or in spite of them, broncho-pneumonia does set in, the treatment varies according to the intensity of the disease. If the child is not too depressed a vomitive will clear the large bronchi of mucosity, but if dyspnoea with tendency to cyanosis be present, a teaspoonful of the following mixture every hour should be given:—

Acetate of ammonia, $\frac{1}{2}$ dr. ;
Rum, 4 drs. ;
Syrup of ether, 4 drs. t ;
Water, 3 ozs.

To control the fever cryogenine might be ordered:—

Cryogenine, 20 grs. ;
Rum, 4 drs. ;
Syrup of tolu, 4 drs. ;
Syrup of cinchona, 4 drs. ;
Water, ad 4 ozs.

A dessertspoonful three or four times a day.

Hydrotherapy is one of the best means we have of treating broncho-pneumonia. The wet sheet, warm or cold baths, according to the judgment of the attendant.

The wet sheet might be renewed four or five times a day and left *in situ* for half an hour.

Balneation is recommended by all authors.

Labadie and Lagrave advise cold baths (77° F., and gradually reduced to 64° F.), in which the child is left five or ten minutes, and then rubbed vigorously to produce reaction and finally enveloped in a blanket.

The warm baths, on the other hand, should be given at 100° F., in which the patient remains from ten to fifteen minutes. Cold should be applied to the head while the child is in the bath to prevent cerebral congestion. In cases of collapse, mustard should be put in the bath.

Revolvives consist in mustard poultices and small blisters left on four hours and renewed.

As to a curative method, none has yet been found. Netter appears to have obtained good results from

Collargol, 30 grs. ;
Vaseline, 3 drs. ;
Lanoline, 1 dr.

Rubbed into the axilla or the groin for about fifteen minutes, then wiped off and the place covered with oiled silk.

If at the end of a month or six weeks the patient has not quite recovered, tonic treatment should be ordered and the air cure.

TREATMENT OF ACUTE CORYZA.

Phenic acid, 1 dr. ;
Liq. ammonia, 1 dr. ;
Proof spirit, 2 drs. ;
Water, 4 drs.

Pour 20 drops on blotting paper and breathe the vapours through the nose every hour.

Or—

Boric acid, 1 dr. ;
Menthol, 10 grs. ;
Cocaine, 5 grs. ;
Proof spirit, 5 drops ;
Talc powder, 2 drs.

To be used as snuff.

Iodide of sodium, 1 dr. ;
Syrup of bitter orange, 1 oz. ;
Syrup of lemons, 1 oz. ;
Water, 6 ozs.

A tablespoonful three times a day in milk.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, March 5th, 1905.

At the Society for innere Medizin, Hr. Langstein gave an address on

DIABETES IN CHILDHOOD.

It was a very infrequent occurrence, as he had only seen 8 cases in Heubner's Klinik between April 4th, 1904, and the present. The first case was that of a little girl, *æt.* 1 $\frac{1}{2}$, who had been treated in several polyclinics. The mother said the child had fallen out of bed twice about two months before, and had fallen on her head. Two days later the child seemed tired, and a slight cough came on. There was slight mischief at the apex of one lung, and the temperature was 38.1° C. She also said that the child was very thirsty, and that she drank about 2 $\frac{1}{2}$ litres of milk a day. Sugar was present in the urine. She would not allow the child to remain in hospital, but permitted examination of tissue changes to be made at home. It was ascertained that with the diet of 2 $\frac{1}{2}$ litres of milk the urine amounted to 5 $\frac{1}{2}$ litres, with 7 to 9 per cent. of sugar, together with a large quantity of acetone and acetic acid. In the first four days 200 and 250 grammes of sugar were excreted, and 14 grammes of oxybutyric acid. Butter-milk was given to reduce the quantity of oxybutyric acid, which was, in fact, reduced to 2 to 3 grammes in the 24 hours. As strict dieting was not practicable, oatmeal was substituted for the carbohydrates, and the quantity of sugar fell to 70 to 80 grammes, but the reduction could not be carried further. The child died of diabetic coma. The quantity of ammonia excreted was very large, 45 per cent. of the whole nitrogen consisting of it.

The second case was that of a child, *æt.* 3 $\frac{1}{2}$. There was no history except that after a fall on the head it had become sleepy and dull, and that since that time it had suffered from hunger and thirst. The urine excreted was 3 to 4 litres daily, containing 5 per cent. of sugar, and acetone and acetic acid. Here, also, oatmeal was given with good results so far that it again became lively and played. The hunger, however, continued so that the child used to go round to the neighbours to beg bread. Three and a half months later it also died in diabetic coma. There was no heredity in either case.

The next cases were not so carefully examined. They were two children, *æt.* 5. The thirst and hunger were relieved by the oatmeal diet, but they died in diabetic coma. Another child, *æt.* 7, had 4 per cent. of sugar in the urine; he died in 4 $\frac{1}{2}$ months. One case was interesting as showing heredity. The father died of diabetes, *æt.* 32, a sister also died of the disease *æt.* 5. The proportion of sugar was 2 per cent. Without any special diet the quantity of urine fell, and it contained no sugar. On the 5th, afterwards, 2 per cent. of sugar was again excreted; it then disappeared, and since then had not reappeared.

In one case recovery was observed. A little girl, *æt.* 7, was admitted suffering from thirst. There was no trace of injury or heredity. The quantity of sugar was always from 1 to 2 per cent. Then 100 to 150 grammes of oatmeal were given, and the proportion of sugar gradually fell to 0.4 and 0.1 per cent. In the last fortnight no sugar had been excreted, although carbohydrates had been given.

In one case observed by a friend the child took pneumonia when the sugar disappeared and it did not return. The disease was not always easy to diagnose in infancy. The ordinary tests were not trustworthy, the only certain one being Fischer's. There was a condition in infancy that simulated diabetes, *viz.*, enterocatarrh. Here, with a milk diet, sugar was always found in the urine in large quantities, but it was not grape sugar, but sugar of milk; it was lacturia, and not glycosuria. Milk fat was to be looked upon as the source of the acetone.

As regarded treatment, the speaker had acquired the impression that oatmeal could be given with advantage

when the other carbohydrates increased the quantity of sugar.

Hr. Litten saw a number of cases in 1880 that gave the impression of diabetic coma, but there was no sugar in the urine, only acetone and acetic acid. He had described these as cases of coma dyspepticum. Cataract developed with enormous rapidity in infantile diabetes.

Hr. Magnus-Levy said infantile diabetes was very fatal and generally quickly so. He wished to know if, in order to avoid the formation of oxybutyric acid, when the fat in the food was limited as much as possible and carbohydrates withheld entirely and albumen partially, what was to be given? The assumption that when more fat was given more oxybutyric acid was formed was not a correct one.

Hr. Mohr had had very good results with oatmeal treatment of diabetes, but it was of importance to give no other carbohydrates at the same time. His cases increased in weight under the diet. His experiments showed that albumen participated in the formation of sugar. Acetonuria occurred under various conditions. One cause was the too strict withholding of carbohydrates.

Hr. Huschfeld said that Fischer's test for sugar was too searching; it even showed traces of sugar in healthy people. Too much buttermilk should not be given as a sufficiency of fat was thereby excluded. He had seen both good and bad results from oatmeal treatment, but it ought to be tried. As regarded heredity, it was not always connected with diabetes amongst relatives, but it was not infrequently related to psychic affections.

Hr. Heubner remarked that Litten's dyspeptic coma was not identical with that of entero-catarrh. The one was easily curable, the other was always a symptom of serious poisoning, and the prognosis was always unfavourable.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, March 6th, 1905.

HYDROCYSTOMA.

At the Gesellschaft Riehl exhibited a female, *æt.* 56, with what he designated Robinson's disease, having been first described by this author in 1886 as a distinct skin affection under the name of hydrocystoma.

The patient suffered from unilateral facial hyperidrosis along with the uncommon condition of diffuse cysts which anatomically depend upon a pathological dilatation of the sudatory ducts. He thought the true etiology of the disease depended on an altered state of the gland or functional activity.

This view, he maintained, was supported by its occurrence on the face in washer-women, who were exposed to steam and heat that would excite the disease. The malady soon subsides without any bad effects.

CHOLELITHIASIS.

Bakes demonstrated a few preparations which he had taken from sixteen operations for cholelithiasis. The chief principle of his treatment was to operate at the earliest opportunity as soon as the pathological changes in the gall-duct were recognised, that all concretions should be carefully removed and adhesions separated to avoid any abnormal communications, and that drainage and tampons should be carefully carried out. He advises operation in all chronic closures of the chole-dochus, but acute forms of the disease should be avoided. The hepatic drainage apparatus of Kehrs is an essential equipment for all gall-duct surgery.

RADIO-ACTIVITY OF THE GASTEIN THERMAL BATHS.

Mache gave the members a long description of the beneficial effects obtained from the thermal waters in Gastein, which have recently been under discussion at the Kaiserlichen Akademie of Science. In this water it has been discovered that the emanations of radium are the chief virtues of the bath. In the discussion that followed Neusser was of opinion that Gastein water could be artificially prepared. He had himself obtained Urana pitch-blende from Joachimstal

in Bohemia, and produced a similar radio-active water. According to the analysis of the Gastein water the presence of this substance is found to be 0.000496 grms. in weight. Now, if five kilogrammes of this Urana pitch-blende be so spread over a bath that its emanations can be utilised, the therapeutic radium effect of Gastein water can be obtained. This same substance, pitch-blende, can be applied in the form of stupes or poultices by wrapping the pitch-blende in pieces of cloth. He had applied the substance in this form to two severe cases of tuberculous peritonitis with perfect success in relieving pain and rapidly absorbing the exudation. In another case of intercostal neuralgia he records a similar happy result. It may not be well known to all the members that in Joachimstal rheumatism is supposed to be charmed by this water, and certainly it produces a very happy result in those affected.

Urick said that the waters of Gastein did not of themselves contain all these virtues, as the surroundings, elevation, climatic changes, temperature of bath with the other constituents of the water, with, no doubt, a little suggestive treatment, were all beneficial factors in the curing of the disease. He quite concurred with Neusser in his artificial results. He had personally treated 3,000 cases at Gastein with only 10 per cent. of reactionary phenomena. These activities might be summarised as increased pain in the tabetic and neurasthenic, with disturbance of the sensorium, cardia and menstruation. Aggravation of the disease or skin eruptions were rarely to be observed. In all these disturbed cases he could not specifically point to radium emanations as the real cause, but would not at the present time venture to deny that such existed, as the thermal effects of the water can be identified with the results obtained from radium emanations.

LYMPHATIC LEUCOCYTHÆMIA.

Gerber showed a case of leucocythæmia which he had treated with Röntgen rays with perfect success. The rays were applied directly to the swollen lymphatics which rapidly subsided, and at the same time the number of leucocytes in the blood were gradually reduced. The only explanation that can be given is that the rays immediately check the formation of the lymphatic cells in the glands. The effect is not slow and gradual on the blood, but rapid and can be observed a few hours after application.

Holzknrecht remarked that he could confirm Gerber's observation from eleven cases which he had treated in a similar manner. Besides these cases mentioned he only knew of twelve others in the literature of the subject. There is another case recorded of myeloid lymphatic leucocythæmia with an upward curve of leucocytes at the beginning of the treatment which subsequently fell to a subnormal condition.

The Operating Theatres.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.

PIECE OF STEEL INSIDE THE EYE REMOVED BY MEANS OF HAAB'S ELECTRO-MAGNET.—Mr. H. WORK DODD operated on a man, *æt.* 26, an engraver from Woolwich Arsenal, who had been admitted to the hospital suffering from an injury to the right eye. The patient stated that, whilst working, a piece of steel flew up and hit him on the upper lid. On admission, there was a wound in the upper lid at the junction of the middle and nasal thirds, about six millimetres from the ciliary border; on everting the upper lid a corresponding wound was found on the conjunctival surface. There was also a wound in the eyeball corresponding in position to the wound in the lid, situated four or five millimetres from the corneo-scleral junction. This, Mr. Dodd pointed out, seemed to indicate that the foreign body had consider-

able force and velocity to penetrate through the thickness of the lid with its cartilage, the conjunctiva, and the sclera. The wounds were all about the size of a small pin's head. When the house surgeon first saw the case, some three or four hours before the operation, blood was, on ophthalmoscopic examination, beginning to be poured into the vitreous chamber, and he fancied he could see something which might have been the foreign body situated in the upper and inner region of the vitreous chamber. When Mr. Dodd examined the eye with the ophthalmoscope, the eye was too full of blood to allow any details to be seen; the lens appeared to be clear and normal. In view of the history being so definite, he thought that he might try the effect of Haab's big electro-magnet. This magnet, situated on a kind of heavy wooden table, is about a foot and a half long and six or eight inches in diameter. It appears to be composed of coils of wire tapering off into metallic cones at each end, and is of great weight. It rotates horizontally easily on a hinge so as to move in any direction, and is connected with the electric power of the hospital, the application of this last being controlled by a pedal apparatus. The magnet is evidently one of great power, as a bunch of keys thrown a few inches from it is immediately seized and brought into contact with it, and it is necessary, as Mr. Dodd remarked, for the surgeon and his assistants to leave their watches outside the room, otherwise the watches would certainly be thrown out of order by the magnetic current. The patient was seated on a stool which could be raised or lowered so as to bring his eye opposite and close to the cone apex. The magnet was first applied several times to the wound in the sclera, but this proved to be ineffectual. The patient was then told to look directly at the cone, the eye being brought almost in contact with the instrument. As the foreign body had appeared to lie in the upper and outer part of the vitreous chamber. Mr. Dodd thought that it might be brought forward into the anterior chamber by this means. The eye being in this position, the power was several times taken off and then applied suddenly, so as to move the foreign body by jerks, if possible; after this had been repeatedly done, Mr. Dodd pointed out that the iris bulged forward at a point corresponding to its upper and inner quadrant. The magnet being next re-applied, the iris protruded again at a lower point, showing that the foreign body was gravitating to the inferior part of the eye. By moving the eye in various directions Mr. Dodd now hoped to bring the foreign body out through the pupil into the anterior chamber, but this he was unable to do, as the foreign body seemed to catch itself at the back of the iris at the lower and inner quadrant, and there could be seen trying to force its way, whenever the current was applied through the base of the iris. At this stage, the patient, still being in proximity with the acting magnet so as to hold the foreign body in its present position, after cocaine had been applied to the conjunctiva, Mr. Dodd made an incision into the corneo-scleral margin as near as possible to the foreign body. The iris then showed a tendency to protrude through the wound, being pushed forward by the foreign body; therefore Mr. Dodd, with a broad, sharp needle, made a hole through the base of the iris on to the foreign body, which last he had the satisfaction to see come forth on to the cone of the magnet, leaving a small piece of

iris protruding from the wound; this was immediately restored to its proper position by means of a blunt probe. The foreign body proved to be a flat, triangular, thorn-shaped piece of steel just under half a centimetre long, its base being about two millimetres in width. The patient behaved admirably all through this trying ordeal. Mr. Dodd said that this was particularly satisfactory, as, considering that if the foreign body had not been found and removed in this way, the patient must undoubtedly have lost his eyeball; in fact, in the old days, before this magnet was introduced into ophthalmic surgery, the eyeball would have been removed at once by the surgeon, for the extraction of the foreign body by any other means would have been practically hopeless. He pointed out that the penetrating wound was unfortunately in the region of the ciliary body, really in the middle of it—that is, it was situated in the so-called dangerous area—and all ophthalmic surgeons know that penetrating wounds in the "dangerous area" were apt to lead to trouble in the way of cyclitis, septic inflammation, and even on to sympathetic iritis of the other eye, so that, although this present operation had been successful as far as the removal of the cause, *i.e.*, the foreign body, was concerned, the patient was a long way from being as yet out of the wood. In his favour was the fact that this foreign body was clean—practically aseptic—being in all probability a portion of a polished tool, and, again, as, having passed through the whole thickness of the lid and its cartilage, the conjunctiva and the sclera, &c., it had been to all intents and purposes wiped and cleansed *en route* before arriving at the interior of the eye. With regard to the application of the magnet, he had always been under the impression that it had been generally found easier to endeavour to remove a foreign body by bringing it from the back of the eye to the anterior chamber, and then making an incision and finally extracting it through the incision, than to endeavour to enlarge the original wound and to try to bring the foreign body out through its point of entry. This impression, he said, seemed to be amply corroborated by the present case. He would have been better pleased, however, if he could have brought the foreign body in this case through the pupil instead of having to make a wound through the iris. The route of the foreign body, influenced by the magnet, was, he thought, peculiar, as one would think the shortest way for it was through the centre of the lens instead of round through the peridental space, the probable explanation of this being that it followed the direction of least resistance—sliding off the curved back of the lens and coming round its edge through the suspensory ligament into the anterior chamber. The reason that it caught in the iris was probably due to the thorn-like shape of the foreign body, which caused it to entangle itself in the meshes of the back of the iris. Mr. Dodd casually mentioned that three brief excellent articles on the subject by Haab, Snell, and another could be found in the last number of the *Ophthalmoscope*.

A fortnight after operation the patient was discharged cured, the vision six-ninths, the eye perfectly quiet, and only a little deformity to be seen, the wound at the base of the iris having healed.

An Epidemic of Measles.

NOTTINGHAM is suffering from a scourge of measles. The exact number of sufferers is not known, but it is certain that some hundreds of children are affected, and the virulence of the epidemic is shown by the alarming mortality. The last week in February there were fifteen deaths, and during the past seven weeks there have been eighty-two deaths.

WEDNESDAY, MARCH 8, 1905.

TYPHUS FEVER IN LONDON.

THE recent outbreak of typhus fever in the East End of London comes as a sharp reminder that infection dies hard. So far as London is concerned, the disease in question has become so rare that a case of it has never been seen by the majority of medical practitioners of the present generation. The malady is admittedly one of the most infectious known to science, comparable only with the subtlety and virulence shown by scarlet fever and small-pox. It is therefore important to draw the attention of medical men in London and elsewhere in the United Kingdom to the fact that at any moment cases of typhus fever may come under their care in guises that may throw the unwary off their guard. Needless to say, the results of undetected and consequently exposed typhus fever may be far-reaching and disastrous. Experience shows that typhus fever, apart from a history of specific infection, is often diagnosed as pneumonia, enteric fever, delirium tremens, and other acute conditions. Mistakes of the kind, in point of fact, were committed in the early days of the present London outbreak. The fact that such errors occurred under the care of highly qualified hospital staffs shows that it is practically impossible always to detect sporadic cases of typhus fever on their first appearance in a community. The whole subject is one of vital importance, not less to the medical profession, who have reputations to save, than to the public whose lives it is the duty of sanitary science to protect. Typhus fever, at one time endemic in all parts of the United Kingdom, has for some time past been practically banished from Great Britain, although it has never lost its footing in Ireland. From time to time cases of the disease are reported in Liverpool, Edinburgh and Glasgow, as well as in other large towns in which there is a large poor population, especially when containing a number of Irish.

It is peculiarly interesting at the present time to read a well-recorded history of typhus infection in the metropolis. Such a record will be found in another part of the present issue of THE MEDICAL PRESS AND CIRCULAR (page 235). It originally appeared in the year 1899, in the form of a report presented by Dr. F. J. Waldo, as medical officer of health to the Vestry of St. George-the-Martyr, Southwark. A case of typhus fever was notified to him on February 20th, 1899, and it occurred to him that there might be a possible connection between that particular case and two previous cases in the district, the one in April and the other in October, 1898. Dr. Waldo accordingly instituted a set of painstaking and laborious investigations. The result was a brilliant vindication of the methods of modern expert sanitary science. He was enabled to trace the connection of the whole series of cases, which were linked in one long, though often tortuous and irregular chain of direct and indirect infection by exposure. The cases were treated both by private practitioners and in public hospitals. Cases and deaths were attributed to enteric fever, pneumonia, delirium tremens and other maladies. It was only at the end of several months that the death of a patient with the "mulberry" rash fully developed aroused a suspicion as to the real state of affairs, if we remember aright the circumstances made public at the time. Among the points emphasised by Dr. Waldo's report may be mentioned the following as specially worthy of notice:—First the fact that he was enabled to trace the missing links of his cases by the courtesy of the medical officers of health in neighbouring districts. Community of action between local sanitary authorities undoubtedly furnishes the key to much that is vital in the future of public health administration. It is of little use to notify and control typhus fever in, say, half a dozen London districts, if in the nearest half-dozen adjacent or overlapping districts nothing is known of the facts and the necessities of the case. So far as other points are concerned, it would be difficult to imagine a document more calculated to put medical officers more on their guard as to the pregnant possibilities of erroneous diagnosis. It has been said of the present outbreak of typhus fever in the East End that there is little danger to be apprehended from the exposure of patients suffering from the disease in hospitals and elsewhere. It is difficult to understand how any such statement could have crept into any responsible lay journal. From the scientific point of view, typhus is one of the most deadly and elusive of the pestilences that stalk by noon-day through the crowded thoroughfares of modern civilisation.

TEACHING HOSPITALS AND MEDICAL SCHOOLS.

THE report of Sir Edward Fry, Lord Welby, and the Bishop of Stepney on the financial relationship of teaching hospitals to their medical schools is bound to mark an important departure in medical education. This "committee of

three" was, it will be remembered, appointed by the Prince of Wales, as President of King Edward's Hospital Fund for London, to answer definitely the allegations made that money subscribed for the relief of the sick poor was used by certain hospital managers to subsidise medical education. The questions put to them were three in number—whether any, and if any, how much, of such money was so employed; whether any return for such contributions was received by the hospitals from the schools; and whether any hospital paying contributions in excess of actual value received from the school was justified in doing so by any special considerations. To these questions the committee replies that in 1903 University and King's College Hospitals paid no such sums to their schools; that Guy's and the Royal Free can hardly be said to have done so; but that the remaining eight of the large hospitals all contributed something to their schools. The second point is answered by saying that although the hospitals receive considerable benefits from their schools, the students, on the other hand, receive a proportionate return by being allowed to use the hospital as a "clinical laboratory," and that these mutual advantages practically balance each other. Any contribution in money from the hospital to the school, therefore, should not, in equity, be required of the hospital. Finally, they find no justification for any special excess of contribution over return. With these conclusions it will, we think, be hard to quarrel, and they contrast unfavourably with the reply put into Lord Knollys' mouth eight years ago, when Mr. Stephen Coleridge inquired of the Prince of Wales' Fund (as it then was) whether any part of that Fund would find its way into the coffers of the schools. Lord Knollys, relying on the information vouchsafed to him, answered that inquiry by saying it was not the intention of the Fund that any part of its donations was to go to the support of any medical laboratory. Medical laboratory is a difficult term to define exactly, but the clear meaning of the phrase is that no subsidy would go to the support of the purely scientific as opposed to the rigidly practical demands of the "clinical laboratory." On the face of it it must be difficult candidly to reconcile this statement and the finding of the Committee, and this inconsistency will put a powerful lever into the hands of the party whom Mr. Coleridge leads. It will be exceedingly regrettable if there is any suspicion of disingenuousness about the information supplied to the authorities of the Fund, and we hope the matter will be promptly and fully cleared up. What is clear to medical men, namely, that hospital work begins in the wards, is continued in the laboratory, and is by the necessities of the case, often completed in the *post-mortem* room—will not be clear to lay people, and donations from the hospital funds to the school funds will not be read in the light of a strict *quid pro quo*. The Committee, we think, put its finger accurately on the weak spot in the matter when it spoke of the attempt of

each of the twelve large hospitals to maintain a completely-equipped school in connection with itself. The day has long passed since a lecture theatre, a dissecting-room, and a museum supplied the essentials of a medical school. The modern school that would provide a complete medical curriculum must have laboratories on a large scale for every department of teaching, and each laboratory must be furnished with elaborate and extensive plant for its own special work. To keep up with the times the medical schools in the Metropolis have been laying out money year after year in their endeavour to supply sufficient attractions for students, and it is an open secret that several of the smaller schools are only maintained by the lecturers foregoing all remuneration, and even in some cases putting their hands in their pockets to meet deficits. This game of beggar-my-neighbour obviously must eventually involve the financially weaker brethren in bankruptcy unless the schools are relieved of some part of their burdens, and the temporary expedient of the hospital managers contributing towards the cost of the schools could only be a temporary expedient. It is characteristic of the heterogeneity of the elements composing the "hub of the Empire" that London, with its unrivalled wealth of clinical material, should remain the worst organised centre of medical instruction. The Committee rightly and properly advise that the insolvency of the medical schools shall be met, not by contributions from the hospital funds, but by the formation of a central institution with every requisite appliance where the preliminary medical subjects should be taught, and that the existing medical schools shall become places where only the last two or three years of the student's course are spent—clinical schools, that is, with the hospitals as clinical laboratories. The London University scheme to this end seems to be faring but poorly, but it is much to be hoped that it will not fall through, for in it, or in some similar arrangement, lies the only true solution of the problem.

Notes on Current Topics.

The Lincoln Typhoid Epidemic.

AT the end of last week the number of cases of enteric fever in Lincoln was over 700 and the outbreak showed no signs of abating. There has naturally been a good deal of excitement and alarm among the governing authorities of the town who have been sitting in secret conclave, and who appear to have even now formed no practical plan of dealing with the polluted drinking water which has brought this terrible disaster upon the good folk of the ancient city in question. Matters will not be mended by vacillation in the present crisis. On February 22nd, in a leading article devoted to the subject, THE MEDICAL PRESS AND CIRCULAR pointed out the only means known to sanitary science of forthwith purifying the water of Lincoln. Hitherto there has been no intimation on the part of the local journals, so far as we

have been able to ascertain, that the plan mentioned has been considered by the Council. The method is that of rapid sterilisation by the Salvator apparatus, which is known as the Vaillard-Desmaroux system in France, where it is extensively used both in civil and in military life. The Japanese, ever certain in their grasp of what is best in our Western civilisation, have no less than fifteen "Salvators" with their army in the field. It can deal cheaply, rapidly, and effectively with the water supply of any town of whatever size. As pointed out by a correspondent last week, the water supply of Lincoln could thereby be rendered safe within ten days. The Council will enormously multiply their responsibility if they neglect the repeated advice we have considered it our duty to offer.

Fine for Incorrect Diagnosis.

WE learn from the *Liverpool Journal of Commerce* that a good deal of concern is being felt by shipowners and shipmasters at the action of the stipendiary magistrate of that city in fining the master of a merchant vessel for concealing a case of plague. It would appear that the *Crewe Hall*, the ship in question, sailed from Rangoon with a clean bill of health, and as she had no illness on board, experienced no difficulty in getting *pratique* at all the ports touched at on the homeward voyage. When the colder latitudes were reached the Lascars, who composed the crew, suffered from the minor ailments which natives of warm countries experience when subjected to lower temperatures than they are accustomed to. Before arriving at Liverpool one of these Lascars had what appeared to be a feverish cold, but no significance was attached to it, and the master reported to the port officials that he had no illness on board. Now it is contended on his behalf that he meant there was no illness as touched on by the regulations, and that he himself attributed no weight to one sailor being out of sorts. The case, however, turned out to be plague; the man died, and the captain was fined £10 and costs for not answering truly the questions put to him under the twenty-third article of the Local Government Board Regulations as to cholera, yellow fever, and plague. It seems that in the book of diseases issued to the masters of ships the incubation period is given as a few days, and that, therefore, it is absurd to suppose that the captain could, in this case, have suspected plague after he had been at sea for many weeks. On the facts as stated we confess to some little sympathy for the errant skipper; if medical men were fined each time they made an incorrect diagnosis we suspect we should not hear so many lamentations over the over-crowding of the profession.

Ventilation of the House of Commons.

THE ventilation of the House of Commons has long been the subject of complaint among our legislators, and a report dealing with it has just been presented to the First Commissioner of Works. It is the result of careful work conducted by Dr.

Gordon, Dr. Huntley, and Dr. Aitken during last session. The report recommends that the air-inlet should be raised and widened—if possible without interfering with façade—and that traffic over the north inlet should cease. The moistening spray that is used to purify the air should, the investigators think, be used regularly instead of occasionally; the doors between the ventilating fan and the inlet be removed or made air-tight; traffic across the air-way prohibited while the House is sitting; pans of water or wet mats provided over the heating apparatus; and the steam-pipes be covered with asbestos. Listerian methods also are suggested to keep bacteria in check. The attendants between the air-inlet and the floor of the House are to be clothed in white linen or drill. Members are to be careful to clean their boots, and hair-matting, as being more easily sterilised, substituted for the string-matting that now covers the floors. It is recommended also that careful hygrometric, thermal, and similar observations should be kept, so that the effect of the various measures may be watched and checked. We hope that all these precautions may be beneficial to the health of our representatives, and that the inertia that they complain of as overcoming them after sitting for some hours in the House may now give way to healthy activity of the neurons. But we do not anticipate that any very satisfactory result will be arrived at, even by these elaborate measures. Fresh air is fresh air, and its stimulating and exhilarating properties cannot be obtained by any amount of moistening, heating, and filtration. Air that is fresh is fresh because it is fresh, and not because it has been treated by any artificial process. Unless, therefore, the wisdom of the Lower House can devise some means for opening the windows of the Chamber, we fear they are not likely to be able to reproduce the atmospheric delights of the Matterhorn in a confined chamber at Westminster.

A Surgeon's Visit to Thibet.

OF some interest at present, in view of the recent expedition, is the account published as long ago as 1789 by Mr. Robert Saunders, surgeon, of Boglspoor, in Bengal, of his observations during a visit to Thibet. It would seem that then, as now, the climate offered the most serious obstacle to the explorer. Among the British forces last year the greatest losses were due to frost-bite; and of the cold winds experienced by him, Mr. Saunders reported that according to native accounts exposure to them caused the loss of the front teeth—certainly an emphatic way of expressing their extreme rigour. As in many other mountainous districts, goitre was extremely common, both in Thibet and Bhutan, and Mr. Saunders makes some interesting suggestions as to its causation, giving good grounds for the repudiation of the snow-water doctrine then fashionable. Syphilis, too, was extremely common, and of a virulent type. Mercuric treatment was in everyday use, being persisted in until the patient was thoroughly salivated for ten or twelve days. The

great terror of the people was small-pox, and when a case occurred the patient was entirely isolated, often being allowed to starve. The house or village was afterwards erased, and thus a spread of the disease was rare. The surgery of the Thibetans was very crude, but their therapeutics were advanced and complex. The vegetable world supplied an infinity of drugs—mostly carminatives, aromatics, and vegetable bitters. Purgatives were imported from China, and emetics were unknown until Mr. Saunders introduced ipecacuanha.

Registrar-General's Report.

THE Registrar-General's report for 1903 is as full of interesting features as usual. The immediately striking items that arrest the attention are the continued fall in the three rates—birth, death, and marriage. To take the last first, it is not perhaps of much significance that a slight decline, .1 per 1,000, below the average of the preceding decennium should have occurred, and it is probably a reflection of a slight depression in trade, the co-relation of marriage with trade being notoriously intimate. The birth-rate continues to show the same downward tendency that has characterised it since the prosperous days of the mid-seventies, and with the arguments founded on this fall in births still fresh in our readers' minds we need not enlarge upon the meaning different parties will attach to it. The declining death-rate, however, must be a cause of unqualified satisfaction to all workers in the cause of hygiene, and we note that the rate for England and Wales, namely, 15.4 per 1,000, is the lowest yet recorded. In the last fifty years this reduction has been constant, and since 1854 there is a difference of no less than 8.1. The significance of this factor is enhanced by the coincident reduction in infant mortality and in deaths from consumption. The former shows a drop of 20 per 1,000 births from the average for 1893-1902, and the latter are but three-fifths of what they were twenty-five years ago. The zymotic death-rate as a measure of the health of a community pales before these two factors, pregnant as they are of improved conditions of living. The only infectious disease that deserves to rank with consumption as an indication of improved sanitation is enteric fever, and this disease in 1903 only accounted for 100 deaths per 1,000,000 living, as against 1,124 from pneumonia, 274 from measles, 189 from influenza, 182 from diphtheria, and 125 from scarlet fever. The whole report, if we exclude the question of birth-rate, is one of happy augury.

Researches in Leprosy.

CAPTAIN ROST, I.M.S., has been engaged during the past two or three years in researches into the bacteriology of leprosy, and has arrived at conclusions which will, if supported, cause remarkable advances in our knowledge of that disease. Though most inquirers are of opinion that the *Bacillus lepræ* which is always found in the lesions of leprosy is the causative organism, yet all at-

tempts at its cultivation have hitherto failed, and consequently the necessary proof of its connection with the disease was not complete. Captain Rost, reflecting on the well-known fact that certain organisms cannot grow in the presence of oxygen, thought that possibly the growth of other classes might be inhibited by the presence of certain other elements. On investigation, he came to the conclusion that the difficulty always experienced in the cultivation of the acid-fast organisms, to which class the *Bacillus lepræ* belongs, was due to the presence of chlorine in the culture media. By obtaining, with considerable difficulty, culture media free from chlorides, he was able to grow tubercle, leprosy, and the other acid-fast bacilli with ease. The *Bacillus lepræ* forms in fluid media a thick deposit, which, on shaking, appears as a curly, white, stringy fluff. On solid media it forms a growth like that of the tubercle bacillus, but turning yellow or red. These results are in themselves of prime importance, but Captain Rost claims to have gone further. Having kept the cultures growing for six weeks, he carefully filtered them, reduced the bulk of the fluid, and used it as an injection in the treatment of leprosy. He claims that one or two injections are sufficient to restore sensation to the anæsthetic patches, and that a more prolonged treatment causes alleviation of pain, resolution of the nodules, and healing of the ulcers. In no case has injection failed to produce improvement. We understand that Captain Rost's serum is at present under trial by many hands in different parts of India, so that we are likely to hear further of it in the near future. Until the reports of these investigators, both clinical and experimental, are made known, one cannot express any opinion as to the true value of Captain Rost's investigations.

Treatment of Consumption in Ireland.

THE history of the Royal National Hospital for Consumption for Ireland, though short, has been one of uninterrupted progress. It is nine years within a few days since a hospital for consumption, with twenty-four beds, was opened by the Marchioness of Zetland, near Newcastle, in one of the prettiest parts of the County Wicklow. To-day it stands fully equipped with one hundred beds, thereby completing the original scheme of the promoters. The Board of Governors has wisely decided not to attempt, at any rate for the present, any further extension on the present lines, but rather to devote themselves, if they are at liberty to extend their work in any direction, to widening the scope of the institution. In particular, the need is felt, as was pointed out eighteen months ago by our Commissioner, of an out-patient department in the City of Dublin where past patients might attend for advice and treatment. One of the chief difficulties sanatorium treatment has to contend with is that of maintaining a hygienic mode of life once the patient has returned to his ordinary surroundings. The number of patients treated in 1904 was 372, that in the previous year being 329; we are glad to notice that the governors

are therefore availing themselves of their increased accommodation rather by giving each patient a longer stay in the hospital than by largely increasing the number treated. We have always held that it is wiser to succeed in producing a permanent improvement in a comparatively small number of patients than to cause slight but temporary improvement in a larger number. The statistics of the Newcastle Hospital are of more than ordinary value, as their compilation since the opening of the hospital has been in the hands of the same resident physician, Dr. Steede; they have thus a greater uniformity than those of many public sanatoria.

John Hunter.

ALTHOUGH Mr. Tweedy, in his Hunterian Oration, wisely made no attempt to add any new facts to our knowledge of the life of the great surgeon, yet by his broad and philosophic appreciation he has given us a better grasp of his mind and work. When Mr. Tweedy remarks that "the greatest men are estimated by the influence they exert upon the thoughts and activities of those who follow them," he claims for Hunter a place among the very greatest, for to him, more than to any one other man, is due the founding of medicine and surgery on a true basis of science. It is not to be understood that there were no scientific surgeons before Hunter, but there is none who stands forth in the same way as the father of modern surgical science. The collection of the magnificent museum which bears his name is perhaps the least of his works, though that alone would be sufficient to place him among the immortals. His great merit was his method, or, to put it subjectively, his mental attitude. He constantly sought for principles, and never remained content with mere facts. On the other hand, he did not proceed, by Baconian rule of thumb, from facts to *axiomata minora*, and thence through *axiomata media* to *axiomata generalissima*, for as Mr. Tweedy rightly points out, no discovery ever was, or ever can be made by strict Baconian methods. Hunter, like all the great men, made discoveries, as it has been called, "by chance," but it is only to the great men such chances occur. In other words, he proceeded by hypothesis, and his greatness is no less shown by his rigid restraint in the testing and rejection of unsatisfactory hypotheses than by his fertile ingenuity in inventing them. To a student who drew attention to some expression of opinion at variance with his previous teaching, he replied, "I hope I grow wiser every year. Never ask me what I have said, or what I have written; but if you will ask me what my present opinions are I will tell you."

Medical Practice in Siberia.

IF it were for nothing but its vastness, Siberia has for most minds a curious fascination. Recent events have, moreover, given it an additional interest which renders all the more attractive anything that helps to bring home to us the life of its people. Dr. Hassim, now of Chicago, but formerly for some years a practitioner of the dis-

trict of Yenesseysk, contributes to a recent number of the *Journal of the American Medical Association* a description of the conditions of medical practice in Siberia, which gives us an appalling picture of the lack of medical attention from which the people suffer. The towns, it is true, are well supplied with medical men; in Krasnayarsk, for instance, to a population of 30,000, there were twenty-four medical men, and in Yenesseysk, to a population of 10,000, there were seven. Many of these are in Government employ for special duty, and do not undertake private practice. The towns, however, are small and far apart, and the intervening country is practically devoid of medical attention in sickness. The province of Yenesseysk, which contains about 1,000,000 square miles, was, until a few years ago, divided into six districts, to each of which two medical men were allotted, one of whom, however, performed only medico-legal duties. These physicians lived altogether in the towns, and only visited the country parts of their districts once a year, and occasionally during epidemics. Even in the latter case they did little more than travel from one village to another and record the number of sick. Dr. Hassim had himself to travel eight hundred miles during a bad epidemic of typhoid fever, but rarely was able to spend more than an hour or two in each village. The very unhygienic conditions under which the peasants live are responsible for an unhealthy condition of the population with which obviously there is no attempt to cope.

Varicocele Among Recruits.

AMONG the various minor ailments which are the bane of male adolescence, varicocele is by no means the least important. The aching pain to which it gives rise when fully developed is quite sufficient to prevent the sufferer therefrom from taking part in any occupation involving much standing, walking, or other physical exertion. Teachers of surgical anatomy are always most careful to impress upon students the fact that the condition is more common upon the left side, owing to the mode in which the left spermatic veins empty themselves into the renal vein upon the same side. To army surgeons varicocele is of considerable interest, owing to the disability which it causes among soldiers. As a matter of fact, the rejection-rate among recruits is fourteen per thousand from this cause alone, while 2½ per cent. are supposed to be suffering from this affection in more or less degree. The success which has attended Bennett's operation for the radical cure of varicocele has enabled many men to lead useful lives who would otherwise have been wholly incapacitated from active service. Major S. G. Allen finds that in 1903 the number of cases of varicocele operated upon in the Royal Herbert Hospital, Woolwich, was second only to that undertaken for the radical cure of hernia, it being understood, of course, that only bad cases of the disease are admitted. Minor degrees of the affection must be far more frequent, and of these no series of statistics are

forthcoming. The fatigue and physical exhaustion attendant upon forced marches would be felt to a greater extent by a man who has but a slight varicocele than by the individual whose pampiniform plexus is normal.

Water-Drinking in Typhoid Fever.

It is difficult to resist the impression that febrile states demand a more copious flushing, as it were, of the excretory channels than normally takes place. A feverish patient instinctively craves for an abundance of cooling liquid, and no matter whether this be merely water or some form of fluid nourishment, it is eagerly swallowed. This desire for drinking is frequently more obvious in the case of young children. Nevertheless, there is often an indisposition manifested on the part of medical practitioners to order, and nurses to give, "drinks" whenever the patient asks for them, on the ground that the digestion may be disturbed. For this there is, perhaps, some excuse. In the case of typhoid fever, several trial experiments have been recently undertaken with the view of ascertaining if the excretion of urine is proportional to the amount of fluid ingested; in other words, if the kidneys retain their power of eliminating water in this disease. Dr. Edward F. Cushing, of Cleveland, Ohio, administered four ounces of pure water to a series of typhoid patients every fifteen minutes during the waking hours throughout the course of the fever. It was found that a large quantity of water could be borne without any discomfort by the patients, and also that an abundant flow of urine was secured. Just at first there was a little resentment displayed by a few, but these soon came to like the water. Other observers have conducted similar experiments, and all are agreed that patients are much more comfortable under the treatment, and that the nervous symptoms are greatly lessened. It would, therefore, seem as if we have here an additional means of combating the toxæmia of the disease, and the results certainly show that the eliminating capacity of the kidneys is little, if at all, impaired in enteric fever.

Certification of Deaths.

How long, one wonders, will it be before the present unsatisfactory and scandalous condition of the law and administration of this country with regard to death-certification is brought into line with the requirements of a civilised country? It is difficult to speak with patience of the confused practice that obtains at present. A medical man is bound under penalty to give a certificate of death to the relatives of a patient unless he can find a "reasonable excuse," and although the certificate is given without fee or reward, he may find the authorities at Somerset House wanting further information from him. On the other hand, any quack, pretender, or ignorant person may give a certificate which the local registrar—often a person of very little education—is willing to accept, and even no certificate at all may be given, and the body buried without the cause of death

being registered. At an inquest held at Southport the other day on the body of a woman, aged forty, it came out that she had been attended in her illness by a person calling himself a herbalist. This erudite individual had been treating the unfortunate subject of his ministrations with raspberry leaves, concoctions of slippery elm, and "reanimating drops." Whatever effect the first two of these remedies may have had, the "reanimating drops" were succeeded by a process of examination on the part of the patient, and as no medical man was called in, the herbalist gave a certificate saying that death was due to paralysis followed by epilepsy. Fortunately, the registrar had sufficient sense to refuse the certificate, and an inquest was ordered. The Coroner made some forcible remarks about the impropriety of the whole proceedings, saying that "a joiner, a bricklayer, or a collier might as well issue a certificate as a medical herbalist." The jury returned the verdict of "death from natural causes," and added the naive rider that the herbalist was "unwise" in issuing the certificate. It is difficult to see where the unwisdom came in; the man knew that the only way to avoid an inquest was to give a certificate, and that this was not unlikely to be accepted. The people who are "unwise" are those who allow their civic organisation to contain such a loophole for imposture and crime.

Sea Sickness or Altitude Sickness.

ALTHOUGH the success that attended the recent attempt of the bold aeronauts to travel in balloon from London to Paris cannot be said to bring that mode of locomotion within measurable distance of becoming an alternative to the usual route, it brings us face to face with its possibility. Whether, should it come to pass, travellers who at present endure the agonies of sea-sickness would gain thereby is another question. The emotions from which our parents suffered when first they ventured on a journey by train were as nothing to those that will await the pioneers in aerial navigation. The traditional "now we're off," after a parting kiss several times repeated, will be followed by a masterly swoop into the sky associated with a visceral constriction compared to which the flightiest lift, nay, even an ascension from the depths of a coal-mine, is but child's play. As far as one can judge, the accommodation available on the aerial vessel is not likely to allow of the distribution of travellers into social categories, so that a hideous promiscuity will be unavoidable. But sea sickness; shall we at last have exorcised this bogey by quitting the agitated surface of the waters for the more stable environment of the ambient air? The chances are that in evading sea sickness, which is one of "the ills we have," we shall be "flying to those we know not of." But, as a matter of fact, we do know something of "mountain sickness," and our information concerning it has been confirmed and added to by the published narratives of our soldiers in the recent expedition

to Thibet. Many of them suffered horribly from prostration with nausea and oppression when they reached the higher altitudes; indeed, their state was fully as bad as that of the sea-sick person who has reached the stage at which he "fears" that the ship may after all weather the storm. On the whole we are disposed to congratulate ourselves that air trips from London to Paris are unlikely to become fashionable within the near future; and if called upon to make our choice of the lesser of the two evils, we should prefer to take part in a motor-car accident to one the scene of which is laid in or near a balloon.

Modern Prescriptions.

THE present age is characterised, among other things, by the decay of the prescription. Some of the senior members of the profession regard this as a regrettable sign, whilst many of the younger ones snort "polypharmacy," take their pen, and write quickly "Jones' hypophosphites" or "Robinson's corpusculogen," without compunction or concealment. The art of prescription-writing in this country is certainly on the decline, but, on the other hand, the art of pharmacy is certainly rapidly improving, and it is quite open to debate whether the patient is not as well off with a well-found, carefully-blended preparation as with the quondam "blunderbuss" mixture. In the *Proceedings* of the Philadelphia County Medical Society for January of this year is a paper by Dr. M. C. Thrush, who took the trouble to inspect the prescription-files of two of the leading chemists in Philadelphia, running through five hundred consecutive prescriptions from each. In these prescriptions there were thirteen instances of chemical and pharmaceutical incompatibility, but only one of therapeutical incompatibility. Fifty prescriptions—all by old-fashioned physicians—contained six or more ingredients; seven hundred and eighteen, two to five ingredients; four hundred and eighty-four (less than half) contained official preparations only; three hundred and fifty-nine proprietary preparations, in whole or in part, and two, patent medicines. One of the latter, however, it is fair to state, was written by an osteopath. Dr. Thrush's conclusions were that the most able physicians employ the fewest drugs, and the best-educated prescribe only official preparations. The younger men generally showed marked want of knowledge in the art of prescribing, and it is sad to have to add that only 621 prescriptions were correctly written. These remarks of Dr. Thrush's are particularly interesting as showing the same tendencies in America as in this country. Our own conclusion would be that the medical curriculum is too full nowadays to allow of a full and accurate training in the art of prescribing.

PERSONAL.

THE KING, on the recommendation of the Home Secretary, has been pleased to appoint Dr. James Craufurd Dunlop, to be an additional member of the Royal Commission on the care and control of defective and feeble-minded persons.

THERE has been presented to the Dartmouth Cottage Hospital an excellent painting of the late Mr. Arthur Kyffin Crossfield, L.R.C.P., L.R.C.S. Edin., by the committee of that institution in memory of the valuable services which he rendered to the hospital as one of the honorary medical officers.

ON February 21st, in Convocation, the University of Oxford formally accepted the offer of Mr. Alfred Beit to found a professorship, lectureships, and a prize for an essay in Colonial history, and expressed their gratitude to Mr. Beit for his offer.

THE honorary Fellowship of the Royal College of Surgeons in Ireland was formally conferred on Anthony Traill, the Provost of Trinity College, on February 25th, when he signed the roll as an honorary Fellow of the College.

LIEUTENANT-COLONEL H. K. MCKAY, C.I.E. (Bengal) has been appointed Inspector-General of Civil Hospitals and Sanitary Commissioner Burmah, vice Lieutenant-Colonel S. Little. Major C. H. Bedford is posted to the Finance Department.

LIEUTENANT-COLONEL ALFRED F. S. CLARKE, R.A.M.C., on his leaving Sandhurst after twenty-two years' service as surgeon of the College, has been presented with a silver salver with suitable inscription and an opal and diamond ring for Mrs. Clarke, by the officers of the Royal Military College, past and present.

A PRESENTATION of a testimonial was made to Dr. W. W. Ireland at the Royal College of Physicians of Edinburgh last week, on the occasion of the fiftieth anniversary of his medical graduation.

DR. SYKES, medical officer of health for St. Pancras, has prepared a report on the subject of the large infantile mortality, and the Borough Council have requested him to elaborate a scheme.

A DISCUSSION upon the causes of the increased prevalence of anthrax in Great Britain will be opened by Professor Sheridan Delépine, at a meeting of the Incorporated Society of Medical Officers of Health to be held at 9, Adelphi Terrace, Strand, London, on March 10th, at 7.30 p.m. The chair will be taken by the president of the society, Dr. J. F. J. Sykes.

THE post of honorary surgeon to the Metropolitan Fire Brigade Widows' and Orphans' and General Benefit Fund rendered vacant by the death of Mr. Herbert Allingham has been accepted by Sir A. Fripp.

DR. W. M. HICKS, F.R.S., Principal of Sheffield University College, has been appointed one of the Vice-Presidents of the Mathematical and Physical Science section of the British Association; and Professor Arnold, also of University College, has been appointed a special lecturer.

FURTHER investigations, under the auspices of the Royal Society's Committee, into the causation of sleeping sickness in the Uganda Protectorate, will be undertaken by Professor E. A. Minchin, Jodrell Professor of Zoology in University College, London.

AMONG the list of those elected this year to the Royal Society are Dr. J. G. Adami, Professor of Pathology in McGill University, Montreal; Mr. E. W. MacBride Professor of Zoology in the same University; Dr. F. G. Hopkins, Reader in Chemical Physiology at Cambridge University, and Lieutenant-Colonel D. Prain, I.M.S.

M. ANDRE LEFEVRE has bequeathed £30,000 to the School of Anthropology, Paris, also his head.

PROFESSOR JOHN EDWARD SHORROCK MOORE, A.R.C.S., F.L.S., has been appointed Director of the Cancer Research, Professor Moore is at present acting

as Professor of Natural History in the London Royal College of Science and is well known as an investigator in cancer, having been associated in the work with Messrs. Farmer and Walker.

DR. W. J. BRUCE and Dr. H. R. Ellis have been appointed Medical Officers of the Colony of Lagos. Dr. Ellis has been attached to the Lagos Hospital and appointed for duty connected with the General Medical and Sanitary Work of Lagos Town. Dr. Bruce is at Ibadan with the Oshogbo Railway Service Medical Branch.

DR. MACNAUGHTON-JONES, Master of Obstetrics (*hon. causa.*) Royal University of Ireland, formerly University Professor of Midwifery in the Queen's University, has been elected Honorary Member of the Obstetrical Society of Leipzig.

To perpetuate the memory of the late Sir William Banks, M.D., L.R.C.P., of Liverpool, a subscription has been opened in that city, and so far has reached a total of £5,000.

MR. THOMAS HAYES has been elected to the office of clerk to St. Bartholomew's Hospital. Mr. Hayes has held the secretaryship of the East London Hospital for Children for many years.

MR. W. JOHNSON SMITH, F.R.C.S., principal medical officer of the Seamen's Hospital Society, Greenwich, after being a member of the surgical staff of that hospital for thirty-five years, is about to retire. In recognition of his public service, the medical staff of the Seamen's Hospital Society propose to entertain him at dinner, and present him with a testimonial, on Wednesday, April 5th, at the Trocadero Restaurant, Sir Patrick Manson will take the chair.

MR. CANNY RYALL, F.R.C.S.I., has been appointed Surgeon to the Queen's Jubilee Hospital, London.

H.R.H. THE DUCHESS OF ALBANY, President of the Ladies Association, accompanied by H.R.H. Princess Alexander of Teck, Princess d'Erbach, His Grace the Archbishop of Canterbury, and others, honoured the Royal Waterloo Hospital for Women and Children with a visit last week.

Special Correspondence.

[FROM OUR OWN CORRESPONDENTS.]

EDINBURGH.

ROYAL EDINBURGH ASYLUM: DR. CLOUSTON'S ANNUAL REPORT.—After giving the usual statistics for 1904 (a record year as to the total number of patients under treatment), Dr. Clouston alluded with satisfaction to the relief which the removal of 185 rate paid patients to Bangour Asylum had given to their wards, and to the increase in admissions of private patients rendered possible thereby. As the accommodation at Bangour consisted as yet only of large wards suitable cases had to be selected for sending there, and this had left a disproportionate number of weak, noisy, suicidal, epileptic, and paralysed patients in Morningside, so that scarcely any reduction of the nursing staff had been possible, and the expense of treatment had gone up. Twelve voluntary patients were received. The recovery rate among these was higher than among certified cases—65 per cent. last year and 50 per cent. over the past ten years. Having emphasized the need for prompt and early treatment of incipient mental disorder, Dr. Clouston observed that in the Scottish Acts there was concealed in the middle of a section for another purpose a vague provision for the treatment of any patient for six months with a view to cure if a doctor wrote a certificate to that effect. A very slight expansion and definition of this little-known and seldom acted on provision would enable public hospitals or local authorities to

set up psychiatric wards in a strictly legal manner. Mental disease should not be looked on as an isolated fact in the life history of mankind, but as one of a vast series of consequences of ignorantly or wilfully breaking the laws of healthful living. If a tenth of the thought and a twentieth of the effort at present expended on political discussion and unhealthy amusement were for a few generations given to health knowledge and disease prevention, men and women would soon recognise their health risks and duties. To see an Education Bill that made no provision for teaching health, an educational system that neglected the formation of self-control and character, was a vivid proof of the present fatuous state of mind in regard to this tremendous problem. Of the cause of insanity during the year, excessive drinking stood out first. As his previous statistics and conclusions had been much criticised, he had this year taken more than usual care to obtain correct histories, and had given the benefit of the doubt to all as to whom any doubt existed. In 19 per cent. of his cases alcoholism was the undoubted cause of the upset of the brain functions; this was 10 per cent. less than in 1903, probably correlated to the past year of dull trade. Alcoholic insanity, in the scientific sense, formed 15 per cent. of the admissions. His proportion of female alcoholics was steadily rising, and last year the total number actually exceeded that of the males. The admissions of general paralytics were down this year, but there was this peculiar feature that an unprecedented proportion—22 out of 49—occurred in women. This increase of general paralysis in modern times, especially among women of the uneducated classes, meant that the lives of some sections of urban populations were more immoral than formerly. The bodily condition of the patients admitted was very poor. Of the discharges last year 150 were recovered (32·8 per cent., or 9 below the average) and 177 relieved. The death-rate was higher than ever before—14·6 per cent. on the average, and 9 per cent. on the total number under treatment. The high death-rate was, in part, accounted for by the number of patients who died within a fortnight of admission, and the growing tendency among the poorer classes to send troublesome and senile "wrecks" to the asylum to die.

EDINBURGH ROYAL INFIRMARY AND HOSPITAL ADMINISTRATION.—Last week the managers had under consideration a communication from the British Medical Association inviting representatives to a conference in London bearing on hospital administration, with a view of remedying abuses. The resolutions which were to be discussed at this conference will probably appear in another column, and need not be repeated here. By a majority it was decided not to send a representative on the ground that certain of the resolutions to be considered—viz., that inability to pay for medical treatment be the consideration for admission, that no charge be made for treatment, that subscribers' letters shall cease, and that there be an age limit for the staff—were already in force in the infirmary, and that the others were outside the Charter. It seems to us that as a matter of courtesy, if for no other reason, the managers would have done well to have sent a representative to this conference, on the footing, of course, that their action in doing so bound them in no respect. In the action they took, however they were no doubt to a great extent justified by the peculiar position which the infirmary holds as a national, not merely a metropolitan charity, a position of which its pride is expressed in its motto, "Patet omnibus." And again, while it would be ridiculous to assert that its offices are never abused, it is doubtful whether any system of inquisition into the circumstances of those seeking advice (and practically this must form a fundamental part of any system for checking the undeserving applicant) would not do more harm by checking the attendance of the deserving poor than good by driving away the sturdy beggar; for the general opinion of medical men, both on the staff or outside of it, is that on the whole the institution is seldom used by those for whom it is not intended,

The medical representatives on the board were apparently divided as to the propriety of sending a delegate to London, as the mover of the motion which was carried and the mover and seconder of the amendment that the invitation be accepted were medical men.

GLASGOW.

HEALTH EXPERTS AND THE MEDICAL PROFESSION.—For several weeks a widely circulated religious paper called *The British Weekly* has had a page or part of a page of letterpress devoted to "England's Greatest Health Expert," who is no less a personage than Mr. Eustace Miles, M.A.—mark the degree—and to Mr. Eugen Sandow, late Music Hall Artiste, and generally billed as the "strong man," who has had an entire page to himself, with an illustration showing him addressing what is called a representative gathering of medical men. Parenthetically, we may say that this gentleman's portrait appears in one of the monthly magazines along with those of Harvey, Koch, Jenner, Pasteur, and Virchow, in an article with the heading "Great Healers of Mankind." The last week's issue of this enlightened publication, *The British Weekly* devotes considerable space in large type to "The last chance. Only twelve days more. The great *British Weekly* offer is now closing. Only a few days more will Mr. E. Miles be able to give the *British Weekly* readers the Miles Individual Health Course at the greatly reduced fee of £1 11s. 6d." Again, we are told that thousands of grateful patients throughout the country testify to Mr. Miles' success in their own individual cases. With reference to Mr. E. Sandow we read that "the greatest living specialist in dealing with nervous breakdown of the nervous system is Eugen Sandow. There is scarcely an ailment which has not yielded to his judicious treatment—chronic constipation, indigestion, loss of vigour, insomnia, and nerve troubles in general have all been cured permanently; while such scourges as asthma, incipient consumption, curvature of the spine, and general deformities have been fought and conquered." Let it be noted that Messrs. Miles and Sandow are referred to in this paper in a way that would indicate that the letterpress is not in the form of advertisement. If "Health Experts" can accomplish so much and prove themselves "Great Healers of Mankind" without passing through the usual portals of our Universities and colleges, for a five years' costly medical training, then why should we trouble sending our sons to such institutions to be carefully educated and trained in the various branches of preventive medicine, as well as giving the public the assurance of being skilled to treat disease in its numerous and complex forms by receiving degrees or qualifications to practise? We may just say that we are much surprised to find the names of several members of the medical profession appearing in connection with Mr. Sandow's flattering eulogies in the press. The subject has assumed such serious dimensions that we shall venture to refer to it again at no very distant date.

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

THE TREATMENT OF INOPERABLE CANCER.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have to thank you for your kind review, published in your last issue, of my pamphlet, "Some Methods of Hypodermic Medication in the Treatment of Inoperable Cancer," and in reference thereto I should be glad of your permission briefly to add some further conclusions which have recently suggested themselves to me.

I may remind the readers of my pamphlet that I therein raised the question between the possible connection between diabetes and cancer. This line of inquiry opened up the whole question of the glyco-genic function of the liver. The significance of this becomes at once apparent in view of (1) the excess of glycogen in foetal tissues, and (2) the known excess of glycogen in malignant growths. Bearing on these

points the factors which present themselves are these: Is there, in this reversion to glycogenic tissue and cell growth, (i) an over-production, or (ii) a non-conversion of glycogen, either locally or dependent generally on some nutritional disturbance of the liver or pancreas? Obviously in either case the point to be determined is the use of some means by which the excess of glycogen may be reduced. Many experiments subsequently undertaken with various ferments led to the discovery that the proteolytic ferment of the pancreas most effectually broke up glycogen, and led me to begin trial of hypodermic injections of trypsin.

Meanwhile, I have been gratified to learn that Dr. J. Beard, of Edinburgh, whose conclusions have been arrived at from embryological research, independently and amply confirms the view that the pancreas is at fault. He, while holding the view that the existence of an antithesis of enzymes is at the basis of cancer, and on the one hand an acid intracellular enzyme present; on the other, while alluding to the presence of traces of trypsin in normal tissues, significantly notes its absence in malignant tumours and the probable connection between this and their development. (a)

I am, Sir, yours truly,

JOHN A. SHAW-MACKENZIE.

42 Green Street, Park Lane, W.,
March 3rd, 1905.

THE LINCOLN TYPHOID EPIDEMIC.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The letter of "Viator," in your issue of March 1st, has a quality lacking in the vast majority of correspondents' letters, inasmuch as it offers solid comfort and advice instead of the familiar cold douche of criticism. It so happens that my attention was drawn some time ago to a French pamphlet describing the "Salvator," or Vaillard-Desmaroux, apparatus for sterilising water. So far as one could judge from that description, the apparatus seemed to be a model of ingenuity, simplicity and efficiency. Its practical value is evident from the fact that it has been widely adopted in France, especially by the military authorities. The Japanese, too, are at the present moment using the apparatus extensively for supplying their troops in Manchuria with pure water. In addition to the testimony of many distinguished French scientists, we have that of Dr. Thresh, the well-known English authority on water, who speaks highly of the merits of the Salvator.

The apparatus, however, has not yet become known generally to sanitary and engineering experts in this country, or the foregoing remarks would be superfluous. At the present moment the existence of a means of rapidly and effectively sterilising the water-supply of a town cannot be too widely known. "Viator" tells us that the apparatus could be brought over and set up within a week. The expense of such an installation would be comparatively small, and, in any case, a consideration of that kind should not be allowed for a moment to weigh in the balance against the chance of suffering and death imposed upon thousands of Lincolnians.

The question the country will want answered is, "What is Lincoln doing to cope with the present terrible disaster?" If it be subsequently shown that an apparatus exists capable of instantaneously converting a specifically polluted into a bacteriologically pure water supply, and if that safeguard be deliberately disregarded by the local authorities of Lincoln, one would not greatly care to occupy the position of any Councillor responsible for the maintenance of the present *non possumus* opportunism.

Science is science, and nowadays exact proof could be obtained within a few hours of the truth or other-

(a) "The Cancer Problem." By J. Beard, D.Sc., University Lecturer in Comparative Embryology, Edinburgh; *Lancet*, February 4th, 1905. "The Cancer Problem and Cancer Research." J. Beard, D.Sc., and John A. Shaw-Mackenzie, M.D., Lond.; *Lancet*, February 11th, 1905 (Correspondence).

wise of the claims of the Salvator apparatus to scientific confidence. Has Lincoln made that inquiry?

I am, Sir, yours truly,

DAVID WALSH, M.D.

Hanover Street, London, W.

THE VALUE OF LIGHT IN OUR DAILY LIFE. To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In reading the clear and simple summary of our knowledge of the value of light in our daily life, by Mr. Tucker, it is natural for a doctor to see with satisfaction that the Architect—*vide* the *Public Health Engineer*—is taking an interest in the subject, and that the scientific principles connected with it are likely to be studied by those engaged in the important work of architecture in its widest sense. There is no doubt that our Architects will have to study the questions of how best to heat and light our buildings, and that they must not remain in ignorance of the science which bears upon these important questions. How best to light and warm our houses are questions that require most serious attention, and at present they are questions that both chemists and architects find difficult to deal with, as they require special knowledge and study. Architects have not studied the questions of heating and lighting houses, and chemists generally consider these matters as belonging to architecture and not to chemistry. It is quite clear that a knowledge of how we ought to heat and light our houses is absolutely necessary to those who are engaged in architecture, and the subject is one which comes under the head of public health, in a very marked way.

I am, Sir, yours truly,

R. L.

THE LEGALITY OF BOGUS MEDICAL AND DENTAL COMPANIES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR

SIR,—I am compelled to take exception to a remark at the conclusion of your otherwise admirable article on the "Legality of Companies Formed for Medical and Dental Practice." You say "... whether the alleged cures are effected by electricity, magnetism, hypnosis, or humbug."

The association of electricity with humbug in your article is at least unfortunate, and on behalf of those who like myself, devote their whole time to electro-therapeutic work and believe in its possibilities, I must protest strongly against the implied suggestion.

The attitude of the Profession in the past has surely been hostile enough to the science of electro-therapeutics and those who practise it, without receiving encouragement from an important medical journal.

I am, Sir, yours truly,

RICHARD J. COWEN, L.R.C.P., L.R.C.S.
15 Half Moon Street, Mayfair, W.,

March 2nd, 1905.

[Our comments referred to practice by bogus companies, and had no reference to the use of electricity by properly qualified medical men. The position of electro-therapeutics in medicine is too clearly established to need defence, or to fear attack.—ED.]

International Association of the Medical Press.

THE conference of delegates of the International Medical Press Association will be held this year at Berne on April 27th and following days, under the presidency of Professor Cortezo, of Madrid.

Hygiene and Temperance.

A MEDICAL conference on the teaching of hygiene and temperance is to be held at the Examination Hall, Victoria Embankment, on Friday, March 24th, at 5 p.m., Sir William Broadbent presiding. Sir Victor Horsley is to speak on the present position of the scheme for education in hygiene and temperance; Sir Thomas Barlow on the present position of the medical profession in relation to alcohol; and Mr. W. McAdam Eccles, M.S., on the teaching in medical schools of the pharmacological and toxic properties of alcohol.

Special Articles.

SURGEON-GENERAL EVATT'S REPORT TO THE IRISH MEDICAL ASSOCIATION.

THE Council of the Irish Medical Association at its last meeting had again under consideration the unfortunate report on things in general which was presented to it by Surgeon-General Evatt, and to which we have had occasion to refer in terms of strong disapproval in our recent issues. The most important question, as we understand, which came before the Council was whether the report was to be circulated or not. To have accepted it would have meant not only the loss of the friendship and good wishes of the leaders of medicine in Ireland, and the sympathy and active assistance of the Irish Colleges, but would also have meant the resignation *in globo* of the Committee of Council. The meeting was, we regret to learn, a stormy one, but wise councils prevailed and the following resolution was adopted:—"That Surgeon-General Evatt's report be not published or circulated to members, and that the committee already appointed consider what portions of the report be adopted. We also, with no uncertain voice, disassociate from our programme all the offensive statements in the report which refer to the Royal Colleges of Surgeons and Physicians, and the members of the profession generally." We congratulate the Association on having passed successfully through a period of much difficulty, and on having successfully weathered the storms created by Surgeon-General Evatt's ferocious blasts. It was not to be expected that, during the passage, cross-currents could be entirely escaped, but they proved too insignificant to influence the course of the ship, and the rocks that would have torn the bottom out of the Association were escaped. The Irish Medical Association is a necessity to the welfare of the profession in Ireland, but it must be reorganised. It this is done in a thorough and permanent manner, we look forward to a future not such as that so vividly imagined by the learned and gallant general, but to one in which a representative body, harmoniously working will unify the medical profession and will raise it to the position which it should occupy in the councils of the land. We propose returning to this subject in our next issue.

Obituary.

JOSEPH HENRY HARRIS LAWRENCE, M.R.C.S. ENG.

THE news has come of the death of Mr. J. Harris Lawrence, for many years a practitioner in Widcombe where his father and brother were in practice before him. Mr. Lawrence left his native city last year, and few knew whither he had gone until news of his death under painful circumstances arrived from Australia. He was a well-known figure in Bath. Much sympathy will be felt for his widow and family who still reside in Bath.

RICHARD NOWELL HALLIWELL, M.R.C.S. ENG.

Mr. Halliwell, who, since his retirement seven or eight years ago, lived at Abbey Road, Llandudno, died last week at the age of 75, and is survived by two sons and a daughter.

CHARLES BROWNE, F.R.C.P. ED., M.R.C.S. ENG.

It is with great regret we record the sudden death of Dr. Charles Browne, at the age of 72, from heart failure, on February 21st. Charles Browne was specially known to, and valued by St. Thomas's and Guy's men; and in his earlier associations was a marked professional figure in South London. He was the son of Dr. Tobias Browne, a well known South London practitioner, and represented the third generation in the same practice; it was only in later years, when, wishing for more leisure, that he went to consulting rooms in Moorgate Street. For many years joint physician to the Equitable (London) Insurance Society,

he had had a lifelong connection with the Apothecaries' Society, of which his father was Master in 1865, and himself in 1901. Up to the time of his death he was still acting as the Society's visitor at the professional examinations held in their Hall. He was educated at Guy's, and took the L.S.A. in 1854, the M.R.C.S. Eng. 1855, and the F.R.C.P. Ed., in 1881.

PROFESSOR ADOLF BASTIAN.

PROFESSOR Adolf Bastian, director of the Berlin Ethnographical Museum, has died at Port of Spain, Trinidad, in his 79th year, while on a scientific expedition. He was for many years a distinguished traveller and had a wide reputation as the author of numerous ethnological and anthropological works, of which the best known is "The Peoples of Eastern Asia."

EDWARD ATKINSON, M.R.C.S. ENG., L.S.A.

MEDICAL and other professional men in Leeds must deeply regret the death of Mr. Edward Atkinson, surgeon, which took place on March 1st, at Harrogate. Mr. Atkinson became a member of the Royal College of Surgeons, England, in 1852, and after filling the post of house surgeon at King's College, he went out to the Crimea. He was attached to the hospital at Scutari, the scene of Florence Nightingale's devotion, afterwards travelling to Jerusalem to take up the position of surgeon at the English and Prussian Deaconesses' Hospital. He stayed there till 1860, and in his four years' work was associated with Dr. McGowan. On his return to England he settled in Leeds, but many years ago gave up private practice, and became solely a consulting surgeon. A short time since he gave up his consulting work, and went to reside at Harrogate. A love and knowledge of natural history had been fostered and increased by his residence in the East, and he was known as a clever speaker in the branches of science in which he was specially interested. He was a Fellow of the Linnean Society, and honorary curator in zoology at the Museum of the Leeds Philosophical and Literary Society. He had also filled the presidency of that body. In private life he was the most genial of men, and his company and friendship were greatly esteemed. Mr. Atkinson, who died at the age of 75, leaves a widow and several sons, the eldest of whom is Dr. F. E. Atkinson, medical officer of Health for Settle.

WILLIAM WHITE GEORGE, M.B., C.B. GLAS.

DR. William White George, son of the Rev. James George, of Dundee, died last week at Dunrossness, N.B. The deceased, who was only thirty years of age, received his early education at Dundee High School, and latterly at the University College. After taking his medical degree at Glasgow University, Dr. George was appointed medical officer of health to the Parish of Dunrossness, in Shetland, where he carried on an extensive private practice, extending over an area of about twenty miles. His genial temperament won for him great popularity. He had been married only eight months.

LADY LAKING.

LADY LAKING, wife of Sir Francis Laking, one of the King's Physicians in Ordinary, died last week at her residence, in Pall Mall, at the age of 62. Lady Laking was the daughter of Mr. Joseph Mansell, of Kensington, and was married to Sir Francis Laking in 1875. She leaves an only son, Mr. Guy Laking, keeper of the King's Armoury.

Laboratory Notes.

PLASMON OATS.

IN this preparation (International Plasmon Co., Ltd.) the best Scotch oats are treated in such a way that the husk and fibre are entirely removed and the oatmeal thus prepared is blended with Plasmon; a most valuable food is thus obtained—rich in nitrogenous principles and free from substances which might cause irritation. Our analysis has shown the following

results:—Water, 11.06 per cent.; ash, 2.15 per cent.; cold water extract, 9.30 per cent.; nitrogen, 3.25 per cent.; albuminoids, 20.60 per cent.

The water and ash are lower than in ordinary oatmeal, while the cold water extract and albuminoids are considerably increased, thus affording evidence of the nourishing and sustaining properties of this preparation. Plasmon oats only require four minutes boiling and when prepared resemble a fine oatmeal in taste.

ALLENBURY'S MILK FOOD COCOA.

(Prepared by Allen and Hanbury.)

WE found on analysis of this well-known Milk Food Cocoa that it contained a considerable proportion of the theobromine, the characteristic alkaloid of pure cocoa.

The mineral matter was 4.5 per cent., the fat from 17 to 18 per cent., and the cold water extract was as much as 64 per cent.; this latter figure agreeing well with a previous analysis. The proportion of matter soluble in cold water is important, as the easy digestibility of a cocoa depends much on its ready solubility. This stamps the preparation as one in every way desirable for invalids and persons of weak digestive powers.

Literature.

SURGERY OF THE VERMIFORM APPENDIX. (a)

THIS is a book which can be recommended to all classes of medical men, whether senior students, physicians, or surgeons. The subject is dealt with in a simple and methodical manner, rarities and obscure theories being absent or barely mentioned, so that the practical lesson which the authors essay to teach may not be obscured.

Much has been written upon diseases of the appendix, and there are still very divergent opinions held as to the part surgeons should play in their treatment. The present volume is a very concise *resumé* of the literature combined with the authors' well-known experience.

The subject of operation is dealt with fairly and dispassionately, but perhaps the directions when to operate might be stated in a more dogmatic manner. Dealing with the signs, symptoms, and pathology and indicating how cases should be individually judged is both honest and scientific, but in a short work of this character, which will be largely made use of by busy practitioners, dogmatism might save more lives than absolute accuracy. The subject treated of is one of absorbing interest, and the authors' method of treating it is pleasant and encourages thought.

INDEX-CATALOGUE OF THE U.S. LIBRARY. (b)

THE present volume of this great series of folios includes 8,706 author-titles, representing 2,599 volumes and 8,291 pamphlets, and 31,481 titles of articles in periodicals. In the first series the letter "L" terminated in the first third of the eighth volume; in this, the second series, it occupies the whole of the ninth volume, which includes the modern bibliography of labour, larynx, latrines, lens, leprosy, lichen, life-insurance, lips, lithotomy, liver, London, lungs, lupus, and so forth. Up to and including the present volume the series contains 267,231 author-titles, 239,518 book-titles, 238,444 pamphlet-titles, and 790,144 article-titles. The value of the series is known and appreciated by all students of medical literature who find their labour much lightened by reference to these ponderous volumes, which play the double part of facilitating the labours of the student and ensuring that the claims to originality that are based on ignorance of the past of medical literature will not have any

(a) "The Surgery of the Diseases of the Appendix Vermiformis and their Complications." By William Henry Battle, F.R.C.S., and Edred M. Corner, M.B., F.R.C.S. Pp. 208. Illustrations 11. Price 7s. 6d. net. London: Archibald Constable and Co. Ltd. 1904.

grounds for their existence. All who use the Index-Catalogue must feel grateful to the great Republic for its liberality in attempting and carrying out such a stupendous undertaking and so richly endowing medicine with such a valuable gift.

HOME NURSING AND HYGIENE. (a)

THIS handbook is the official publication of the St. Andrew's Ambulance Association. The subjects embraced by this small manual are somewhat extensive, but the authors have succeeded in condensing them within a very limited compass. No point of any importance in the nursing of the sick seems to have been omitted. There are altogether ten chapters, of which the first six are devoted to subjects connected with home nursing. The next three treat of hygiene, under the headings of "The House," "Food," and "Personal Health," while the last chapter deals with bandaging and surgical nursing generally. The volume as a whole forms a very suitable text-book, and one which will be of equal value to hospital nurses and to ambulance students. It will doubtless find many readers outside the class for whom it has been more especially prepared.

Medical News.

French Congress of Climatotherapy and Hygiene.

IT has been decided to hold the second Congress of the Association of French Physicians, especially interested in Climatotherapy at Arcachon, from April 24th to 29th. The district is one of the most beautiful on the Continent, and a most successful meeting is anticipated. Dr. Renant, Professor of the Faculty of Medicine of Lyons has been elected President and Dr. Festal of Arcachon, General Secretary, to whom all communications from members of the profession in Great Britain desirous of being present should be addressed. A welcome is assured to English medical men.

Cairo School of Medicine.

AT the dinner given recently at the School of Medicine, Cairo, Dr. Wm. St. Clair Symmers, who is leaving the service of the Egyptian Government to take up his appointment of Professor of Pathology at Belfast, was the guest of the evening.

Among those present were Dr. H. P. Keatinge, Director of the Cairo Medical School, Dr. Ibrahim Hassan Pasha, Dr. G. Elliott-Smith, Dr. W. H. Wilson, Dr. J. R. Naylor, Dr. A. Looss, Dr. W. A. Schmidt, Mr. F. R. Milton, Dr. P. C. Tribe, Dr. E. C. Fischer, Prof. L. P. Phillips, Prof. F. C. Madden, Dr. Harold Nolan, Dr. Shukry Bey, Dr. Innes Bey, Dr. Arloing, Dr. F. M. Sandwith, Mr. Reginald Harrison, and Dr. Charles Todd. Dr. Ibrahim Hassan Pasha gave the toast "Prosperity to the School of Medicine," and Dr. Keatinge proposed the health of Dr. Symmers. The toast was drunk with musical honours, after which Dr. Keatinge presented Dr. Symmers with a silver bowl, subscribed for by past and present professors of the Cairo Medical School. Dr. Keatinge then proposed the health of the visitors, coupled with the names of Dr. Arloing (Lyons University) who is studying cattle plague at Cairo, and Mr. Reginald Harrison (London). Dr. Arloing, who spoke in French, and Mr. Harrison responded, and the proceedings terminated.

St. Thomas's Hospital.

THE following gentlemen have been selected as house officers from Tuesday, March 7th, 1905:—

Resident House Physicians.—R. E. Whitting, M.A., M.B., B.C.Cantab., F. A. Brodribb, M.R.C.S., L.R.C.P., A. G. Gibson, B.A., M.B., B.Ch.Oxon., B.Sc.Lond. (extension), K. Takaki, M.R.C.S., L.R.C.P. (extension).

House Physicians to Out-Patients.—H. R. Dean, B.A., M.B., B.Ch.Oxon., M.R.C.S., L.R.C.P., A. C. Inman, M.A., M.B., B.Ch.Oxon.

(a) "Home Nursing and Hygiene." By J. Wallace Anderson, M.D., F.F.P.S.G., and George H. Edington, M.D., F.F.P.S.G. Illustrated, 1s. net. Glasgow: St. Andrew's Ambulance Association. 1904.

Resident House Surgeons.—H. A. Kisch, M.R.C.S., L.R.C.P., G. R. Footner, B.A.Cantab., M.R.C.S., L.R.C.P., R. E. G. Gray, M.A.Cantab., M.R.C.S., L.R.C.P., J. C. F. D. Vaughan, M.R.C.S., L.R.C.P.

House Surgeons to Out-Patients.—L. E. C. Norbury, M.R.C.S., L.R.C.P., D. K. Cutts, M.R.C.S., L.R.C.P., J. H. Bletsoe, M.B., B.S.Lond., M.R.C.S., L.R.C.P., R. J. C. Thompson, M.R.C.S., L.R.C.P.

Obstetric House Physicians.—(Senior) A. W. Parry, M.R.C.S., L.R.C.P., (Junior) N. C. Carver, B.A., B.C.Cantab., M.R.C.S., L.R.C.P.

Ophthalmic House Surgeons.—(Senior) A. B. Bradford, M.B., B.S.Durh., M.R.C.S., L.R.C.P., (Junior) F. R. E. Wright, M.B.Lond., M.R.C.S., L.R.C.P., D.P.H.

Special Departments:—*Throat*, W. G. Howarth, B.A.Cantab., M.R.C.S., L.R.C.P., G. J. Langley, M.B., B.S.Lond.; *Skin*, W. Haward, M.B., B.S.Durh., M.R.C.S., L.R.C.P., N. Carpmal, F.R.C.S., L.R.C.P.; *Ear*, J. H. Drew, M.R.C.S., L.R.C.P., C. Ll. Morgan, M.R.C.S., L.R.C.P.

Electrical Department.—F. Fowler, M.R.C.S., L.R.C.P. L.S.A.,

X-Ray Department.—H. M. Thomas, M.R.C.S., L.R.C.P.

Medical Sickness and Accident Society.

THE usual monthly meeting of the Executive Committee of the Medical Sickness, Annuity and Life Assurance Society was held at 429, Strand, London, W.C., on 24th ult.

There were present Dr. de Havilland Hall (in the chair), Dr. M. Greenwood, Mr. H. P. Symonds (Oxford), Dr. J. Bindrey James, Mr. F. S. Edwards, Mr. Edward Bartlett, Mr. William Thomas (Birmingham), Dr. Frederick S. Palmer, Dr. F. J. Allan, Dr. W. Knowsley, Sibley, and Dr. T. B. Ball.

The Committee examined a long list of sickness claims, the majority of which have been received from members of the Society in country practices, who are necessarily much exposed to bad weather in the early season of the year. The claims, though numerous, are mostly of short duration.

The Committee resolved to pay a cash bonus to those members of the Society whose certificates had been less than three years in force on December 31st, 1898, and who accordingly did not participate in the allotment of surplus then made. It is hoped that these bonuses will be paid before the annual general meeting, to be held in May next. Prospectuses and all particulars of Mr. F. Addismitth, Secretary Medical Sickness and Accident Society, 33, Chancery Lane, London, W.C.

Royal College of Surgeons, Ireland.

Fellowship Examination.—Miss A. F. M. Cornell, L.R.C.S.Edin., &c., having passed the necessary examination, has been admitted a Fellow of the College. The following candidates passed the primary part of the Fellowship Examination:—Mr. J. Campbell, L.R.C.S.I. &c.; Mr. H. B. H. Cunningham, M.R.C.S., Eng., &c.; Mr. D. Adams, Mr. R. M. Bronte, Mr. J. D'Alton, Mr. P. G. T. Elvery, Mr. J. B. Hanafin, Mr. F. M. Hewson, Mr. J. Molyneux, Mr. C. Sheahan, Mr. T. Sheeby, and Mr. G. F. Shepherd.

Diploma in Public Health.—The following candidates passed the Conjoint Examination for the Diploma in Public Health:—Mr. E. A. Bourke, L.R.C.S.I., &c.; Mr. P. T. Bolger, F.R.C.S.I.; and Mr. S. G. Gordon, L.R.C.S.I., &c.

Licence in Dental Surgery.—Mr. T. Flanagan having passed the necessary examination was admitted a Licentiate in Dental Surgery. Mr. A. E. Weinstock passed the primary part of the Dental Examination.

THE medical study tour in Germany this year will start from Munich on September 13th. The tour will comprise visits to the following watering places: Ischl, Reichenhall, Berchtesgaden, Gastein, Gossensass, Levico, Roncegno, Riva, Gardone, Solo, Arco, and Meran, where the tourists will arrive in time for the meeting of the German Association of Scientists and Physicians.

Notices to Correspondents, Short Letters, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive Signature or Initial*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in re-forwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

BOTANIST.—Hundreds of tons of weeds are exported yearly from Europe to the United States. Last year ten tons of poison hemlock, fifteen tons of tansy, and sixty tons of horehound were sent. Burdock is largely used there for its supposed virtues in diseases of the blood-system.

DR. M. (Hatfield).—Your question as to sugar as a food is very a propos just now. Sir William Gull recommends dried raisins and chocolate, which, he says, furnish a supply of sugar during any unusual expenditure of energy. Most athletes are aware of this. It is said the health of our army in S.A. was helped in no small degree by the supply of sugar in jam.

TURNING THE TABLES.

THE Daily News, usually a mine of universal information, had the following note last week:—"Dr. William Osler," says a New York telegram, "admits that he was only joking when he suggested that sexagenarians should be chloroformed." The world breathes again! The news reminds us to be thankful for the existence of the Atlantic cable service. But for ocean telegraphy, we might have lingered for days under the awful delusion that Dr. William Osler was serious. And, by the way—who is Dr. William Osler? Anybody know? The *Daily News* has clearly been hoaxed by Professor Osler, and seeks to turn the tables by affecting ignorance of his personality.

MEDICINE AND COMMERCE.—Members of the profession desirous of an appointment as Medical Attendant to a commercial house of standing, will find one advertised in our to-day's issue by Messrs. Cadbury Brothers, who employ 4,000 workpeople. We understand the salary attached to the post is considerable.

DR. MENESTRIER (Paris).—Your paper was duly received, and is marked for early insertion.

DR. A. D. F.—The communication in its present form is too long for our space. If you can reduce it to one-half, we will return it for your perusal.

D. P. H. (Leeds).—Dr. Hamer, Assist. M.O.H. of the L.C.C., gave as his opinion, after twelve years of serving, that the East End Aliens were most ready to conform to sanitary requirements.

DR. R.—Beer drinkers are probably more liable to multiple peripheral neuritis than spirit drinkers. It is a common affection in Lancashire among alcoholics, and in the past has perhaps been often due to arsenical impurities as first shown in the Manchester epidemic.

SPRONG.—A mineral water used in its potable sense must be regarded as a food product. Some waters contain traces of iron, lithium, sodium carbonate, and chloride, and have therefore a medicinal value.

OUT-patients frequently try the doctor's patience by long wiled explanations of symptoms real and imaginary, but recently a small boy came to be treated bearing a grubby note which briefly stated, "Bill as beliake."

Meetings of the Societies, Lectures, &c.

WEDNESDAY, MARCH 8th.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY (20 Hanover Square, W.).—8.30 p.m. Discussion on the Ethics of Health Resort Treatment (opened by Dr. L. Williams).

DERMATOLOGICAL SOCIETY OF LONDON (11 Chandos Street, Cavendish Square, W.).—5.15 p.m. Demonstration of Cases of Interest.

HUNTERIAN SOCIETY (London Institution, Finsbury Circus, E.C.).—8.30 p.m. Pathological Evening. Exhibition of Specimens.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m. Mr. J. Cantlie: Clinique. (Surgical.) 5.15 p.m. Dr. F. J. McCann: The Treatment of Puerperal Septicæ.

CENTRAL LONDON TROAT AND EAR HOSPITAL (Gray's Inn Road, W.C.).—5 p.m. Demonstration:—Mr. Nourse: Nasal and Aural Accessory Sinuses.

THURSDAY, MARCH 9th.

BRITISH GYNÆCOLOGICAL SOCIETY (20 Hanover Square, W.).—8 p.m. Specimens will be shown by Dr. F. Edge. Paper:—Dr. I. Parsons: The Choice of Treatment for Fibromyoma of the Uterus.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM, 11, Chandos St., Cavendish Square, W.—8 p.m. Clinical Meeting. Cases will be shown by Mr. E. Chatterton, Mr. C. Blair, Mr. A. Ogilvy, Mr. J. H. Parsons and Mr. A. Lawson, Mr. J. H. Parsons, Mr. R. E. Bickerton, Mr. H. McMullen.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m. Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m. Mr. A. H. Tubby. Orthopedic Surgery.

FRIDAY, MARCH 10th.

THE INCORPORATED SOCIETY OF MEDICAL OFFICERS OF HEALTH (9, Adelphi Terrace, Strand, W.C.).—7.30 p.m. Discussion of the Causes of the Increased Prevalence of Anthrax in Great Britain (opened by a paper read by Prof. S. Delepine).

CLINICAL SOCIETY OF LONDON (20 Hanover Square, W.).—8.15 p.m.—Mr. J. Berry will exhibit a Case, showing the Result of a Rhinoplasty Operation: a paper will be read at a subsequent meeting. 8.30 p.m. Papers:—Dr. W. H. White: A Case of Acute Rheumatoid Arthritis (with epididymo-epididymitis demonstration).—Dr. E. Abrahams: Arthritis Deformans and its Allies.—Mr. D. Drew: Three Cases of Stenosis of the Ureter.

BRITISH RHINOLOGICAL, LARYNGOLOGICAL, AND OTOLOGICAL ASSOCIATION (Medical Society's Rooms, 11 Chandos Street, Cavendish Square, W.).—4 p.m. Cases will be shown by Mr. C. Nourse, Dr. P. H. Abercrombie, Dr. Kelson, Dr. W. Wingrave, Dr. Lodge, Mr. H. Barwell, and Dr. A. Wylie. Discussion on Dr. J. S. Wallace's paper on Nasal Obstruction and Mouth Breathing.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m. Mr. H. W. Dodd: Clinique. (Eye.)

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—4.30 p.m. Lecture:—Dr. E. M. Leslie: Prognosis in Acute Pulmonary Affections.

TUESDAY, MARCH 14th.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—4.30 p.m. Dr. E. M. Leslie: Prognosis in Chronic Pulmonary Affections.

Vacancies.

Navy Medical Department.—Three Dental Surgeons for Portsmouth, Plymouth and Chatham. Salary £1 per diem and travelling expenses when necessary. Applications to the Director General, Medical Department of the Navy, 18 Victoria Street, S.W. (See Advt.)

Birkenhead Union.—Resident Assistant Medical Officer. Salary £120 per annum, with board, washing, and apartments. Applications to John Carter, Clerk to the Guardians, Poor-law Offices, Birkenhead.

Lincoln County Hospital.—Senior Male House Surgeon. Salary £100 per annum with board, lodging, and washing. Applications to the Secretary, 2 Bank Street, Lincoln.

Paddington Green Children's Hospital, London, W.—Matron. Salary £100 per annum, including washing allowance. Applications to the Secretary, Paddington Green Children's Hospital, London, W.

Herts County Asylum, Hill End, St. Albans.—Junior Assistant Medical Officer. Salary £150 a year, with board, lodging, and washing. Applications to the Medical Superintendent.

Leeds General Infirmary.—Resident Casualty Officer. Salary £100 a year, with board, lodging, and washing. Applications to Thomas Blair, General Manager.

Bradford Children's Hospital.—House Surgeon. Salary £100 per annum. Applications to C. V. Woodcock, Secretary.

North Cambridgeshire Hospital, Wisbech.—Male Resident Medical Officer. Salary £100 per annum, with furnished rooms, attendance, coals, gas, and washing. Applications to William F. Bray, Secretary, Wisbech.

Royal Dental Hospital of London.—School of Dental Surgery, Leicester Square, W.C.—Demonstrator of Practical Dental Surgery. Salary £100 per annum. Applications to the Dean.

Hydropathic Establishment.—Resident Medical Officer. Salary £200 per annum, with free quarters for medical officer and his wife. Applications to the Schoolastic, Clerical, and Medical Assn., Ltd., 22 Craven Street, Trafalgar Square, W.C.

Messrs. Cadbury Bros.—Factory Medical Attendant for their 4,000 workpeople. Preference given to a total abstainer. For Particulars address "B.C." at Bournville. (See Advt.)

Appointments.

ALDOUS, G. F., F.R.C.S. Edin., Assistant Surgeon to the East Cornwall Hospital, Plymouth.

BRADLEY, J., Certifying Surgeon under the Factory and Workshop Act for the Gortin District of the county of Tyrone.

FOX, E. L., M.D. Cantab., Physician to the East Cornwall Hospital, Plymouth.

GRÜNER, O. C., M.B. Lond., Honorary Pathologist to the Leeds Public Dispensary.

KILICK, C. R., M.B. Lond., L.S.A., Certifying Surgeon under the Factory and Workshop Act for the Williton Districts of the county of Somerset.

LUCY, R. H., K.B., C.M. Edin., Surgeon to the East Cornwall Hospital, Plymouth.

MORRICE, George Gavin, M.A., M.D. Cantab., M.R.C.P., Physician to the Dorset County Hospital.

Births.

BOUSFIELD.—On March 2nd, at 35 Princes Square, W., the wife of Stanley Bousfield, M.A., M.B., of a son.

Marriages.

STEEN—BARNES.—On March 1st, at St. Mary's Church, Twickenham, Robert Hunter Steen, M.D. Lond., Medical Superintendent of the City of London Asylum, Stone, to Alice, daughter of the late Lawrence Barnes, of Ealing.

Deaths.

GORDON GREEN.—On March 2nd, at 85 Waverley Road, Southsea, George Gordon, the infant son of Staff-Surgeon Henry William and Maud Gordon Green, aged six weeks.

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

Original Communications.

REMARKS ON LOCALISED FLUSHING AND SWEATING OF THE CHEEK ON EATING, ALSO ON "STRIÆ PATELLARES."

By F. PARKES WEBER, M.D., F.R.C.P.,
Physician to the German Hospital, London, and to the
Mount Vernon Hospital for Consumption, Hampstead.

THE patient in question is now aged 26½ years. (a) When he eats anything solid (for instance, a piece of sugar or an apple) a patch of redness appears almost immediately on the left side of the face as if he had received a sharp blow on the cheek. The reddened area is very hot, and sweating quickly follows. Occasionally a much smaller area of redness and sweating appears on the right side of the face, in front of the lobe of the ear, when the phenomena on the left side are at their maximum. The swallowing of fluids, such as milk, &c., does not cause the flushing and sweating to appear, but the rolling of a little vinegar and water about in the mouth (without biting or swallowing) calls forth the curious reaction fairly promptly. The reaction commences more quickly when he uses his teeth on the right side for biting his food than when he uses those on the left side. By merely opening and shutting his jaws or chewing a piece of wood (by pretending to eat) a very slight degree of redness is all that can be produced. The flushing and sweating subsides two or three minutes after he leaves off eating, but it takes a longer time for the redness to completely disappear. It was found that the phenomena were somewhat less marked when a cocaine lozenge was taken before his food, but the use of these cocaine lozenges has not been encouraged. A similar diminution in the symptoms followed treatment by bromide and belladonna (10 minims of the tincture three times daily) internally, and belladonna liniment externally. The effect of belladonna in checking unilateral and local sweating has been specially noted by Ringer. After much mental worry a middle-aged man suffered from excessive sweating of both cheeks, coming on while eating (especially hot meat or vinegar), but ceasing immediately after the meal. This sweating was completely stopped by ten drops of tincture of belladonna three times

daily. (Ringer and Sainsbury's "Therapeutics," thirteenth edition, 1897, p. 527.)

A case somewhat similar to the present was recorded by W. H. Haynes (*New York Med. Journ.*, December 25th, 1897) in a girl, æt. 19, of neuropathic ancestry. Any sweet or sour substance, when placed in her mouth, caused immediately, together with the flow of saliva, the whole of the right side (which was larger than the left side) of her face to become scarlet and noticeably enlarged, the phenomena subsiding very soon after removal of the determining cause in the mouth. In the present case there is no neuropathic family history. The patient suffered from appendicitis in December, 1894, and the appendicitis was followed by parotid buboes on both sides of the face, which had to be opened, and the scars of which still remain. About March, 1895, he was operated on for the appendicitis, and it was after that operation that the flushing and sweating of the face were first noticed. I believe the most probable explanation of the phenomenon to be that some sympathetic nerve fibres are involved in scar tissue (on both sides, but chiefly on the left side) and are stretched or pulled on owing to the physiological swelling of the salivary glands during eating. There is very slight diminution of tactile sensation in the neighbourhood of the scars. Suppuration of the parotid has been known to have been followed by sweating of the face. Mr. R. J. Godlee has kindly given me an instance of this sequence of events in the case of a middle-aged woman. In 1901, whenever she ate any solid or sharp-tasting food a red flush appeared almost immediately, which was very annoying. The history was that a parotid bubo on each side of the face followed an abdominal operation in 1890; these had to be opened and got well. But in 1901 there was recurrence of the swelling, together with ear disease; this was followed by the peculiar flushing on one side. In the present case no localised sweating or flushing occurs when the patient becomes hot by exercise or excitement, and there are no pupillary or other phenomena indicating any involvement of the rest of the cervical sympathetic. The patient's general health is now good. The appendicitis scar is healthy, and there is no sign of present disease of the thoracic and abdominal viscera or of the central nervous system. The diminution of hearing on the left side is due to old middle-ear disease. The knee-jerks are natural.

The rather uncommon atrophic transverse scars in front of this patient's knee-caps, and just above them, known as *striae patellares*, are

(a) The case was shown by Dr. Weber at a Clinical Evening of the Clinical Society on October 22nd, 1897, and again on January 27th, 1905.

peculiarly well marked and long. Like lineæ gravidarum and the lineæ due to obvious distension of the skin by ascites, œdema, obesity and local tumours of any kind, striæ patellares and other so-called "idiopathic" striæ sometimes met with about the shoulders, elbows and thighs of young growing persons doubtless originate from gradual rupture of the deeper layers of the cutis. Striæ patellares sometimes occur below as well as in front of and above the patellæ; sometimes they are better marked on the outer side of the joint, and they are not always symmetrical in the two limbs. In the present case they were first noticed after the attack of appendicitis ten years ago, and therefore were probably a result of the patient lying in bed with his knees flexed, the skin in front of the knees being thus tightly stretched at a time when he was growing rapidly and when his general nutrition was greatly affected by the appendicitis. Striæ patellares have been more frequently noticed after typhoid fever than after other febrile diseases, such as scarlet fever, pneumonia, appendicitis and colitis. My colleague, Dr. Zum Busch, kindly showed me an excellent example of striæ patellares in a young man at the German Hospital, in whom they probably arose when he suffered from osteo-myelitis about ten years previously.

Similar striæ after febrile diseases sometimes occur in other positions, as the arms, loins and outer surfaces of the thighs. Sir Dyce Duckworth (*Brit. Journal of Dermatology*, 1893, vol. v, p. 357) recorded striæ across the outer part of the left thigh after typhoid fever in a boy, æt. 15. There were similar parallel stripes on the outer side of each leg above the malleolus. In that case the excessive hyperæsthesia of the skin in the distribution of the external and middle cutaneous nerves suggests the presence likewise of the condition now generally known as "meralgia paræsthetica" (W. K. Roth, 1895), or "Bernhardt's paræsthesia" of the thigh (*Neurologisches Centralblatt*, 1895, p. 242), of which three years ago I met with a typical example following suppuration connected with vaccination (*Brain*, Summer, 1902, p. 353). The meralgia paræsthetica in my case gradually disappeared completely in the course of eight or nine months.

Excellent papers on the nature and cause of "striæ patellares" have recently been published by G. Fischer (*Münchener med. Woch.*, 1904, No. 11, p. 482), H. Köbner (*ibid.*, 1904, No. 21, p. 928), and J. L. Bunch (*British Journal of Dermatology*, January, 1905, p. 1). Actual microscopic examination of the striæ shows that they are due to rupture or "cleavage" of the deeper layers of the cutis, but much remains to be worked out in regard to their etiology, and especially their relation to stretching of the skin, growth of long bones and typhoid fever. I would only point out that at the height of the fever in cases of typhoid fever there may be a peculiar nutritional condition of the skin present. It is well known that chronic psoriasis sometimes more or less completely disappears during typhoid fever, to generally reappear sooner or later after recovery from the fever. Small wounds made during the height of the fever (as in opening small abscesses) have a tendency to gape in a most peculiar manner before they ultimately heal up by granulation. Some time since, in a grave typhoid fever case, a boil on the

front of the thigh was incised, and I observed that in the course of the next day the skin retracted so much that the small incision came to appear like a big fissure in the skin, the wound afterwards healing by granulation. Possibly in some cases the tendency to skin cleavage during typhoid fever may be partly due to the presence of excessive diarrhœa, which increases the ordinary febrile dryness of the tissues. It is not right to infer that because active growth of long bones, continued flexion of joints, and typhoid and other febrile diseases are not usually followed by "striæ patellares" or by similar striæ in other positions, therefore the striæ arise altogether independently of such supposed causes. By a similar line of argument one would arrive at once at the conclusion that tabes dorsalis and general paralysis of the insane had no connection with syphilis.

There are certainly very few cases of these cutaneous striæ remaining in which none of the causes referred to (not even active growth of long bones) can be ascertained, and which can really be classed as "idiopathic." Doubtless, however, a personal disposition plays a great part in the development of those striæ which are not obviously due to stretching. In 1897 I saw a well-developed muscular clerk, æt. 17, who had typical striæ over his shoulders, somewhat in the direction of the fibres of the deltoid muscle. Owing to their freshness they had a bluish, not a white appearance, and could therefore not as yet be literally termed striæ albicantes. There had been no illness, accumulation of fat, or œdema to account for the skin cleavage in that case, but the boy was growing rapidly.

A NEW FORM OF UTERINE DILATOR.

By ALEXANDER DUKE, F.R.C.P.

FOR those numerous gynæcologists who still prefer the Hegar dilator to the various other forms of divaricating make, the instrument depicted will, I venture to say, be found in practice an improvement.

It consists of a central metal rod, perforated from end to end (this offering much less resistance in introduction than the solid form, and also permitting of the escape of any existing secretions). *This need not be withdrawn after introduction till full dilation is effected.*

The four sides of central rod, from inch of point, are grooved, allowing the easy introduction of the four side pieces (seen in illustration) *one at a time*, according to the additional expansion required.

When these have been slid along the grooves full length, the amount of dilatation gained should equal a much larger number of Hegar's solid rods, introduced consecutively. This unilateral expansion carried on at short intervals by the introduction of the sliding side pieces I consider an advantage, and will, I think, ensure the dilatation required, with the expenditure of less time, less pain to the patient (if not anæsthetised), and less force on the part of operator.

The perforation in centre rod can also be used through which to inject some lubricating oil or glycerine (during or after introduction), and which, by gravitating outwards, should facilitate the sliding action of the side pieces

in addition. Any sized dilator can be made on this plan, and I should imagine a large size might be found useful in cases of eclampsia, where rapid delivery was imperative, in place of

the formidable instruments with screw, which are more than likely, even in skilled hands, to produce lacerations. The application of a 10 per cent. solution of eucaine or cocaine for ten minutes previously to cervix should facilitate introduction by the relaxation produced, and also mitigate pain in those cases where general anæsthesia is not considered advisable.

Firm pressure from above, over uterus by left hand will, I think, be found to facilitate the introduction of dilator better than traction on cervix by volsella or tenaculum. The instrument has been neatly made for me by Messrs. Hewlett and Son, Charlotte Street, E.C.

FŒTID BRONCHITIS.

By DR. BARBIER,
Of the Faculty of Medicine of Paris.

FŒTID bronchitis is characterised by a group of symptoms which may be classified as follows:—In most instances the patient has for years been suffering from dilated bronchi. The general health may be fairly good and the local lesions may have been stationary for years, when, all at once, disquieting manifestations supervene. The temperature suddenly rises to 102° F. or 104° F., with shivering and sharp intra-thoracic pain. There is obstinate cough, occurring in paroxysms of some duration, and, lastly, the expectoration is fœtid. Sometimes this fœtor makes its appearance quite suddenly, and one is surprised to find that the sputum, which was previously merely musty without anything characteristic, all at once becomes horribly fœtid. At other times, on the contrary, the fœtor of the sputum is preceded by gradually-increasing fœtor of the breath. The latter is usually not very marked, and must be sought for, but it is soon followed by fœtor of the sputum. When this occurs the character of the sputum changes; it becomes more liquid and of a greyish colour, and it separates in the spittoon into several layers, assuming, in fact, appearances somewhat similar to those of pulmonary gangrene. The fœtid bronchorrhœa lasts for a variable period, then ultimately disappears, or else causes death by hectic fever, and, more particularly, by gangrene of the lung.

These are the general features of the disease, but it

will be well to study each symptom somewhat more in detail. I have stated that fœtid bronchitis most commonly occurs in the subjects of dilated bronchi, and is ushered in by an aggravation of the constitutional condition, along with special manifestations, the most important being fœtor of the sputum. Fœtor of the breath and expectoration usually makes its appearance in the course of old-standing bronchiectasis, whence the name fœtid bronchorrhœa, or fœtid bronchiectasis, is sometimes given to this variety of putrid bronchitis. It is the most characteristic feature of the fully-developed disease. Eichhorst gives us an excellent description of the sputum. It is profuse, and the liquid is greenish-brown, clayey, or blood-streaked. After a time it separates into a lower sedimentous layer, a thin sero-liquid middle layer, and an upper frothy layer containing muco-purulent masses. In the lowest layer we find the peculiar formations described by Dittrich under the name of myotic bronchial plugs. These vary in size from a pin's head to a large pea. They are white or grey or brown, the more recent they are the lighter being the tint. They have the consistence of porridge, and when squeezed flat they give off a foul odour. Histologically these plugs are formed of granular debris itself, made up of filaments and spores. Leyden and Jaffé gave the name *Leptothrix pulmonalis* to these spores, and they mention that when treated with tincture of iodine they take on a brownish-yellow or violet-blue colour. Dittrich's plugs also contain pus corpuscles, especially when recent, spirillæ, the remains of red corpuscles and fatty acids, the closely-packed needles whereof form a lace-work which might very well be mistaken for elastic tissue.

Chemical analysis of these plugs led Jaffé to conclude that they are formed of fatty acids, leucine, tyrosine, sulphuretted hydrogen and ammonia. Filchner and Saltnikoff have isolated from the putrid expectoration a ferment having the same action as trypsin.

These are indeed the principal characters of the expectoration in fœtid bronchitis, but we may complete the description by a few additions. For instance, authors insist on the copiousness of the expectoration, but this need not excite surprise considering that the disease occurs in the course of a fœtid bronchorrhœa. In fœtid bronchitis, says Dr. Barié, the catarrhal secretion is very abundant, especially when there is a tendency to bronchiectasis. Even the appearance of the sputum varies. Sometimes it answers closely to the description given by Eichhorst, sometimes it is more liquid, and of a greyish colour (Classic). However this may be, placed apart in a receptacle, the expectoration invariably separates into several layers, of which the lowest contains the plugs described by Dittrich. The fœtor of the expectoration is the most characteristic feature, but this varies within wide limits. In some cases it is as marked as in typical pulmonary gangrene, but as a rule it is merely disagreeable, more or less fœtid, but *à la rigueur* supportable, not the fœtor described so vividly by Trouseau as one that "nauseates a whole wardful of patients." The odour is less suggestive of decomposition than of mere mustiness; it may be sour or sweet, or resemble that of sulphuretted hydrogen, while in mild cases the fœtor may only amount to acidity. This symptom, however, may be wanting for long periods of time; indeed, a feature to which special attention has been called by a number of observers is the intermittent character of the fœtor. It appears and disappears at irregular intervals, without apparent cause, and in spite of every kind of treatment. This very intermittence is of great assistance in arriving at a differential diagnosis between putrid bronchitis and true pulmonary gangrene. Long before the sputum becomes distinctly fœtid patients often complain of foul breath, a disagreeable odour of decayed teeth or rotting fish. The fœtor increases as soon as the patient begins to talk or cough, when gusts of foul odour escape from the mouth and pollute the air for a considerable distance round.

The other functional signs do not present anything very characteristic; the cough is variable and is in no wise peculiar, and the same remark applies to the dyspnoea, which depends more on the causative lesions than upon the bronchitis. Lastly, hæmoptysis is rare, and it never assumes the character that it presents in pulmonary gangrene.

With respect to the physical signs, all we can say is that if the foetid bronchitis supervenes on the top of bronchial dilatation, the physical signs are those of a bronchiectatic cavity and, in other words, the characteristic signs of foetid bronchitis are purely functional, the physical signs being common to bronchitis, whether complicated or not with bronchiectasis.

The general signs vary according to the stage of the disease. At the onset the general health may be pretty good, the temperature, raised to begin with, soon falls to normal, the appetite remains good, the tongue is not furred, the liver and spleen are not increased in size, and there is no albumin in the urine. In such cases the patient complains of nothing more than discomfort, and the whole history of the malady might be summed up in the words—foetid bronchitis. This benignity, however, is by no means the rule. The constitutional disturbance may be such as to threaten life, and, after a variable lapse of time, very grave complications may occur, especially pulmonary gangrene, the inevitable ultimate termination of most cases of bronchial gangrene.

But patients do not reach this terrible extremity all at once. Usually, after a time, the foetus of the breath and sputum subside, the general condition improves, and for weeks, months or even years the patient appears justified in believing that he is cured. This is, indeed, the characteristic intermittence, for the fugitive, ephemeral nature of the accidents is one of the most certain and constant signs of foetid bronchitis; it is also one upon which authors are least agreed. This question of intermittence brings us to that of curability. Pulmonary gangrene is but rarely recovered from, whereas in foetid bronchitis recovery is the rule. The cure, however, may not be permanent, and the patient may ultimately succumb to cachexia or lapse into genuine pulmonary gangrene with septicæmia.

When death is due to progressive cachexia it is caused by the absorption of the products of putrefaction and to the hectic fever to which this absorption gives rise. There is diarrhoea, first occasional, then chronic, the pulse becomes small and imperceptible, and death supervenes in marasmus.

In a certain proportion of the cases the gangrenous process does not remain limited to the bronchial mucosa, but extends to the pulmonary parenchyma, whereupon we get patches of broncho-pneumonia, with amphoric breathing, gurgling and pectoriloquy, which reveal the existence of huge cavities within. The general health fails, the complexion becomes sallow, the temperature reaches 103° or 104° and remains there, and the foetus of the sputum goes on increasing until death closes the scene.

The only disease for which foetid bronchitis can be mistaken is gangrene of the lung. In the majority of cases the diagnosis is easy enough. In the latter the onset is more violent and sudden, and the constitutional symptoms are altogether graver; there is no remission, and recovery is altogether exceptional. In the other, the disease assumes a chronic course from the very beginning, the patients give a history of having suffered for years from more or less copious catarrhal secretion, with a stale odour, though sometimes the foetus may be extreme, as bad, indeed, as in true pulmonary gangrene, so that we cannot trust entirely to this sign to distinguish between them. The microscopical appearances of the sputum are the same in both, for in both the expectoration tends to separate into layers when left at rest, and in both we find Dittrich's plugs. The special point in pulmonary gangrene is the presence in the sputum of pulmonary tissue, with or without elastic fibres, recognisable as such. Further assistance in the differential diagnosis may be obtained by studying the antecedents of the

patient, by watching the course of the affection and of the stethoscopic signs. Lastly, the almost invariably unilateral distribution, behind and to the left, the prolonged duration of the disease without manifest impairment of health, and apyrexia associated with the auscultatory signs of a pseudo-cavity from the beginning, without being preceded by symptoms of consolidation; all these are points that militate in favour of putrid bronchiectasis.

Bronchial gangrene may, however, merge into pulmonary gangrene, in which case we must rely for its detection upon the rapid deterioration of the general health, the progressive adynamia and the alteration of the physiognomy, on the supervention of high fever and the exaggerated foetus of the sputum, associated with aggravation of the cough and dyspnoea, in addition to evidence of disseminated foci of broncho-pneumonia. The possibility of its occurrence must always be borne in mind.

The prognosis in foetid bronchitis being grave, a very large number of therapeutical methods have been brought to bear—inhalations of turpentine water (Skoda), of carbolised water, sprays of solutions of tannin, of extract of rhatany, of sulphate of copper, perchloride of mercury, arseniate of soda—agents which, conveyed into the lungs, might conceivably act upon the diseased surfaces and expedite recovery. Leyden often made use of inhalations of oxygen associated with the internal administration of carbolic acid.

The only internal remedies that appear to do any good in foetid bronchitis are tincture of eucalyptus and hyposulphite of soda. Tincture of eucalyptus is recommended by Dr. Bucquoy, who gives it in doses of 30 minims daily. According to Lancereaux, the best remedy is the hyposulphite of soda in doses of a drachm daily. In five or six days its administration is usually followed by decided lessening of the foetus and a reduction in the amount of the expectoration. Chauffard prefers tincture of benzoin in doses of 10 to 15 minims daily, associated with essence of myrtle in doses of from 15 to 20 minims daily. There is no reason why we should not combine several of them in one mixture, for instance, tincture of eucalyptus, 15 minims; hyposulphite of soda, 1 drachm; mucilage, 12 drachms. To be taken in dessertspoonful doses every two hours. When internal treatment fails Dieulafoy has recourse to counter-irritation of the chest, and he has often obtained marked improvement in respect of the foetus thereby.

The practitioner, in treating foetid bronchitis, must, of course, not neglect to attend to the general health, which is apt to suffer in consequence of the copiousness of the expectoration, the possibility of the absorption of septic matter and the existence of fever, which may lead to cachexia and hectic. The health should be maintained as far as possible by the aid of tonics and reconstituents comprising easily assimilated preparations of iron, the glycerophosphates, and so on.

THE VITALITY OF THE TYPHOID BACILLUS IN SHELLFISH. (a)

By E. KLEIN, M.D., F.R.S.,
Lecturer on Advanced Bacteriology, St. Bartholomew's
Hospital, London.

THE following tables contain a summary of the results of six separate series of experiments. These were made in order to ascertain the behaviour of the *Bacillus typhosus* in oysters, cockles, and mussels, either when these were separately and directly infected with a definite quantity of the microbe or when they were kept for 24 hours in sea water previously infected with a definite quantity of the microbe:—

EXPERIMENT I.

Clean Burnham Oysters: Each oyster received into the interior of the shell a little over 160,000,000 of *B. typhosus*. Half of the number of these oysters

(a) Preliminary Report on investigations on behalf of the Worshipful Company of Fishmongers, London.

were then placed in clean sea water, which was changed every 24 hours; the other half was not placed in sea water at all, but was kept "dry" in a cool chamber. The first lot will be designated "wet oysters," the other lot "dry oysters." Each oyster received over 160 millions *B. typhosus*.

Lot 1.—Wet Oysters:—

Oyster 1—After 1 day—	70,000 <i>B. typhosus</i> per oyster.
" 3— " 2 days—	9,100 " "
" 5— " 3 " "	1,100 " "
" 7— " 4 " "	320 " "
" 9— " 6 " "	0 " per $\frac{1}{10}$ oyster.
" 11— " 7 " "	0 " " $\frac{1}{10}$ "

Lot 2.—Dry Oysters:—

Oyster 2—After 1 day—	1,200,000 <i>B. typhosus</i> p. oys.
" 4— " 2 days—	175,000 " "
" 6— " 3 " "	42,000 " "
" 8— " 4 " "	3,700 " "
" 10— " 6 " "	40,000 " "
" 12— " 7 " "	1,220 " "

EXPERIMENT II.

Clean Colchester oysters were placed in sea water; in this water typhoid bacilli of culture were distributed to the amount of 744,000 *B. typhosus* per 1 c.c. Twenty-four hours after oyster 1 was analysed and found to contain in its body 40,000 *B. typhosus*. Then the oysters were separated into two lots, lot 1 being placed in fresh, clean sea water, which was changed every 24 hours; lot 2 was kept "dry" as above.

Oyster 1 after 24 hours in infected sea water, 40,000 *B. typhosus*.

Wet Oysters:—

Oyster 3—After 1 day in clean water	1,380 <i>B. t.</i> per oys.
" 5 " 2 days " "	440 " "
" 7 " 5 " " "	82 " "
" 9 " 6 " " "	44 " "
" 11 " 7 " " "	0 " "
" 13 " 9 " " "	0 " "

Dry Oysters:—

Oyster 2—After 1 day dry	40,000 <i>B. typhosus</i> per oys.
" 4 " 2 days dry	3,700 " "
" 6 " 3 " "	700 " "
" 8 " 5 " "	150 " "
" 10 " 6 " "	280 " "
" 12 " 7 " "	510 " "
" 14 " 9 " "	90 " "

EXPERIMENT III.

Of experiment II, 10 oysters (6 wet, 4 dry) were left over. These, there was reason to suppose, had become practically free of *B. typhosus*, with which they had been originally infected. Both lots, wet and dry, were then kept for several days in clean sea water, and were then transferred to sterile sea water, to which culture of *B. typhosus* was added to the amount of 2,250,000 *B. typhosus* per 1 c.c. After 24 hours the number of *B. typhosus* was determined of the sea water and of one oyster of each lot—i.e., of the lot 1 "previously wet" and of lot 2 "previously dry." The sea water was then changed every 24 hours.

Sea Water:—

Immediately after infection	2,250,000 <i>B. t.</i> per 1 c.c.
1 day after infection	126,000 " "
1 day after change	250 " "
2 days " " "	0 per $\frac{1}{10}$ c.c.
3 " " " "	0 " "
4 " " " "	0 " "
6 " " " "	0 " "

Previously Wet Oysters:—

Oyster 15—After 1 day	84,000 <i>B. t.</i> per oyster.
" 17 " 2 days	935 " "
" 19 " 3 " "	105 " "
" 21 " 4 " "	0 per $\frac{1}{10}$ part of oyster.
" 23 " 7 " "	0 " "
" 25 " 8 " "	0 " "

Previously Dry Oysters:—

Oyster 16—After 1 day	1,318,000 <i>B. t.</i> per oyster.
" 18 " 2 days	1,900 " "
" 20 " 3 " "	646 " "
" 22 " 4 " "	713 " "

EXPERIMENT IV.

Polluted oysters from the foreshore of Southend-on-

Sea. The outside of the shell was well brushed and cleaned, and the oysters were then placed in sterile sea water in a tub, to which culture of *B. typhosus* was added to the amount of 2,470,000 *B. typhosus* per 1 c.c. In this infected water the oysters remained for 24 hours; then the sea water of the tub was tested, as also one oyster. The oysters were then taken out, the tub was well cleaned, and received fresh sterile sea water. The oysters were divided in two lots. Lot 1 were replaced in the clean sea water—"wet oysters." Lot 2 were not replaced in sea water, but were kept "dry" in cool chamber. The sterile sea water was changed frequently.

Sea Water:—

Immediately after infection	2,470,000 <i>B. t.</i> per 1 c.c.
24 hours " "	1,530,000 " "

" 10 " 11 " "	oyster looked abnormal, shell closed very slowly. Innumerable <i>B. typhosus</i> , very large number of <i>B. coli.</i>	

EXPERIMENT V.

Several dozen cockles were placed in sea water previously infected with *B. typhosus* of culture to the amount of four millions per 1 c.c. After 24 hours the cockles were taken out and washed; two were retained for analysis, the rest were transferred to clean sand wetted with clean sea water. This change—*viz.*, placed into clean sand wetted with clean sea water—was repeated several times in the course of ten days. The two cockles above referred to, which were examined 24 hours after having been kept in the typhoid-infected sea water, showed that each contained in its body about half a million of *B. typhosus* (120 *B. coli*).

Cockles 1 and 1a, after 24 hours in infected water,	contained each about 500,000 <i>B. t.</i>
Cockle 2, after one day's change,	contained 153,000 <i>B. t.</i> (no <i>B. coli</i>).
Cockle 4, after two days' change,	contained 382,000 <i>B. t.</i> (no <i>B. coli</i>).
Cockle 6, after five days' change,	contained 358,000 <i>B. t.</i>
Cockle 8, after six days' change,	contained 1,541,000 <i>B. t.</i>
Cockle 10, after seven days' change,	contained 138,600 <i>B. t.</i>
Cockle 12, after nine days' change,	contained 69,300 <i>B. t.</i>
Cockle 12a, after nine days' change,	contained 111,000 <i>B. t.</i>
Cockle 14, after ten days' change,	contained 1,600 <i>B. t.</i>
Cockle 14a, after ten days' change,	contained 69,000 <i>B. t.</i>
Cockle 14 was not quite normal; its shell did not close well.	

EXPERIMENT VI.

Several dozen mussels were placed in sea water infected with *B. typhosus* of culture to the amount of 5,170,000 *B. typhosus* per 1 c.c. Having been kept for 24 hours in the infected sea water, the mussels were washed in clean sea water; one was kept back for analysis, the remainder were transferred to a fresh clean tub with sterile sea water covered with seaweed. In this water the mussels remained for about six hours, after which time the bulk of the water was poured off,

leaving just sufficient to keep the mussels in the tub in a wet condition. By doing this we tried to imitate to some extent what occurs under natural conditions—*viz.*, mussels are not permanently immersed in the water like oysters, but during ebb remain uncovered by water. This same process—*viz.*, clean tub with fresh sterile sea water for six hours—was repeated every 24 hours as long as any of the mussels remained alive.

Mussel 1 (large), kept in infected sea water for 24 hours, contained over six millions *B. typhosus*.

Mussel 2 (medium sized), one day after change, contained 74,800 *B. t.*

Mussel 3 (large), two days after change, contained 628,660 *B. t.*

Mussel 4 (medium), three days after change, contained 36,000 *B. t.*

Mussel 5 (medium) five days after change, contained 58,450 *B. t.*

Mussel 6 (medium), six days after change, contained 6,250 *B. t.*

Mussel 7 (medium), seven days after change, contained 14,200 *B. t.*

All these mussels were in good condition, looked in every way normal, shell well closed. The experiment could not be continued on account of the difficulty of keeping them alive and normal. From the foregoing experiments I would draw the following conclusions:—

1. Oysters readily take up into their interior the *B. typhosus* which had been introduced into their shell or into the surrounding sea water.

2. Oysters, clean at starting, rapidly clear themselves of the ingested *B. typhosus*, if they are kept in clean sea water which is frequently changed.

3. Oysters, clean at starting, clear themselves of the ingested *B. typhosus* to a less extent and slower, if they are kept in a "dry" state—*i.e.*, out of the sea water.

4. Oysters from a polluted locality clear themselves of the ingested *B. typhosus* to a less extent and at a slower rate, even if kept in clean sea water, than oysters clean at starting.

5. Oysters from a polluted locality retain the ingested *B. typhosus* to a markedly larger extent if kept "dry"—*i.e.*, outside the water.

6. The process of "clearing themselves" of the ingested *B. typhosus* cannot be owing to the oyster merely "passing out" the ingested *B. typhosus*, but must be due to a large extent to an inherent power of the oyster of *directly devitalising the microbe*. The experiments with the "dry" oysters prove this, and it is also evident from the rapid rate at which this microbe disappears from the oysters kept in clean water if compared with the very small number of the microbe (*B. typhosus*) found at the same time in the surrounding sea water. (Experiments III and IV.)

7. Oysters which had been infected with *B. typhosus*, and which were then kept in a "dry" state till they had practically cleared themselves of the microbe, when subjected to re-infection with *B. typhosus* appear less capable of dealing with this microbe, even if they be kept in clean sea water, than the re-infected oysters which have always been kept in the water. This could be explained by the obvious supposition that oysters by being kept for some days out of the water, are not possessed of the same degree of vitality and activity of their tissues as oysters are which have always been kept under normal conditions—*i.e.*, in water.

8. Oysters from a polluted locality, and containing a large number of *B. coli*, very rapidly clear themselves of this microbe, both those kept in, as also those kept out of the water. This shows that *B. coli* is foreign to the oyster and is rapidly destroyed by it. (Experiment IV.) When, therefore, it is present in the oyster, it must have been derived from the surroundings.

9. However largely infected with the *B. typhosus*, the oysters at no time present to the eye any sign of such infection; they remain in all parts normal in aspect. This is the case not only with the infected oysters kept in sea water, but also with the infected oysters kept in the "dry" state. There was only one

exception—*viz.*, an oyster derived from a polluted locality, which oyster had been eleven days out of the water.

10. During the time of these experiments (part of September, October, and part of November) the oysters lived quite well in *sterile* sea water frequently changed. There was no alteration noticeable in the aspect of the fish; they remain plump and juicy, and capable of promptly and tightly closing the shell.

11. Cockles readily embody the *B. typhosus* present in the sea water. While the number of these latter appears at first to diminish in the body of the cockle, it soon increases to a considerable degree, for five days after the cockles had been removed from the infected water and kept in clean sand the number of *B. typhosus* exceeded three times the number initially present. Their subsequent diminution proceeded only slowly, since even ten days after their removal from the infected water the cockle examined still contained in its body 69,000 *B. typhosus*.

12. Mussels also readily embody the *B. typhosus*; in fact, the analysis seems to show that mussels do so to an extent greater than oysters or cockles. As regards the fate of the *B. typhosus* in the mussels, these appear to stand between oysters and cockles, since in mussels the *B. typhosus* undergoes gradual diminution, but this diminution is incomparably slower than in oysters, but takes place somewhat quicker than in cockles.

Clinical Records.

CASE OF FOREIGN BODY IN ŒSOPHAGUS.

Under the care of JOHN REID, M.D., B.Ch., B.A.
Bandon.

THE following case of a foreign body in the œsophagus is, I think, interesting from one or two unusual features—*viz.*, the size of the foreign body which could be swallowed to a certain distance by a young child; and also the absence of symptoms two weeks after the occurrence to denote the presence of such a body. A child of barely four years was brought to my study with a history of having swallowed a penny twelve days previously. Being doubtful, I asked the father if anyone saw the penny disappear, and he stated that his wife and mother-in-law were there at the moment, and that they tried to get the coin out of the child's mouth, but could not, and that he immediately became dark in colour from choking. The child vomited five or six times in twenty-four hours for the first few days, but the penny was neither vomited nor passed per *vias naturales*.

I wished to pass a bougie into the œsophagus to solve the problem, but was not allowed. To show how a patient may get accustomed to a foreign body, the vomiting ceased altogether, and the child could eat everything, except that occasionally he complained that pieces of bread or buttered toast hurt him. He was well nourished, being both fat and ruddy. It seemed strange that with such a history he was able to take any solid food he liked, and only sometimes complained.

External palpation revealed nothing, and there was no bulging in the neck.

Judging it to be a most suitable case for the purpose, I resorted to skiagraphy to inform me whether a coin was in the œsophagus or not, and its exact localisation. The accompanying radiogram—for which I am indebted to Messrs. Wyatt and Sunner—shows the coin and its position just behind the cricoid cartilage. Under chloroform, assisted by my friend and colleague, Dr. Welply, I passed a coin-catcher down the gullet, and soon felt a grating, reminding me of sounding for stone in the bladder; with a little difficulty I succeeded in extracting the coin, and the child was running about next day as well as ever, and able to eat its ordinary food.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.
MEETING HELD MARCH 10TH, 1905.

The President, DR. FREDERICK TAYLOR, in the Chair.

MR. JAMES BERRY showed a case of a man, *æt.* 33, on whom he had performed a rhinoplastic operation for syphilitic necrosis.

A CASE OF ACUTE RHEUMATOID ARTHRITIS.

DR. HALE WHITE read notes of a case of a woman, *æt.* 25, illustrating this disease, and said that it and other cases made him suggest that from among the diseases which are often grouped together under the

joint is frequently implicated and mastication is consequently difficult. Wherever the disposition of surrounding muscles makes it easy to investigate the joints, swelling about them is obvious and the patient usually complains of pain in them. Muscular wasting is so very rapid that it is clearly an extreme degree of genuine arthritic atrophy and not dependent on disuse; the wasting is especially seen in the hand and forearm, but in a bad case it is almost universal. The temperature is often raised daily, mostly in the evening, to a point usually between 100° and 102° F. The hands and feet are often covered with sweat while the rest of the body is quite dry; the patient is pale and the pulse is increased in frequency out of proportion to and apart from pyrexia, although neither from the history nor from the examination of the heart is there any

RADIOGRAM OF DR. REID'S CASE OF FOREIGN BODY IN ŒSOPHAGUS. (See *Clinical Records*.)

names of chronic rheumatoid arthritis, osteo-arthritis, arthritis deformans, and chronic articular rheumatism, there is one which should be sharply separated off as a distinct disease. It has, he believed, the following characteristics: It is usually met with in women whose age is most often near to twenty; the disease begins, or is, at any rate, soon most prominent, in the proximal phalangeal joints, and is quite early strikingly seen in the wrists; it is markedly symmetrical in the two hands, the swelling is considerable and extends beyond the joints so that there is a well-marked fusiform swelling about the affected inter-phalangeal joints and a general swelling about the wrists and other joints; sometimes a creaking may be felt, due apparently to thickening of the synovial membrane. In the course of a very few weeks most of the joints in the body are affected, so that the woman is soon bedridden, unable to move fingers, thumbs, wrists, elbows, shoulders, and the corresponding joints of the lower extremity. The joints of the spine are often affected so that turning in bed is difficult and painful; the temporo-maxillary

evidence to connect the disease with rheumatic fever. Sometimes a number of brown spots like large dark freckles appear on the face, body, and limbs. After two, three, or four, or even six weeks the temperature slowly regains its normal point, the rate of the pulse diminishes, but more slowly than the temperature. The colour partly returns, the sweating of the hands and feet lessens, the pain passes away, but much immobility and some swelling around the joints remain, and the patient is liable to fresh attacks which exactly resemble the first, and result in fresh swelling of and around the already fixed joints. After the acute stage has subsided the sufferer is by no means recovered, for the swelling of the synovial membrane and soft tissues around the joints leads to great immobility of them, and much of the muscular atrophy remains. The patient is hence often a chronic invalid. In this respect, as well as in many others, the disease stands in striking contrast to rheumatic fever. Careful manual examination during life, even in cases which have lasted many years, fails to reveal any lipping or

bony outgrowths in connection with the joints. The deformity appears to be entirely due to effusion into the joint and swelling of the tissues around. Radiographic examination confirms this view. As a rule, the attacks diminish in severity as time goes on and ultimately the patient may only suffer from the deformities due to previous attacks. Dr. Hale White next described the histology of the disease and showed that it undoubtedly originated in the synovial membrane and tissues around the joint, and that no changes occurred in the bone and cartilage except such as might be produced by pressure of thickened synovial fringes. He then described an individual case and pointed out the importance of passive movements in order to prevent fixation. He showed that the bones were unusually transparent to the X-rays, and, lastly, discussed its relation to other diseases, maintaining that it was a distinct disease for which the most convenient appellation would be acute rheumatoid arthritis.

Dr. BERTRAM ABRAHAMS read a paper on

ARTHRITIS DEFORMANS AND ITS ALLIES.

The expression, "arthritis deformans," is selected as the least unscientific of the many names—Putnam in his recent monograph quotes twenty-one—for the disease, and that in most general use on the Continent and in America. There are four chief maladies which are grouped under this head. Of these, that described by Still in children stands entirely apart by reason of its course, the sequence of joints affected, and the associated enlargement of the spleen and lymphatic glands. At the other end of the scale is senile osteo-arthritis, which is a degenerative process that may come on as the terminal phase of arthritis deformans, or quite apart from it as a senile change in normal joints or in those already crippled by true rheumatism. The two remaining affections—acute and chronic arthritis deformans—are, it is suggested, different forms of the same malady, which is in all probability of an infective or at any rate toxæmic nature. In the acute type the poison is in such considerable amount that a large number of joints are, so to speak, flooded with it, and simultaneously affected; in the chronic the intoxication is less severe, but more prolonged, so that the morbid changes are more in the nature of degeneration than of inflammation, and the joints are picked out in a fairly definite order. At the same time, as is only to be expected, much of the brunt of the disease falls upon the nervous system. That the two types merge into one another is further indicated by the number of intermediate forms which are met with. Skiagrams and photographs were shown of the following conditions:—Gonorrhœal arthritis, Charcot's joint, acute arthritis deformans, chronic arthritis deformans, and Still's disease.

Dr. TOOGOOD was very familiar with Dr. Hale White's acute cases, but thought that they were just as commonly met with in men as in women. He remarked on the difficulty in diagnosis between them and gout. In his opinion no drugs were of any avail in the condition. The senile form of the disease, in which fibrillation and other degenerative changes were found in the cartilages, was to be found in nearly all *post-mortems* over sixty. That morning he had examined the joints of a gouty patient which were of this nature; in fact, in his experience, gouty joints always showed these changes. The specimens were exhibited.

Dr. A. E. GARROD welcomed this occasion, for the subject was one that urgently demanded discussion. In addition to the features mentioned by Dr. Abrahams as marking off Still's disease was its comparatively high mortality, whereas the adult cases rarely died. He had found the presence of enlarged spleen and gland to be rarer than Dr. Still originally described. In the adult, leaving on one side the senile complaints, two diseases could be clearly discerned. First, we had Dr. Hale White's acute rheumatoid arthritis, and he would here refer to these cases, which were subacute in their course, progressing steadily for years, and even more disabling than the acute cases. Then there was the multiple osteo-arthritis. This was characterised by a quite different distribution, often implicating the

thumb carpo-metacarpal joint, showed the osteo-phytic changes, and cause far less damage. He suspected the existence of a third condition in which deformity was the prominent feature, this being out of all proportion to the joint enlargement. This deformity could be averted by massage, whereas that due to the other forms could not. There were other cases due to diverse infection, such as the pneumococci, and these caused great difficulty in diagnosis. The confusion that existed was largely due to the infrequency of *post-mortem* examinations. The infection in the rheumatoid cases was very often a puerperal one, this accounting for the frequency of the complaint in women. Grating might be felt distinctly at times, especially in the knees, indicating erosion of the cartilages. Treatment was more efficacious in the osteo-arthritic cases, except in the form seen in single joints.

Dr. A. P. LUFF also thought that several different diseases had been included under the same name. He believed strongly that the infection took place by the alimentary tract, and was convinced of the high value of intestinal antiseptics, notably of carbonate of guaiacol. In the distribution of the lesions he remarked that the acute cases affected the proximal interphalangeal joints, and the chronic the thumb-joints. In the diagnosis between the condition and gout, the two most important points were the symmetry of the former and the sweating or clamminess of the palms and soles. The cervical vertebræ and the temporo-maxillary joint were rarely affected in gout. He commented on the very rapid advances made of late years in the treatment of the conditions. He did not think that the single joint, such as the hip, type of case was of infective origin, but was a traumatic form of osteo-arthritis; monarticular rheumatoid arthritis was therefore a bad term.

Dr. PRESTON KING commented on the advance in knowledge that had occurred as a result of the Cheltenham meeting. Dr. Spender, of Bath, had first pointed out the rapid pulse, the sweating of the palms, and other characteristic features. He did not think that the X-rays were of any value in the diagnosis from gout. That there was a strong nervous factor in the disease was undoubted; it was instanced by the muscular atrophy and the vaso-motor symptoms, such as rapid pulse. He regarded the condition as a result of the action of the rheumatic virus on the nervous system of resistant persons.

M. BLANC, of Aix-les-Bains, related two severe cases that had contracted diphtheria and had been cured of the joint conditions by antitoxin. In ten cases he had used the treatment and improvement had always resulted, with complete cure in two of them. As he rarely had the opportunity of trying its effect apart from bath treatment, he recommended it to those interested as being worthy of further observation. As regards diagnosis, the main difficulty was not in excluding gout, but in distinguishing between the two forms of rheumatoid arthritis.

Dr. WM. EWART was of opinion that the toxic origin of the conditions is now established, though the number of such toxins was legion. The actual poison was more likely to be that secreted by microbes than the microbes themselves, and might indeed be autotoxins. He used the analogy in this connection of the joint changes seen in bronchiectasis. He was at present getting good results by varying the blood supply to the part so as to produce alternate anæmia and hyperæmia.

Dr. LLEWELLYN JONES, of Bath, saw very little difference between the acute and the chronic cases; the temperature ran a similar course in both. Might not the rapid pulse-rate be an indication of a larval form of Graves' disease? This condition was frequently associated; he had seen over twenty such cases, and it was one of the evidences of the close connection between the nervous system and rheumatoid arthritis. In the past year he had seen six cases in which rheumatoid arthritis had followed on gastric ulcer. He referred to various prodromal symptoms, such as local syncopal and asphyxial attacks, cramps, &c. He had been struck by the segmental distribution

of the lesions, thus the ring and little finger were usually affected together, and the thumb and index finger. McCrae had noticed the same thing.

Dr. HALE WHITE, in reply, agreed that the condition he had described was not rare in men. As regards the transparency of the ends of the bones and the fusiform shape of the swelling, he recognised that both occurred in other conditions, but as they were never absent in this disease, their presence or absence was of importance in diagnosis. With regard to the grating observed by Dr. Garrod, he acknowledged that destruction of the cartilage occurred, but emphasised the fact that it was, in these cases, always secondary to the synovial mischief. He was very sceptical as to the power of any drug to disinfect the alimentary canal.

Dr. BERTRAM ABRAHAMS, in reply, agreed with Dr. Luff as to the great value of guaiacol, but could not attribute this to its antiseptic properties, seeing that it was the only member of the group that possessed such beneficial effects. He was interested in M. Blanc's remarks on diphtheria antitoxin, as, ten years ago, he had seen Dr. Sydney Ringer treat several cases with it, and in one case with markedly beneficial results.

ROYAL ACADEMY OF MEDICINE IN IRELAND. SECTION OF SURGERY.

MEETING HELD FRIDAY, FEBRUARY 24TH, 1905.

MR. E. H. BENNETT, F.R.C.S., in the Chair.

EXHIBITS.

MR. L. A. BYRNE exhibited patient after operation for epithelioma of the tongue; also the part removed.

SIR LAMBERT H. ORMSBY exhibited patient whose olecranon had been wired after fracture.

MR. G. JAMESON JOHNSTON exhibited patient who had the power of voluntarily producing a partial dislocation of the knee.

MR. W. I. DE C. WHEELER exhibited an extension apparatus for fractured femur.

MR. BLAYNEY exhibited (a) parts removed in the treatment of acute intussusception, and (b) malignant disease (colloid cancer) of the large intestine.

THE APPLICATION OF PLASTER OF PARIS TO FRACTURED FEMUR FACILITATED BY A NEW APPARATUS.

MR. W. I. DE C. WHEELER exhibited an apparatus designed by himself to facilitate the application of plaster of Paris, either as a primary dressing to fractures of the femur, or at any period before union had taken place, a full description of which we published last week.

MR. E. H. BENNETT was of the opinion that the apparatus was probably useful in general hospital work, but could hardly be used by country practitioners.

MR. TOBIN thought that Mr. Wheeler's method would be useful in the treatment of fractures of the femur in field service.

MR. W. S. HAUGHTON considered the device both simple and efficient. It saved labour, made the subsequent nursing simple, and saved the surgeon paying numerous visits.

MR. KENNEDY also discussed the communication.

MR. WHEELER, in reply, stated that the apparatus was very portable, was by no means difficult to make, and cost about two pounds.

OBLIQUE FRACTURE OF THE TIBIA.

MR. EDWARD H. BENNETT read a paper on this subject, and illustrated his observations by a series of skiagrams. He stated that fracture of the tibial shaft alone was rare as a result of indirect violence, although common enough when the violence acted on the bone directly. Oblique fractures of the central portion of the shaft without accompanying fractures of the fibula are rare. He then related the history of a case which recently came under his notice. The patient, a young girl, *æt.* 15, jumped from a height of about twelve feet on to the ground and immediately fell backwards. Although she was able to stand up she could not put any weight on the injured limb, nor attempt to walk. On being brought to hospital soon afterwards she was

found to be suffering from pain, and complained of loss of power in the limb, but it was not possible to obtain crepitus, nor detect any evidence of abnormal motion in the limb. An X-ray examination, however, revealed the presence of a fracture. It was very oblique, traversing almost four inches of the shaft of the tibia in its middle segment. Its direction was from above and without downwards and inwards. The progress of the case was uneventful, and union was perfect in the ordinary time. The absence of deformity was explained by the integrity of the fibula. The skiagrams obtained from this case afforded the only example he had seen of oblique fracture of the shaft of the tibia only from indirect force.

MR. HAUGHTON expressed himself deeply indebted to Mr. Bennett for the information he had derived from him on the subject of fractures. In studying the long bones stereoscopically one found that the oblique direction of the lamellæ was the rule and not the exception, and that when one regarded fractures from the anatomical standpoint it could be seen that their planes ran parallel to the direction of these bone lamellæ.

The communication was also discussed by Mr. Tobin, Mr. Edward H. Taylor, and Mr. Jameson Johnston.

SOME CASES OF JOINT EXCISION.

MR. KENNEDY read a paper on the above. One case of excision of the knee was remarkable, as the joint was riddled with sinuses, fixed at right angles for years, and the patient showed symptoms of well-marked phthisis, a cavity being present in one lung. Nevertheless recovery quickly followed operation, the lung healing rapidly, and the patient was enabled to get about. In connection with this case Mr. Kennedy dwelt on the importance of fixing the bones together after excision of the knee by Tobin's clamps or by suturing. A case of excision of the shoulder, and one of excision of the elbow, were quoted as examples of dry caries of the articular ends of bones. Although in each the disease was present for years, not a trace of suppuration was present in either. The diagnosis was difficult, and was made clearer by skiagraphy. Mr. Kennedy also quoted the case of a child, *æt.* 4, who had met with an accident producing an epiphyseal separation of the upper end of the humerus. At the operation the articular head was found completely detached from the rest of the epiphysis. The head was removed, and the remainder of the epiphysis sutured to the diaphysis. Complete union followed, although fifteen months had elapsed from the time of the accident to the operation. The child has perfect motion in her arm, and the growth of the limb has not been interfered with.

MR. BENNETT congratulated Mr. Kennedy on the first of his cases—*viz.*, that in which an excision of the knee had been successfully performed in a patient who had symptoms of a phthisical cavity in one lung.

MR. TOBIN had seen some of Mr. Kennedy's cases. The first of these which had just been recorded was one which few would have cared to undertake.

MR. HAUGHTON discussed the diagnosis of early tuberculosis of joints by the aid of X-rays, and gave it as his opinion that a positive diagnosis could be made if the disease had been present for some weeks. Stereoscopy was of great value in these cases. By its aid areas of rarefaction could be discerned, and their true relations to each other and to the joint made out.

In reply, MR. KENNEDY expressed his sense of obligation to Mr. Haughton for his hints as to diagnosis, as cases often cropped up in which it was far from easy to say if bone disease was really present.

Trinity College, Dublin.

The following passed the final in Midwifery at Hilary Term, 1905:—Robert Magill, Michael J. M'Auliffe, George E. Nesbitt, Cecil Scaife, Edward G. Scroope, John A. Pringle, John W. Burns, Joseph W. Houston, Richard Kelly, Robert A. Askins.

The following candidates have passed the final in Surgery at Hilary Term, 1905:—Henry E. M'Cready, Robert Magill, Michael J. M'Auliffe, and Edward G. Scroope.

ASSOCIATION OF MEDICAL DIPLOMATES OF SCOTLAND.

MEETING HELD MARCH 10TH, 1905.

MR. CLAUDE ST. AUBYN FARRER in the Chair.

THE EXCLUSION OF PROVINCIAL QUALIFICATIONS FROM HOSPITAL APPOINTMENTS IN LONDON AND ELSEWHERE.

THE PRESIDENT said that some present no doubt had experienced the disability of not having an English Fellowship, who, in spite of their skill and ability, had been thus debarred from an appointment. Our notice refers to "Disabilities enforced against provincial medical qualifications in many London and some Provincial Hospital Appointments."

"Now, I propose to draw attention to those disabilities with regard to the Scottish colleges. It is a fact that a number of the hospitals in London exclude Fellows of the Scottish colleges from holding appointments in these institutions. In an able article in THE MEDICAL PRESS AND CIRCULAR of March 1st, I read that the Royal Orthopædic Hospital originally did not exclude surgeons from its staff having other than English qualifications. Now according to the amalgamation scheme with the National Orthopædic only surgeons holding a diploma from an English College are admitted. This to my mind is a great injustice and why, I ask, should these things exist? Who is responsible for it? What have the Hospital Funds to say on that point? Is it contended that the examinations for the excluded diplomas are inferior in scope or severity as compared with the corresponding ones of the English colleges? Look at the syllabuses and compare them; they are similar. Again look at those holding these diplomas and who are fortunate enough to hold hospital appointments in London. In my humble opinion, and as far as I am able to judge, and I could name many, even some who are amongst us to-night, whose knowledge and skill and sound judgment would certainly eclipse others who, sometimes, are simply chosen because they have the English Fellowship. It seems to me that no examination or series of examinations beyond a certain stage can be a gauge of a man's capabilities. It is the man himself who ought to be chosen for these appointments, provided he has, say, a Fellowship of his college. Some men are good at passing examinations, but in other respects may be failures. Able physicians and surgeons are born not made by examinations. Let these able men who have proved themselves as such be elected irrespective of college (English or Scottish) or creed. The hospitals and the public will be the gainers by this arrangement. Why should the portals of some of our hospitals be closed against capable qualified men? Does not this savour of monopoly? Are not the hospitals supported and the Funds derived from all, irrespective of country? The management committee does not say only English may subscribe. Have not others given largely and generously to the help and support of these splendid institutions? The hospitals in the provinces are, I believe, as great or greater sinners in this respect than London, but possibly they take their cue from London, and follow suit only in a greater degree. I think you will agree that this evil (shall I call it?) exists. I have given a typical instance of recent date; only one out of numbers it is true, but sufficient for my purpose. Now as to the remedy or remedies, I hope that in the papers and discussions to follow some practical way may be pointed out these wrongs may be righted."

Dr. HARDYMAN (Bath) congratulated the Association on having, at their first meeting, taken up the important subject of the disabilities of medical diplomates of Scotland and Irish diplomates in the hospitals of England. An ounce of fact was worth a ton of theory. He would therefore read some illustrative rules:—

"Every candidate for the office of honorary assistant physician shall be a graduate of medicine of one of the Universities of Great Britain or Ireland, and every candidate for the office of honorary assistant surgeon shall hold the diploma of M.R.C.S. England." Why?

"The resident medical officer shall hold the conjoint diploma of the M.R.C.S.Eng. and L.R.C.P. London, or be a graduate in medicine of a University of Great Britain or Ireland. The house surgeon shall hold the diploma of M.R.C.S.Eng." Why?

Again. "Every honorary physician shall be a graduate in medicine of one of the Universities of Great Britain or Ireland and a Fellow or Member of a British or Irish College of Physicians, and every honorary surgeon shall be a Fellow by Examination of a British or Irish College of Surgeons, but in the event of a candidate not possessing in the former case a Fellowship or Membership of a College of Physicians, or in the latter case a Fellowship of a College of Surgeons, an engagement on his part to obtain the same in each instance respectively, within two years from the date of his appointment, shall be accepted."

Now these rules cut out Scottish and Irish diplomates from a public institution, when such restrictions might prevent the best local men from being appointed. In this same town there is another hospital, older and larger, with three honorary physicians and three surgeons where the appointments are open. Out of these six, four hold Scottish diplomas and the previous senior physician held an Irish one. In the former hospital above mentioned, it might be said that the hon. surgeon may hold office through the F.R.C.S.Ed., and that it does not say that he requires to be a M.R.C.S.Eng., but an assistant surgeon is always chosen, and that by seniority, to hold the office of hon. surgeon. What is the cause of this ostracism? Is it that our diplomas are so poor that they cannot compare with the English diplomas? or that the Scottish training produces men too good to be competed with on equal professional terms? If it is the former there is surely no need to fear competition—if the latter, then they do the hospitals a grievous injury. Who keep out the Scottish diplomates? They are the English diplomates and not the lay members of the hospital committees. In the Scottish hospitals the English diplomates are welcomed if they are good enough in other ways for appointment. How were our grievances to be remedied? We must be united and hold high scientific and ethical ideals. We must get all the might and authority we can on our side through our colleges and Universities. There were many rocks ahead, one being that the hospital appointments are in the hands of different committees all over the country, who are difficult to appeal to and still more difficult to impress with the justice of our cause because they naturally turned to their professional staff for advice. These committees have to be fought *seriatim*.

Dr. DAVID WALSH said that the disabilities attached to certain medical qualifications in the tenure of many hospital appointments was a grievance of old standing. Medical men were realising the importance of self-government. At present medical men are at the mercy of a General Medical Council and of a number of qualifying corporations, all more or less absolutely autocratic and careless of the general interests of medical men. The subject of hospital disabilities had been systematically dealt with by the Irish Graduates' Association, founded about 1878 or 1879 with James Thomson, of Leamington, as Honorary Secretary. The name of the Society was changed in 1885 to that of the Irish Medical Schools' and Graduates' Association. On June 21st, 1888, on the proposition of the President, Professor MacAlister, F.R.S., seconded by Sir George Paget, K.C.B., a statement was ordered to be printed for circulation among lay governors of hospitals, setting forth the arguments against such limitation. On March 17th, 1889, Dr. Macnaughton-Jones, the then president, stated that they "had done much to remove the prejudices and the disabilities for hospital appointments which exist against Irish graduates in England." It was the aim of the Scotch Diplomates' Association to gain equal treatment for Scotch qualifications in every part of the United Kingdom. In 1890 Mr. James Stewart, of Clifton, stated that these disabilities against Irish and Scotch diplomates were enforced in sixty-eight

large public hospitals and infirmaries in England. Also that under a similar condition the then Director-General of the Royal Navy would have been ineligible. At that time there were 486 Irish diplomates in London. At the present moment there were 830 Scotch diplomates in the metropolis. A serious permanent disability, therefore, is inflicted upon some 1,200 medical men in London alone. The essence of the position was that exclusion of outside diplomates from hospital appointments enhances the value of the diplomas of the London Royal Colleges. The provincial diplomates were therefore ousted from a fair chance of reaching the top of the tree, or at any rate they were enormously handicapped in a London career by being excluded from the large hospitals. The London colleges had by exclusion enhanced the value of their qualifications, for which they already charged exorbitant fees. The traditions and management of the London colleges savoured of mediæval class privilege and were absolutely out of touch with such leading principles of modern thought as those which insisted upon equality of opportunity for all men and upon government by consent of the majority. Of all the mediæval survivals still clinging to the London colleges there was none more offensive and grotesque than that which excluded the diplomates of rival colleges from the great hospitals of the metropolis. The first step towards a remedy was publicity of the facts of the case, as for instance by circularising governors of hospitals. The General Medical Council had declined to act in the matter. The colleges of the excluded diplomates, however, might enter standing protests. Money, of course, was needed to cover the expenses of organisation. Pressure, too, should be brought upon the Metropolitan Hospital Funds. Quite recently an audacious attempt had been made to make two of those Funds catspaws in extending hospital disabilities to two hitherto open institutions. The standards of the London colleges were not necessarily the highest and the most successful in turning out able and original men. The fellowship of the London Physicians was an honorary qualification, conferred upon many young and unknown men but withheld from the late Dr. MacLagan, who had introduced the salicylates in the treatment of rheumatism. The *Register* alone should be a sufficient qualification for hospital service.

Mr. J. LENNANE remarked that there was no need to make invidious comparisons as to the relative value of London and provincial qualifications. The exclusion of Scotch and Irish diplomates was not settled on that score. The essence of the thing was that no Scotch or Irish need apply.

Dr. MACNAUGHTON-JONES, speaking as one of the visitors, and also as a Fellow of the Edinburgh College of Surgeons, said that for years the Irish Medical Schools' and Graduates' Association had taken the matter up, with the assistance of men like Prof. Gerald Yeo and the late Sir Thomas Crawford, with other distinguished Irish diplomates. They had so far succeeded that at three annual meetings of the British Medical Association this monopoly of hospital appointments was condemned, first at Dublin, next at Glasgow, and again at Bournemouth. At Bristol, at the East Sussex Hospital, and at Tunbridge Wells this disability rule had been rescinded. The Association had also sent a statement to the governors of all the principal hospitals in England and Wales, and had endeavoured to arouse the active interest of the Royal Colleges of Ireland. This exclusive condition might be looked at from three points of view: Its effects on the interest of the State, its effects on the public at large, and, lastly, on the medical profession. It could not be for the good of the State to hamper progress by placing a drag on ability, and robbing its servants of opportunity. Opportunity makes many men, but it is given to few men to make opportunity! Hospitals were often the sole opportunities of surgeons. Deprive them of these, and you take from them their only chances of arriving at distinction and eminence. Thus the State is deprived of an unknown quantity of able men, and the possibilities which only now and

then arise from the gift of genius. As to the public and the sick poor, for whom hospitals were intended, what must be their loss by the shutting out from all competition of a large proportion of the medical profession? If we looked to the public services, we should find that the highest posts in these were frequently held by Scotchmen and Irishmen. A late Director-General of the Navy was an Irish diplomat, and before his time it had been held by a Scotchman—Sir James Reid. The present Director-General of the Army Medical Service and the heads of the Indian Medical and Netley Departments were Irish graduates. The most brilliant modern work in medicine and surgery had come from Scotland and Ireland. There were at the present moment in Scotland some of the most famous and illustrious of living surgeons. Were they to be told that those holding the highest qualifications of the Scotch and Irish colleges were incompetent to fill the position of surgeon to an English hospital? If not, then on what ground, save that of a jealous monopoly, were diplomates of these colleges boycotted in the English hospitals?

Dr. FITZGERALD POWELL said the *locus standi* of the London colleges was that their standards of examination were higher than those of the outside colleges. The public were certainly informed to that effect. The question was, therefore, how were the public to be put in possession of the real facts of the case? They must appeal to the Scotch and Irish colleges and ask them to make it known if their standards were equal to those of London, and, if not, to make them equal.

Dr. HERSHELL remarked that the real reason of the exclusion of certain qualifications was that a London hospital appointment was the only avenue to lucrative consulting practice. To exclude Scotch and Irish diplomates was to exclude two-thirds of the effective competition.

Mr. CANNY RYALL narrated some personal experiences of the injustice inflicted by the excluding regulations. As a teacher he maintained a man could pass the English Fellowship examination in anatomy without having dissected a body.

The following resolution was proposed by Dr. HARDYMAN, seconded by Dr. FITZGERALD POWELL, and carried unanimously:—"That this Association of Medical Diplomates of Scotland records its regret that so many English public hospitals have still among their regulations a rule the effect of which is to exclude from candidature for honorary appointments on the staff all who do not hold the diploma of two specially favoured London colleges, and that this Association pledges itself to do all that lies in its power to remove this injustice."

Mr. SYDNEY STEPHENSON asked what was to be done to give force to the resolution. After some discussion, he proposed a resolution, seconded by Dr. S. LIGHTFOOT, and unanimously adopted, that a copy of the former resolution be sent to hospital secretaries and chairmen concerned throughout the Kingdom, and to the Hospital Funds.

The meeting then terminated.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

MEETING HELD THURSDAY, MARCH 9TH, 1905.
JOHN TWEEDY, P.R.C.S., President, in the Chair.

CLINICAL EVENING.

Mr. EDGAR CHATTERTON showed a woman, æt. 38, who had the inner canthi, caruncles and innermost extremity of the lower palpebral conjunctivæ discoloured and of a dark grey appearance. As far as she knew this appearance had always been present. She had never had her lids treated with anything, neither had she any sign of old disease. Her occupation consisted of filling toy crackers with fulminate of silver and she had done this work for years. Mr. Chatterton suggested that the silver salt had got into the eye and had caused the discoloration shown.

Mr. CHARLES BLAIR showed a case of "Retinitis

Proliferans" in a woman, *æt.* 59. The vision of the left eye was suddenly lost six months ago. The right fundus showed changes suggestive of albuminuria with numerous retinal hemorrhages. The urine was, however, free from both albumin and sugar.

Mr. A. OGILVY exhibited a most interesting case of "Pemphigus of the Conjunctiva" occurring in a farm labourer, who, for failing health, went to Canada. Shortly after getting there he suffered from pemphigus, the attack lasting for six weeks. He remained well for six weeks and then returned to England at which time he could see to read with ease. On the passage home he had another attack which was very severe. The eyes got rapidly worse and now the corneae were seen to be opaque and the conjunctiva was so shrunken that but little sac remained and the entropion was most troublesome. Lanoline applied to the eyes gave great relief.

Messrs. LAWSON and PARSONS showed a drawing of a case of Sarcoma of the Choroid which occurred in a man, *æt.* 34. He had had a squint for two years and the sight of the right eye had been failing for a year, and when first seen it was almost blind. For 3 months a black swelling has been present on the sclerotic and this was increasing rapidly in size, and had much the appearance of a staphyloma. The eye was blind and the lens was opaque. The eye was removed and on section a large sarcoma was found which was thin and flat and not at all like the choroidal sarcoma that is commonly seen.

Mr. PARSONS gave a lantern demonstration of some cases in which peculiar folds in the retina were found in certain eyes that had been examined pathologically.

Mr. HALLIBURTON McMULLEN showed a child, *æt.* 9 months, who was brought on account of an occasional upward deviation of the eye which had been noticed directly after birth. On examination it was found that there was complete absence of downward rotation of the right eye, the movements in other directions were normal. On looking downwards the left eye fixed, while the right eye was rotated upwards and outwards and was slightly retracted, the eyelid at the same time became elevated and retracted. The inferior rectus and possibly also the superior oblique, was defective.

Mr. R. E. BICKERTON showed a case of Peculiar Changes in the Optic Disc, Retina and Choroid occurring in a patient *æt.* 15. When first seen in July last, he had well-marked neuritis in the right eye with surrounding retinitis. The disc was now raised, it was of a bluish-white colour and had a wool-like margin. There were also numerous fundus changes which were beautifully illustrated by ophthalmoscopic drawings.

Mr. CHARLES WRAY showed a man who had improved considerably while under his treatment for tobacco amblyopia. This treatment he fully described at the last meeting of the Society. It consisted briefly of making such patients take brisk walks and drink large quantities of water.

Messrs. ORMOND and McCASH showed a man who had a piece of metal embedded in the retina.

Mr. R. R. CRUISE showed a patient from whose eye he had extracted a piece of metal with Haab's magnet, and in which some interesting fundus changes were present.

ULSTER MEDICAL SOCIETY.

MEETING HELD IN THE PATHOLOGICAL LABORATORY, QUEEN'S COLLEGE, THURSDAY, MARCH 2ND.

The PRESIDENT (DR. WM. CALWELL) in the Chair.

IN opening the proceedings reference was made to the fact that this annual "laboratory meeting" was held just at the right time to welcome Professor Symmers, who had arrived from Cairo only a day or two before, to take up the duties of the Professorship of Pathology.

Professor SYMINGTON and Dr. HANNA showed several anatomical specimens, including a fine set of young

temporal bones to show the development of the air cells, and some greatly enlarged photographs of the internal ear.

Professor T. H. MILROY read a short paper on "The Exchange of Nutritive Material between Different Organs of the Body, as Exemplified in the Spawning of Fish." The paper, which was exceedingly interesting, was the outcome of an inquiry into the spawning of salmon and herring, made by Professor Milroy at the request of the Scottish Fisheries Board. As is well known, the salmon takes no food after leaving the salt water, and when the ovaries enlarge, they must do so at the expense of other organs. Professor Milroy has shown that the necessary fat is got from various muscles in the fish, but never from those needed for its propulsion. After the expulsion of the ova, the fish begins to improve in condition, and this though it is still not feeding, which change he proved to be due to the assimilation of the degenerating tissue in the ovary, and its reconversion into muscle. The great interest of these observations lies in the fact that in them we can see the interchange of material between different organs, uncomplicated by the addition of nutrient material from without.

Dr. J. A. MILROY gave a microscopic demonstration of some specimens illustrating the structure of the ductless glands.

Dr. R. L. GRAHAM described a case of General Paralysis of the Insane with Meningo-Myelitis, and illustrated his description with a large number of very fine micro-photographs which he had done of vertical and transverse sections of the cord.

Professor BYERS showed a number of specimens of uterine and ovarian tumours, and a series of plaster casts of the foetal head, which he had just obtained from Berlin.

Dr. JOHN CAMPBELL also showed several specimens of similar tumours.

Dr. ST. GEORGE showed two tumours, one a parotid, and the other an axillary tumour. Of these, as well as of many of the other tumours shown, Dr. Wm. Mair showed microscopic sections.

Dr. H. L. MCKISACK showed a ruptured aneurysm of the basilar artery.

Mr. MITCHELL showed several tumours, with sections.

Mr. FULLERTON exhibited a stomach showing gastric ulcer with erosion of the pancreas.

Dr. JAMES LYNASS exhibited charts showing the effects of the serum treatment of erysipelas.

Dr. MARION ANDREWS showed an abscess of the ovary, and also a series of specimens preserved and mounted by the Kaiserling method, the advantage of which is that it preserves the natural colour of the specimen as when it comes from the operating theatre or *post-mortem* room.

Dr. THOMAS CARNWATH read a note on the Value of the Streptococcus as an Index of Sewage Contamination. This was one of the most interesting items on the agenda paper, as Dr. Carnwath imparted "local colour" to his communication by a most lucid account of his experiments with Belfast sewage, illustrating it with a map of the Lough into which the sewage is discharged, and charts showing the varying quantities of streptococci found at different points in it. As the question of the pollution of the shores of the Lough is very much to the fore of late, the paper was listened to with special interest.

Dr. THOMAS HOUSTON demonstrated the method of preparing and administering a vaccine for the treatment of staphylococcal lesions (A. E. Wright's method), and he and Dr. J. C. RANKIN showed preparations demonstrating that the opsonic power of the serum is destroyed by heat at 60 degrees.

At the last meeting of the Society, Dr. Houston showed several cases treated with great success by this method, so that the scientific account of the method and the demonstration of its working were looked forward to with much interest, which was fully justified by the event.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, March 12th, 1905.

INDICATIONS AND COUNTER INDICATIONS FOR THORACENTESIS.

WHEN should thoracentesis be practised in cases of serous effusion, and when should the surgeon abstain from it?

Thoracentesis is indicated, says Schlesinger, firstly when there is danger of death. The grave signs are continued, syncope, thready pulse, cyanosis of the skin and mucous membranes, turgescence of the veins of the neck, deviation of the heart. Secondly, when it is impossible to cure the malady otherwise. If the effusion remains for weeks without tendency to diminish in spite of medical treatment, the operation is imperative. As a general rule thoracentesis should not be practised before the third week and as long as fever exists unless there arises some absolute indication for interference. An operation practised during the febrile stage of pleurisy only gives temporary relief, for the effusion returns. Yet at the end of some days, even if the fever persists and the exudation progresses, tapping cannot be avoided and frequently it has to be repeated. The best chance of success is obtained, however, when the fever has abated, the effusion is stationary and the urinary secretion has diminished.

In hæmorrhagic pleuritis, the operation has sometimes to be repeated frequently. Malignant tumour of the pleura gives rise to considerable effusion, producing intense dyspnoea.

As to accidents, they are only the result of imprudence. Death can follow immediately after the tapping, especially if a large quantity of liquid is removed at once (over three pints); the operation should be done slowly, guided by the dyspnoea of the patient. Death is due to embolus derived from thrombus of the pulmonary veins, and it can be caused by phenomenal cerebral anæmia.

Traumatic pneumothorax is frequently observed after thoracentesis, although not always recognised, but may disappear in three or four days without provoking any alarming symptoms. Sometimes, the patient expectorates a clear, albuminous liquid after the operation.

The canal of the puncture rarely becomes fistulous, and when performed aseptically the serous liquid will not become purulent.

TREATMENT OF FLATULENCE.

Peroxide of magnesium, 6 grs.

For one wafer to be taken half an hour before each meal.

After meals, the following powder:—

- Prepared chalk, 15 grs.;
- Bicarb. of soda, 8 grs.;
- Calcined magnesia, 8 grs.

In case of burning sensation in the stomach and pyrosis:—

- Prepared chalk, 15 grs.;
- Subnitrate of bismuth, 6 grs.;
- Calcined magnesia, 12 grs.;
- Codeine, $\frac{1}{4}$ gr.;
- Powdered belladonna, $\frac{1}{4}$ gr.

For one powder.

Preparations of naphthol should be avoided, as they irritate the stomach.

DIARRHŒA OF CONSUMPTIVE PATIENTS.

- Methylene blue, 3 grs.
- Lactose, 20 grs.

For one wafer, to be given daily.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, March 12th, 1905.

At the Society of Charité Physicians, Hr. Lazarus showed a case of

FRIGHT PARALYSIS,

in which recovery took place in three weeks. After electrification the sensibility returned suddenly over the whole body. Power of movement soon returned after

paradisation of the extremities, and shortly after the power of voluntary movement.

Hr. Greef related a case of

EXTIRPATION OF A RETROBULBAR TUMOUR WITH RETENTION OF THE BULB.

The patient remarked six years ago that one eye was more pronounced than the other. As he declined operation, potassium iodide was given but without result. Some loss of visual power came on, however, so that he returned for further treatment. It was then ascertained that the right eye projected 1.6 cm., the left 2.9. Besides this, the eye was twisted a little outwards and downwards. Vision was reduced to $\frac{1}{4}$, and the field was somewhat limited. There was venous hyperæmia at the fundus. The case was taken to be one of tumour springing from the orbital periosteum. The patient was willing to submit to operation on the condition that the eye itself should be spared. The tumour was removed by dividing the internal rectus muscle and turning the eye out. After the operation the eye was blinded and there was slight ptosis. The tumour proved to be a sarcoma.

He also related a case of

CARCINOMA OF THE EYE-LID WITH RECOVERY BY RÖNTGEN RAYS.

The patient was a man, æt. 61, who had an ulcer on the eyelid that was rapidly destroying it. After extirpation of the bulb, the diagnosis of carcinoma was confirmed, the ulcer was treated by Röntgen light, and recovery rapidly took place.

Hr. Thörner spoke on

OPERATIONS FOR MYOPIA.

He did not seem very much in favour of operative interference. In addition to the known danger of infection there was the risk of separation of the retina and creeping irido-cyclitis. Out of 17 cases operated on, the bulb was destroyed 8 times; in 9 cases the operation did well, vision became sufficiently good, but later on there was enlargement of the image before the eye that had been operated on. The limits for a possible operation were up to the dioptries.

Hr. Greef was of opinion that the operation should be abandoned.

Hr. Wiesener spoke on the

TREATMENT OF TRACHOMA,

the medicinal, mechanical, and the operative. The first consisted in the employment of nitrate of silver or sulphate of copper; the mechanical in rubbing of the conjunctiva with lint soaked in sublimate solution or in scrubbing off with a brush; the operative in destruction of the granules on the conjunctiva. The results of recent treatment with Röntgen and radium rays were problematical.

Hr. Greef was in favour of the mechanical treatment.

The *Deutsch. med. Woch.* has a note on the

USE OF SALICYLATE OF SODA AS A GARGLE.

Six grammes of salicylate are dissolved in 120 of water. A tablespoonful of iron solution is used as a gargle in half a glass of warm water. In violent inflammatory affections the gargle should be used hourly. The pain in swallowing is said to quickly diminish on using the gargle. The anæsthetising effect of the gargle shows itself on the mucous surface of the pharynx as well as of that of the mouth and gums. A dressing soaked in a 5 per cent. solution rapidly relieved the pain of ulcerating chilblains and brought about recovery. In angina with white muco-purulent deposit and in pseudo-diphtheria, the pseudo-membranes disappeared in two or three days. In such cases, however, the salicylate should not be stopped too soon, or the membrane would return. The writer had employed the treatment frequently among the students of the Kriegsschule from 13 to 18 years of age. They came complaining of feeling unwell with temperature varying from 38-39-40; he ordered gargles of salicylate to be used three or four times before they retired to their dormitory. The next morning the temperature was 37° C., and the patients cured. It was an excellent disinfectant wherever used.

At the meeting of the Charité on the 13th ult. Hr. Federmann related a case of

SPLenic ABSCESS WITH OPERATION AND RECOVERY.

The patient was a man recovering from typhoid fever. Leucocytosis had been determined before the commencement of the fever. When the fever had subsided the temperature went up again, and dulness was noticed over the thorax to the left and behind. The speaker found pus in the pleural cavity, resected a rib, and then saw the diaphragm bulging strongly. After he had determined by exploration puncture that there was pus, he incised, when brownish pus came out from a subphrenic abscess. In it were floating pieces of necrosed spleen which were removed. After the fever had existed for eight weeks, the parts healed without a fistula. He considered that the leucocytosis marked the existence of a complicating suppuration.

Hr. Federmann also spoke on the

TREATMENT OF ACUTE PERITONITIS BY HORSE SERUM.

The fact that peritonitis was generally a mixed infection made it unlikely that any specific serum would be obtainable. It would be better to strive to excite a hyperleucocytosis, and in this way to heighten the resistance power of the organism. Horse serum was suitable for such a purpose. This possessed bactericidal properties in a high degree, but this property was mostly destroyed by heating.

He had hitherto used sterilised serum, *i.e.*, serum that had been heated, in 11 cases. The results had not been very encouraging, whether the serum had been injected or introduced into the peritoneum, but he hoped by means of a sterilised serum that had not been heated to be able to obtain better results.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, March 12th, 1905.

HEMANGIOMA VENOSUM CAPITIS.

At the Gesellschaft, Eiselsberg presented a young woman on whom he had operated for a hæmangioma on the head. The patient was *æt.* 17, and from birth had a swelling over the right parietal bone, appearing in the middle line, if history can be trusted. The growth was soft and fluctuating when pressed, and could be moved from its position on the cranium, in which a deep indentation could be felt, which the tumour had produced by long contact with the bone.

The exploring needle revealed nothing but blood, which led to a diagnosis of sinocele, according to the classification of Hæker and Lannelongue, and which Churciens later designated pericranial hæmangioma. After the tumour was removed the diagnosis was confirmed by microscopic examination. The literature of the subject records sixteen cases of this rare affection, observed by Chipault in 1897.

HYPEROSTOSIS OF THE CRANIUM.

Ranzi showed a young woman from whom he had removed a large osteoid tumour about the size of a child's head. It was situated on the left side of the frontal bone and extended along the parietal bone on the same side. The history of its growth seems to have commenced about the fifth month, which at this time appears to have been about the size of a hen's egg over the supra-orbital region. Within the last two years a severe form of exophthalmos appeared with a congested form of the fundus of the eye. After removing the tumour the exophthalmos and congested papillæ disappeared completely, and the wound healed without any untoward circumstances.

SYPHILITIC VACCINATION OF THE CHIMPANZEE.

Kraus gave a record of his experiments in transmitting syphilis to the macacus. He prefaced his remarks with a history of the subject, and thought that Metchnikoff and Roux were the first who succeeded in proving that the syphilitic virus could not be transmitted in the chimpanzee. In support of this conclusion he could now add his personal testimony in its favour after two years' experiments on the macacus. In the anthropoid the primary effects cannot be exhibited, although a localised induration can be effected at the point of insertion, but the general effects are

absent. This sclerosis with secondary papules were observed by Mracek, which he compared with the human sequelæ, but his own observations were that sclerosis in healthy macacus did not appear, and that no incubation period of eighteen or twenty days could be observed, as had been recorded to be typical of the ape. This local hardening seemed to become feebler on every transmission, and it soon disappeared altogether. At this point he showed the sclerosis on a cynocephalic baboon, but no general symptoms had appeared. It had one common symptom with the human sclerosis, which was a tendency to destroy the surroundings.

Neumann said that this was still a debatable question as he could recollect many experimenters during the last century, many of whose results were negative, although a few were confidently affirmed to be positive. For his own part he had to confess that his experiments in 1882 were negative, although those conducted on guinea-pigs exhibited the venereal sores with lymphatic inflammations. He confessed that Metchnikoff, Roux, &c., were the first investigators to put experiments on a scientific basis. Notwithstanding all these negative results syphilis is not solely confined to the human race, as many other animals can be affected. No antitoxic serum can be discovered.

SARCOCELE SYPHILITICA DEXTRA.

Ehrmann exhibited a patient with a sarcocele resembling cancer, which he pointed out could hardly be cancerous, chondromatous or sarcomatous. The glands in the neck and groin were greatly enlarged, and five years ago there seemed to be a history of ulcers on the leg. In September last year the patient complained of alimentary disturbance, such as loss of appetite, vomiting, icterus, and pronounced emaciation. No anti-syphilitic treatment seems to have been prescribed, although the exanthemata indicated late syphilitic grouping. The regular smooth surface of the scrotum was against cancer, chondroma or sarcoma, while the glands of the neck and abdomen were in favour of syphilis. He diagnosed the case as a general infiltration of the fibrous tissue of the scrotum, and therefore indicated syphilitic treatment.

ADRENALIN AND ARTERIO-SCLEROSIS.

Braun next recorded the results of his experiments at the Paltauf Institute, where the question had been asked if intravenous injections of adrenalin produced arterio-sclerosis. His experiments had been largely conducted on guinea-pigs with amyl nitrite. His results pointed to a toxic genesis in the arterial system which produced increased pressure associated with the vascular changes. He pointed out that the therapeutic treatment in reducing the pressure in such sclerosis was only treating the symptom and not the disease itself.

Hungary.

[FROM OUR OWN CORRESPONDENT.]

BUDA PEST, March 12th, 1905.

At the recent meeting of the Budapest Royal Medical Society

Dr. Rác read a paper on

AORTIC INSUFFICIENCY AFTER TRAUMA.

Severe injury may result from the rupture of an aortic valve where atheroma is present, but it is less commonly known that the same may occur in perfectly healthy valves. Aortic insufficiency follows, but extensive vegetation at the tear may also narrow the orifice. It is generally found that an exceedingly loud and rough murmur speaks for a traumatic etiology in doubtful cases, but this is not always so, according to Dr. Rác, who gave the detailed history of a case with a very definite murmur. Sometimes on auscultation, no murmur can be heard at all.

Dr. Lakatos exhibited a case of

SYPHILITIC POLYARTHRITIS.

The patient dates the primary lesion to five years ago. The course of the disease did not seem to be typical,

although the diagnosis is undoubted. A few months before admission to the hospital sudden pain appeared in the left great toe and in the left sole; the next day the pain spread into the ankle of the same side, and in a week the knee-joint was attacked. The pains were especially aggravated at night. Later on the right knee was invaded. Treatment for chronic articular rheumatism, though energetically applied for a long time, failed to produce any results. The epiphyseal ends of the bones at the attacked joints were markedly thickened and tender to pressure. Patient walks with difficulty and pain; is hardly able to flex his knees, and is entirely unable to extend them. Passive movements elicit crepitation. Left shoulder-joint appears to be thicker than the right, and abduction is limited to 45 degrees. The muscles of several joints were markedly atrophied. Rheumatic affection could be excluded in view of the chronic course of the disease, the nocturnal exacerbation of the pains, the absence of any marked alterations in the skin over the affected joints, as well as of any febrile condition during the whole length of the attack, and finally the complete failure attendant on energetic anti-rheumatic treatment. Tuberculosis of the joints was excluded by the multiplicity of the affected joints, by the fact that no purulent exudations were detected in any of the joints, the low temperature and the absence of tuberculous signs anywhere in the system. As a matter of fact the employment of iodide of potassium in conjunction with mercurial ointments improved the condition rapidly and radically. After a series of injections the patient began to feel better, gained 23 pounds in weight and walked with comparative ease. The author is inclined to consider this polyarthritis as belonging to a late period of syphilitic manifestations. The patient very likely entered the hospital at the period of transition from the secondary to the tertiary stage; and it was because of this that the mercurial treatment in conjunction with iodine was more effective than the iodine alone, as employed in the beginning.

Dr. Adolf Erdős (Nagyvarad) read a paper on.
**ANTISTREPTOCOCCUS SERUM IN ERYSIPELAS AND
 PUERPERAL SEPSIS.**

The results of the employment of anti-streptococcus serum published so far are so contradictory that no definite idea can be formed as to its utility as a therapeutic agent. Dr. Erdős presented two cases of erysipelas and two cases of puerperal sepsis, in which he used the serum. The first was a typical case of facial erysipelas in a woman, *æt.* 50. The disease was in its fifth day of development, spreading rapidly and unyielding to various remedial agencies such as carbolic acid, ichthyol, &c. When 20 c.cm. of antistreptococcus serum were injected, improvement followed the next day, and in the course of a week the patient was rapidly convalescent. In the second case the favourable results of the injection manifested themselves on the third day. Of the puerperal cases the first became septic soon after delivery; when seen by the physician, during the third week after confinement, she presented typical signs of sepsis, pain in the uterus, daily sweating, offensive lochial discharge, abdomen somewhat distended and very painful; 20 c.cm. of the antistreptococcus serum were injected, followed on the next day by a double dose; improvement was gradual, but undoubted, and in the course of a month the patient was discharged well. In the second case, that of an adherent placenta that necessitated extraction, sepsis was quite pronounced during two weeks, at the end of which an injection of the serum was made; but as improvement was not observed, and the supply of the serum was exhausted, routine treatment was resorted to, until a new supply of the serum was injected on the fifth day. Unfortunately, the results of the treatment became obscured through an unexpected complication of pneumonia. However, the patient eventually recovered with a somewhat diminished mobility of the uterus. Notwithstanding the small number of cases in which the serum was employed, the results obtained are undoubtedly interesting, and may lead to further trials.

NORTH-WEST LONDON HOSPITAL.

REMOVAL OF A LARGE VESICAL CALCULUS.—Mr. MAYO COLLIER operated on a man, *æt.* 43, the subject of calculus of the bladder. The patient had complained in the last few months of frequency of micturition accompanied by pain before, during, and after micturition. The man had previously sought advice at a hospital three months ago, saying then that he had caught a chill, and complaining of the same symptoms but in a mitigated form. The ordinary remedies for cystitis were at that time administered with considerable abatement of symptoms and corresponding comfort to the patient. This improvement, however, was not permanent, and the case was admitted into the hospital under the care of Mr. Mayo Collier. The patient was a pale, thin, badly-developed individual; he was a house painter by trade. There was no evidence of gout or of over-use of alcohol. The heart and lungs were apparently healthy, and nothing abnormal was discovered in the abdominal viscera beyond the trouble in the bladder. A diagnosis of stone had previously been made in the out-patient room. Mr. Collier said that on admission he did not pass a sound to confirm the diagnosis on account of the extreme irritability of the bladder. The patient having been placed under an anæsthetic, a small sound was introduced into the urethra, but its introduction to the bladder could not be accomplished without some difficulty. The beak of the sound on its entrance to the bladder immediately encountered a stone whose presence was audible to all the bystanders. With difficulty the sound could be introduced some two or three inches during which the grating of the stone was never absent. Mr. Collier remarked that he believed that this was a very large stone, and decided on performing the suprapubic operation. An incision some three inches in extent was made in the middle line above the pubes (after the bladder had been injected with some four or five ounces of fluid); the recti being retracted, the pericyclic fat was easily exposed, and the outer wall of the bladder reached. On the introduction of the scalpel into the bladder, its point struck a stone immediately under the mucous membrane of the viscus. It was now found that the bladder was extremely small, much thickened, and was almost completely filled by a hard, very large calculus. The opening into the bladder was enlarged as much as possible, and an attempt made to introduce the finger so as to free the stone from its surroundings. By the introduction of a pair of ovum forceps the stone could not be lifted from its bed. Mr. Collier directed his assistant to pass his finger into the rectum and endeavour to raise the stone into the opening of the wound so as to enable him to shell it out with the assistance of a rough elevator. After some considerable trouble the calculus was extracted, and proved to be a hard uric acid stone having much the size and appearance of a large potato; some scales and spicules that were detached during the manipulations were removed and a large drain inserted. Mr. Collier said this was one of the largest stones (its weight 3.025 grains, or nearly 7 ozs., its longest diameter nearly 4 ins.) he had seen removed from a bladder; and it was remarkable, he thought, that this patient could have got about with the few symptoms he had

complained of. That it must have existed for some time was presumable from the fact of the extreme contraction and thickening of the bladder. The chief difficulty in its removal, he remarked, was due to the limited opening at his disposal, but by careful dilatation and stretching the parts the stone was ultimately delivered without much damage to the surrounding tissues.

In spite of an extremely critical condition of heart failure and hypostatic congestion of both lungs following the operation, the patient has rallied, and a fortnight after the operation is advancing toward convalescence.

TOTTENHAM HOSPITAL.

UNUSUAL CAUSE FOR RECTAL HÆMORRHAGE IN A BOY.—Mr. H. W. CARSON operated on a boy, æt. 11, who had been admitted with the following history:—Three days before admission he had severe hæmorrhage from the rectum unaccompanied by pain or other symptoms. The hæmorrhage recurred on many occasions, and the boy began to suffer from the effects of loss of blood. The bowels were open before the first hæmorrhage, but had not acted again before admission; there were no signs of intestinal obstruction. On admission the boy looked pale, but was in no discomfort. A loss of bright blood occurred soon after he entered the hospital. Rectal examination was negative except that the rectum was ballooned. On examining the abdomen there was no distension, but a tumour, one inch in long diameter, was felt in connection with the sigmoid flexure. This lump was freely movable across the axis of the intestine, and was tender on pressure. The boy was otherwise apparently healthy. The probable diagnosis of polypus was made and in view of the fact that the boy was evidently suffering from loss of blood, it was decided to open the abdomen and deal with the condition as was found necessary. On the abdomen being opened, the sigmoid was found to be bound down by a broad, firm adhesion fixing the meso-sigmoid to the pelvis; at one point the adhesion extended as far as the gut, where it caused an acute kink. Palpation of the sigmoid proved that there was no polypus. The lumen of the gut was easily restored by separating the adhesion. The abdomen was then closed. Mr. Carson said that the cause of the adhesion was obscure, the only abnormality present being a number of small shot-like glands in the meso-sigmoid. He considered that in this case the hæmorrhage was due to the kinking of the sigmoid causing acute hyperæmia of a portion of the lining mucous membrane of the gut. He thought it was very probable that intestinal obstruction would have soon supervened. Discussing the causes of rectal hæmorrhage in children, he pointed out that it is comparatively rare, and when present almost invariably due to polypus. In making a diagnosis in this case the most likely causes of trouble seemed to be either a polypus in the sigmoid flexure or an intussusception. The former appeared the more probable owing to the character of the hæmorrhage, which was arterial in appearance, whilst the absence of any signs of intestinal obstruction would render the presence of the latter very doubtful.

A few hours after operation the boy passed a small quantity of blood and from that time he had no further symptoms. On his leaving the hospital three weeks later the lump was no longer palpable, and the patient declared himself as feeling quite well.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, MARCH 15, 1905.

THE REFORM OF THE IRISH MEDICAL ASSOCIATION.

IN our recent articles on Surgeon-General Evatt's report on the Irish Poor-law Medical Service, we indicated that we should in our next issue return to what is at the present moment the most important matter in Irish medical politics, namely, the reform of the Irish Medical Association. This body needs not alone the support and work of its active members, but also the healthy stimulus which friendly criticism can give. It is admitted on all sides that the reform of the Association is a pressing matter, and that what ought to be an influential and important body can no longer be allowed to remain in its present unsatisfactory condition. The Association brought over Surgeon-General Evatt at great expense to report on its present condition and to suggest reforms. By one of those unfortunate “accidents” that are too common in Irish affairs, the absurd and impracticable portions of his report have become public, and have attracted general notice and adverse criticism, while the portion from which the Association may not unfairly expect to receive benefit is as yet an official secret. It may not be out of place if, while the Council of the Association debates the treatment to be awarded to the remainder of Surgeon-General Evatt's report, we place before our readers the nucleus of a scheme of reform, which may serve to turn in a suitable direction the thoughts of those on whom the actual drafting of a reform scheme must devolve. Constructive criticism is always difficult, and in this case it is beset with special difficulties, while a purely destructive criticism is valueless. Two items of destructive criticism we may, however, bring forward. The Irish Medical Association should not be nominally governed by an unwieldy Council of some seventy members selected not

by branches, nor by county representatives, but by the whole body of the Association; nor should it be actually governed by a Committee or Council of eight members, of whom five are the medical officers of the same Union. What should be substituted for these bodies, the one suffering from the inertness of mass, the other from the over-activity of almost complete independence? We should like to see the Association reorganised in some such manner as this:—Every member should be attached to a county Branch, whose business should be to promote social intercourse between its members, to send representatives to a Provincial Council, and to report to the Provincial Council on all local matters affecting the welfare of the profession. The Provincial Council should consist of representatives sent forward by the Branches. Its duties should be to elect representatives for a General Council, to bring before the General Council all matters with which it was not itself empowered to deal, and to administer such portion of the funds of the Association as was allocated to it, and which should represent a certain percentage of the subscriptions of the provincial members. To this Provincial Council should also be given the power of fixing the salaries of, and general conditions under which, Poor-law and other medical appointments should be held, with the safeguard of the right of appeal to the General Council of any member who might feel himself aggrieved. The General Council should consist of the President of the Association and of representatives sent forward by the Provincial Councils. It should meet quarterly and when occasion required. It should control the funds of the Association, save such portion as should be allocated to the Provincial Councils, and with it should rest the final decision on, and responsibility for, all measures undertaken by the Association as a whole. The Central Council should consist of two representatives from each Province, and so, with the addition of the President of the Association, would consist of nine members. The Provincial Councils should consist of ten representatives from the Branches, and so, with the addition of a Provincial President, would consist of eleven members. The Branch representatives should be elected on an automatic system, based on the number of members of each Branch. The points in this scheme which appear to us to be most important are as follows:—First, the Provincial Councils are entrusted with the management of all provincial affairs up to a certain point, and with the control of a certain proportion of the funds collected in their own provinces. Secondly, the Central Council is elected by representative men from among their own number, and so the suitability of its members is twice tested, and only those men are selected who are likely to take an active interest in the affairs of the Association. Thirdly, the Central Council is of reasonable size, and is thoroughly representative of all parts of Ireland.

THE EXCLUSION OF SCOTCH AND IRISH DIPLOMATES FROM ENGLISH HOSPITAL APPOINTMENTS.
